This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

MOTOR WORLD

Buy Right.

ONE of the unfortunate features of the handling of accessories by dealers and garagemen is that many of them find themselves stocked up with goods which seem to be unsalable. These include all sorts of things, from rinky-dink attachments to make the car do this or do that to compounds and quack prescriptions that have a bad case of shivers every time they see a blue sky law.

The garageman and dealer has bought unwisely The question of price does not enter into the situation at all. He has been "stuck" by a clever salesman or has let his enthusiasm run away with him. In all probability he has bought from a company of which he knows little or nothing and whose product is in the same class.

The garageman and dealer should be careful. He should stick to goods he is pretty sure he can sell—well-advertised goods— *Motor World, Dec. 1, 1915.*

The AUTOMOBILE

Switching Off the Spotlight

For the First Time in Sixteen Years the New York Show Discloses Attention Centered Upon Whole Car Rather Than Upon a Part

By A. Ludlow Clayden

NEW YORK CITY, Jan. 1.—A new régime in automobile shows began last night when the sixteenth annual automobile show was opened in Grand Central Palace. When the doors opened there was ushered in a régime wherein the spotlight, which has dominated all past shows, was switched off.

In the great public spectacles that the development of the automobile has staged since the birth of the twentieth century there have been many acts and many scenes. Through all of these the spotlight has been busy flicking from one mechanical feature to another, from four-cylinder motors to sixes, from bevel drive to eight-cylinder motors, from motors to starters, from starters back again to motors. Each successive annual show had its star performer of the mechanical company, fit subjects for the spotlight, but to-day we have reached a point where the full cast, linked arm in arm, bursts into a general chorus, where each member is singing the same song. The scenic and the physiological effects depend no more upon the principals than upon the supers.

It is no final curtain, the last stage of development, for the last act lies far away, but we have reached a period in the great play that marks an epoch in the making of the story. That this was so needed not the declamation of the show to establish it as fact, but the show itself removes all doubt, all argument. It is the first automobile show in history displaying automobiles acclaimed for what they are and what they will do, instead of for how they are made and for what pieces are used in their construction. In a word, engineering development seems to have reached a stage where it is taken for granted. The buyer need no longer exercise judgment so much as taste.

Engineering Quality High

That the average engineering quality of the chassis exhibited would surpass all previous shows was a foregone conclusion, yet it is surprising how great has been the advance from the high standard set a year ago. In 1915 the critical visitor, admiring the general progress, was ever and anon, brought to a stand before some relic of the past; some clumsy, ill-conceived, ill-executed car. To-day there is scarcely one such to be found on the four floors of the Grand Central Palace show with its 326 cars and chassis on exhibition.

Last year the leaders of development set the standard high, but the followers have made the leap required and the assembled ranks present the most solid front yet seen, not only in America, but in the whole wide world.

It was not in any one particular that the standard was raised. To-day we do not see the limelight on motors, on transmissions or on springs. The perfect automobile is a collection of perfect parts, and all parts are of equally great importance in the ultimate. For the first time, so it seems, this is realized, and it is especially to be noticed that the show visitors exhibit no curiosity about any particular feature. True, there are some new cars that all are anxious to see, there are some stands which are continuously thronged, but the people have gone there to see the *car*—not to see a portion of it.

General view of the central court on the main floor of the sixteenth annual New York automobile show being held in Grand Central Palace. The entire scheme of decoration consists of dark-colored draperies between the dual Corinthian columns which in themselves are a feature of the building. Overhead is a generous hanging of flowers and foliage on the cornices and chandeliers. The exhibits illustrated above bring out the variety of body styles which is a feature of the exhibition. The columns on the second floor are treated in Renaissance figures and pergola effects. The third floor where the accessory exhibits are for the most part situated is designed to give a Japanese garden impression, an idea of this scheme of decoration being given in one of the other illustrations showing this great accessory division with its aisles bordered by exhibits of all sorts

As a sight to attract the eye the show is a good one, but the feeling cannot be avoided that there is a lamentable lack of sensibly colored cars. It cannot be good merchandising to fill a stand with somber black, it does not catch the eye, but is it not equally poor business to use as an attraction some glaring monstrosity of color? The all-black stand the visitor may pass by, at the one with the brilliant car he halts, but he is seldom so impressed from a buying viewpoint as by a stand with two or three different colored cars which are of hues suitable for use. There are more chassis than ever before, mostly finished in a quiet paint which shows them off far better than any other method—actually of the 326 cars fifty-six are stripped chassis— and there is hardly a maker of importance who does not show all detail of his car.

Accessory Field Consolidating

In accessories it is to be observed that those shown are mostly of a more solid character and mostly exhibited by reputable firms. There is a notable absence of cheap devices of the tin can order, which have been prevalent at many former exhibitions—especially, perhaps, is evidence of this settling down process to be noticed in the Ford accessories, most of them being of the really useful sort.

One misses, however, the majority of the leading component makers. Axles and transmissions, clutches and starters are used extensively as selling arguments for the assembled car, and the show provides the opportunity for the manufacturers of these essential parts to show why their names are renowned. The maker of parts derives his success from the public, indirectly if you like, but it is from the public that it comes, and the public is interested in what the parts makers are doing. Ignition is well represented, carburetion well displayed; why not all the other sections of automobile makeup?

Bodies for Every Taste

Apart from generalities, undoubtedly the great feature of the show is the wide choice of bodies. Hardly a manufacturer but has a half dozen styles to choose from; the quality of his chassis established, he has turned to the study of the public's multifarious tastes. Last year one noticed the streamline touring body, the smooth outline, the spacious interior; this year the finest group of touring bodies ever gathered together in America can be seen, yet they do not impress the mind so much as the many other varieties which have grasped places of prominence.

Leaders among the newcomers are. of course, the small four-seated car, the large three-seated body and the inexpensive closed machine. All are easy targets for criticism since all have their faults as well as their virtues. Many a man who sighs for the cosiness of a clover leaf, four-passenger will find it hard to select one wherein cosiness is not obtained at the expense of knee cramp, or where leg room has been fashioned with detriment to the appearance or to some other feature. A few there are that seem well nigh perfect, but as yet it is but a few.

Then with the cheap closed cars. and the convertible types especially, the excellent examples stand out clearly from the rest. These things are natural, they are not noticed at first glance, they appear only on close examination, the faults will vanish in another year; on the whole, so far as the clover-leaf bodies are concerned, it is remarkable that so many good ones have grown up in a single year.

In body quality the greatest variations are to be found among the convertibles, the touring cars that will inclose completely. Of these a few can, when in the closed state, hardly be distinguished from a real closed car; some would be quite indistinguishable when on the street, but others look all of the makeshift that they are, clumsy, ill-designed and badly made. The good examples show what *can* be done. The rapid adaptability of the American manufacturer will soon raise the average to the height of the present peak, and the future of this body style depends entirely upon whether the car owner will treat the convertible body as he does his home, regarding the task of attaching the top much as he looks upon that of getting the furnace into service for the winter.

And here a mild grumble on the fully closed car that is not meant to open, this being that not infrequently the comfort of the interior depends upon the scope remaining *after* the outer lines and form have been fixed. A prettily curving roof may easily so meet the back panel that a passenger can only wear a hat by adopting a crouching attitude. This is very far from being usual, but it is noticeable in a sufficient number of instances to make this comment really deserved.

Folding Seats in Transition

Not so long ago the folding seat of a seven-passenger touring car was always rather in the way, rather ugly and rather liable to rattle. To-day we see many bodies in which the presence of the seat when folded is difficult of detection. Iron bars and brackets lying about the floor or walls of a tonneau are out of place; they do not harmonize with soft upholstery and velvety carpets. A piano would give as sweet music without its polished case, just a bare skeleton of frame and wires, but it would be out of place in a living room. It is now about twelve months since the automobile body designers woke up to this, and how busy they have been is easy to see. As usual some have been successful to a much greater degree than others, but on the whole the congratulations of the public are due unstintedly.

More Rigid Chassis

Hand-in-hand with body development has gone relief of body strains, this being sought by so increasing the strength of the chassis frame that it will protect from injury the more delicate structure that it supports. Deeper and wider sections are the rule, and more frames have been widened so as to bring the side rails almost as far apart as the sides of the body at their widest. This is supposed to prevent racking strains, by broadening the base of body platform, and putting the rear springs beneath the side rail instead of outside it removes some twisting stress. The wide frame is not universal by any means, but it is being largely used in the attempt to overcome the tendency to the development of body squeaks after a long period of use.

Better Springing

Spring mounting has undergone a great change, having, it is obvious, become a study of mechanics instead of an accident of assembly. It is not so much the type of spring as the details of its shape and the brackets which attach it. Engineers have closely studied the forces involved and schemed to meet them to best advantage. The subject is a wide one, far too wide to discuss within the limits of a show review, but it should be noticed by the mechanically intent. In a nutshell, the 1916 car is better balanced.

Not the least remarkable thing is the decreased interest in motors. With the finest selection ever got together before their eyes, the show visitors evince a marked interest in neatness of design, in convenience of arrangement, but far less than last year in the number of cylinders or the main mechanical features. A strikingly designed four attracts as much attention as a twelve, a well constructed six draws a bigger crowd than a poor eight. The thing is impressive only to one who saw the shows of years ago, especially, perhaps, that of last year. Then to have an eight was to block the surrounding aisles all day, but the twelves in the present show, while drawing many, have nothing like the same magnetism. They are, of course, not so new as was the eight a year ago, but the impression persists that there is more than this in it; that no mystery now lurks in multiplicity of cylinders. The V motor of however many cranks and pistons is an accepted thing whose virtues are known and realized just as widely as those of the six or four.

In the making of the automobile, in the changing of it from a mechanical toy to a necessity of civilization, we first sought effectiveness, and it was obtained. Next reliability was the goal, only to be won after years of hard struggle. Then came docility—quietness, flexibility, ease of handling, and to this many years were given. Then came the more petty things which may, when lumped together, come under the head of convenience. Ease of starting, protection against weather, luxury of appointment in all their ramifications come under this classification.

For a time this last became a madness, robbing the car of engineering qualities, adding to it new possibilities for trouble, but now; now we see a proper balance struck. Whatever price we may choose to pay for an automobile we can write the check with confidence that we are buying our full money's worth in automobile service to our desires and expectations.

The spotlight is out for this scene. The footlights are burning at full power, the whole stage, the chorus and the leaders make one great picture complete in itself and dependent upon no single, glittering figure for its effect.

The Year to Come

What is to be read in the show of to-day as an augury of the future? The question is none too easy to answer; it may be that this removal from special prominence of any particular feature of a chassis is but temporary, that next year we shall find the spotlight very much in evidence. But it seems more probable that this will not be the case. To review the past, the earlier things of outstanding remark, such as six-cylinder motors and, afterward, starters, were things that really made for better motoring. Because of the six-cylinder motor we were able to obtain certain refinements at reasonably low cost, because of the starter we were able to increase the comfort and convenience of motoring to a substantial degree.

But the later parts of prominence have been of much smaller actual importance. The eight and twelve-cylinder engines have not made a tithe of the difference that was caused by the starter, and it is difficult to foresee anything which could again break right away from the standard practice of the times. Perhaps a two-stroke motor boom year may be in store for us. Perhaps an electric transmission year is scheduled by the fates, possibly we may even live to see a year in which two wheeled cars will have a vogue, or cars with front wheel drive. Perhaps the gearbox will be abolished for something better, but the greater probability is that development henceforward will be gradual—that we have done with the spotlight.

Above—The first view of the show that every visitor entering the Palace obtains, with Overland and Buick in the best exhibit spaces.

Below—General view of accessory division on fourth floor of Grand Central Palace show. The pillars are inclosed with bamboo matting.

Many New Cars—Few Surprises

While Show Affords First Opportunity for Examining Many New Cars, No Novelty of a Startling Nature Was Reserved Till the Show Was Opened

IF the New York show, 1916, contains less of novelty in chassis design than did its immediate predecessor, there are none the less plenty of interesting new cars to be seen there for the first time. Most of the twelves are new models entirely. There is the Marmon six with its light weight construction and aluminum motor. There is the Moline with the same type of frame as the Marmon and also a motor almost all aluminum. The Hudson Super-Six is the newest of all, perhaps, but the Peerless eight, the Scripps-Booth eight and the Cunningham eight are also cars which have been announced quite recently.

Similarly the Paige company has a new six and there is a new model Case and in fours we have the Briscoe, the Sterling and the S. J. R., the former with a new model, the last two named with entirely new cars. Other companies new to the industry exhibit the Lescina cars and the Sun six, while the one foreign car in the show, the Irish Fergus chassis is especially interesting from the engineering viewpoint. Of this list the majority have been described in THE AUTOMOBILE within the past few months, and redescribed briefly in last week's show number. It remains to add the details of the few which are left outstanding.

Hudson Super-Six Has Unique Motor

THERE has been much speculation as to the details of the new Hudson six, which makes its appearance at the show. Interest especially centers in the motor, which is the first to be built by the Hudson company itself under its own roof, and it is evidently destined to mark a new epoch in Hudson development, for with the same bore and stroke as that of the previous model it develops 80 per cent more power. That is, whereas the Six-40 was considered a good example of six-cylinder practice, delivering a maximum of 42 hp., the new engine with the same displacement of 288.6 cu. in. and the same bore and stroke of 3½ by 5 in., develops a maximum of 76 hp.

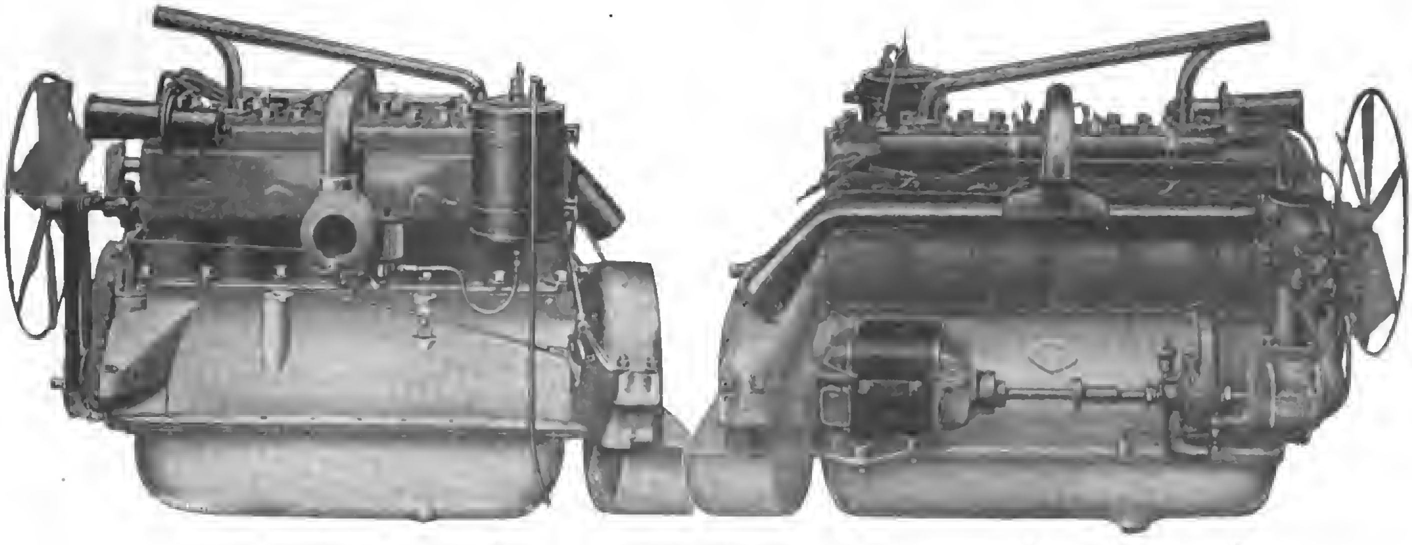
Of course, the engine is a higher-speed type than the previous design, running upwards of 2600 and 3000 r.p.m., this having to do with the added power. The main point of attack seems to have been the crankshaft, and recognizing that vibration has been a limiting factor in high-speed engines, the Hudson engineers set about to get rid of the trouble by revising the shaft construction, the result being a patented system of eliminating vibration so as to get an engine of high mechanical efficiency.

General practice is adhered to throughout the other details of the engine, although, to take care of the higher speed, the valve openings have been increased considerably, and the four crankshaft bearings have been enlarged as compared with those of the Six-40.

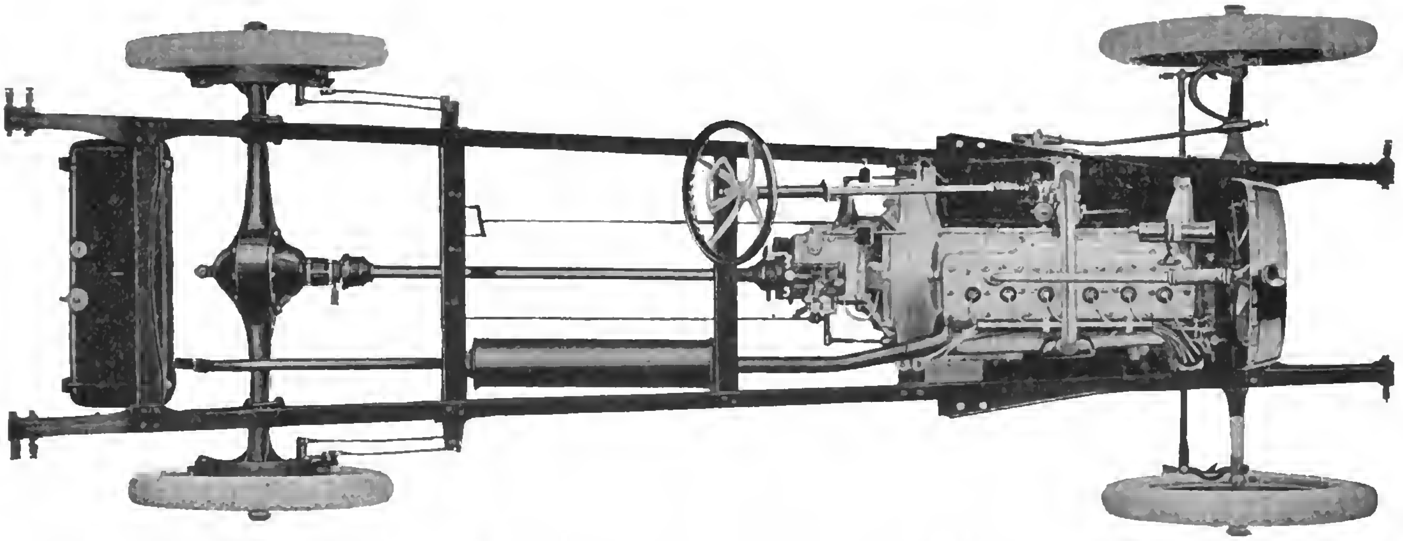
Tests Show Unique Acceleration

That the new designing ideas of the Hudson company have proven fruitful is evidenced from the fact that the new car, under supervision of the A. A. A. has broken all stock car records up to 100 miles, its official weight without passengers, but with tanks full, being 3164 lb. For the hour it covered 75.689 miles with two passengers, and with five passengers and top and windshield up the distance covered was 70.742 miles. The fastest laps of the 2-mile Sheepshead Bay track, where the tests were made, were during the hour trial above referred to, and these laps were both made in 1 min. 33.8 sec., which figures to an average speed of 76.75 m.p.h. These tests therefore give to the new Hudson all the stock car records from 5 to 100 miles for machines with motors of from 231 to 300 cu in., displacement, and they further present it with the hour record regardless of class.

The official A. A. A. report also shows the accelerative possibilities of the car to be remarkably good. From a standing start, the touring model carrying three passengers attained a speed of 60 m.p.h. in 23 sec., and reached a 50 m.p.h. gait in 16.2 sec. Starting from 5 m.p.h. in high gear, it reached 30 m.p.h. in 10 sec. and 50 m.p.h. in 19.4 sec. The chairman of the Committee on Tests of the A. A. A. has



The Hudson motor which develops exceptional power for its size has nothing external to disclose the fact. In the above views the excellent valve accessibility and the peculiar carbureter are well shown



Cleanliness of outline characterizes the Hudson Super-Six chassis. Aft of the motor the 1916 car is very much like the 1915 model, except that the rear end of the frame is shaped somewhat differently

certified that the car used was a stock model in every detail, and it is very evident from the figures above given that the engine is destined to upset many ideas that the maximum horsepower per cubic inch displacement was attained with sixes heretofore produced.

Car Is But Little More Costly

Although the new car is vastly superior to anything before built by Hudson, it sells at about the same price as before in the open models, the figure being $1,375, which is $25 more. There are four attractive closed-body types at figures ranging from $1,675 to $2,500. Body designing has not been lost sight of in the attention that has been paid to the engine, and the body lines are entirely new, departing from the yacht-line idea of the former Six-40. The radiator is higher, and the body lower with more room, especially in the front compartment. As compared with the Six-40, the wheelbase is 2⅛ in. greater, being 125⅛ in. The passengers sit lower in the car, and there is the popular double cowl effect. That is, there is a sort of modified dash, finished the same as the body sides, in place of the seat backs formerly constituting the division between the two compartments, this construction having numerous advantages.

Carbureter Is Hudson Design

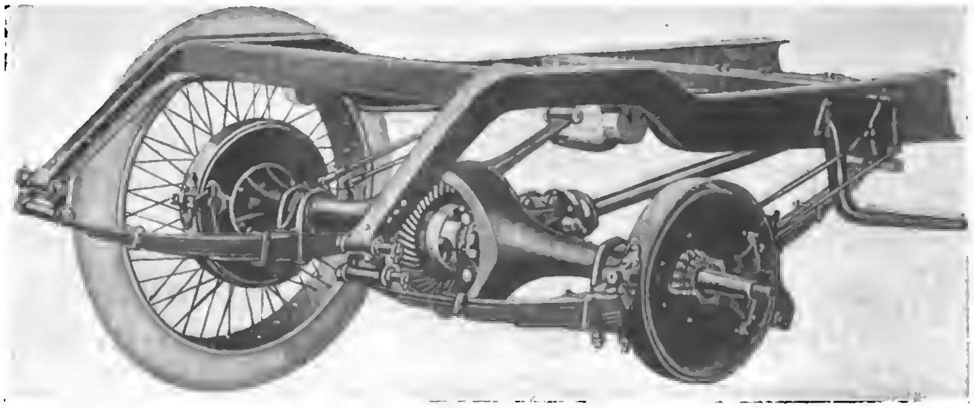
Among the other differences in the car as compared with the previous model are, in addition to the entirely new design of motor, a new carbureter designed by Hudson, which is a type operating pneumatically. The Delco starting and lighting system is new, the gasoline tank is removed from the cowl and located at the rear in connection with Stewart vacuum feed and there is a new rear spring suspension of semi-elliptic type instead of three-quarter elliptic, with a corresponding change in the rear of the frame. Such details as the three-speed gearset in unit with the engine, the multiple-disk clutch and the Hotchkiss type of drive remain practically the same as in the previous model.

Accessibility Is Noteworthy

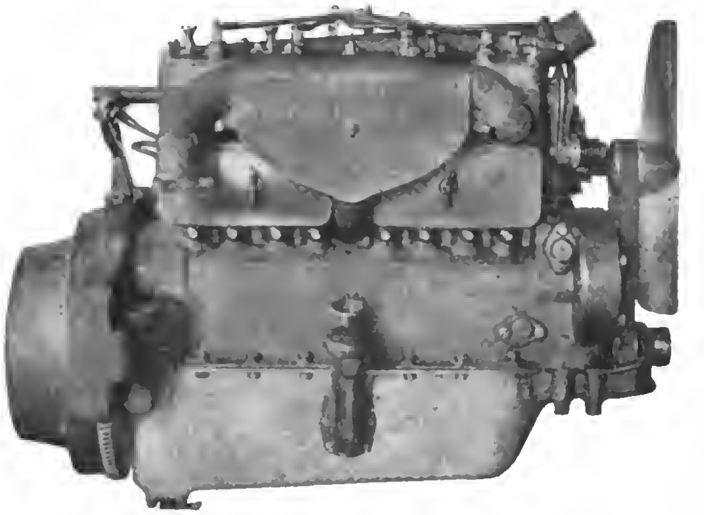
Special attention has been paid to the accessibility of the engine, the arrangement of the units being with this in view. The engine is a conventional L-head poppet valve type in outward appearance, and it has a feature new to Hudson construction in the removable cylinder head, although the usual practice (where the head is detachable) of casting the upper half of the crankcase with the cylinders is not employed. Hudson gives two reasons for the detachable head: it facilitates cylinder casting and gives better cooling which is required by the large valves. It is pointed out that it would not be practicable to use port plugs of a conventional type without sacrificing much valuable cooling efficiency through the increased area of the walls and reduction of the water spaces.

Oiling System New

Naturally, an entirely new oiling system had to be developed for this engine, due to its greater speed and power. This is termed a circulating, constant-level splash arrangement and the capacity is very large, totalling over 3 gal. The reservoir is at the bottom of the engine, the pressed steel pan being quite large, and exposed so as to afford good cooling to the lubricant. The oil pump, mounted at the front of the engine, draws the oil from the reservoir through a screen and delivers it to the front compartment containing the timing gears, and from here it flows into the first oil trough under the first cylinder. The large splasher on the end of the connecting-rod practically empties this trough at every revolution, throwing the oil into suitable channels on the side of the reservoir and crankcase. The upper channels feed the main bearings continuously, and the lower conveys it to No. 2 trough, from which it goes on back suc-



In order to accommodate the long, semi-elliptical springs the ends of the Hudson frame are dropped much lower than usual. This construction interferes very little with the body fitting cessively through the other troughs to the last cylinder, and thence to the reservoir again.



The motor of the most recent Case chassis has the carbureter on the off side, and an extra large muff or hot air collector embraces the exhaust manifold

As the connecting-rod dippers would splash more oil at high speeds than at low, it was necessary to control the stroke of the pump so that the flow might be increased proportionately to cope with the more rapid circulation. To take care of this, the carbureter throttle is interconnected with the pump in such a way as to regulate the pump plunger stroke. The action is simply attained by means of an eccentric and a very large pump plunger. At low speeds the eccentric holds the plunger away from the operating cam, but it allows the plunger to come closer to the cam as the speed increases. Thus the pump has a short stroke when the engine is operating slowly, but when the throttle is opened the stroke is lengthened accordingly.

Water Pump Bolts to Cylinders

In the cooling system, aside from the refinements such as the increasing of the fan diameter and the making of the radiator core and shell separate, there is one especially notable feature. This is the construction of the water pump so as to eliminate any pipes or hose connections between the pump and the cylinder casting. The pump bolts directly to the face of the cylinders and the water passage leading to the jackets is cast integral with the cylinder block. The cylinder outlet connection, with two branches leading from the head, reverts to the brass pipe form so as to insure a certain amount of flexibility and unrestricted water passage, along with quicker repair possibilities than would be obtainable were the water outlet cast as a part of the head.

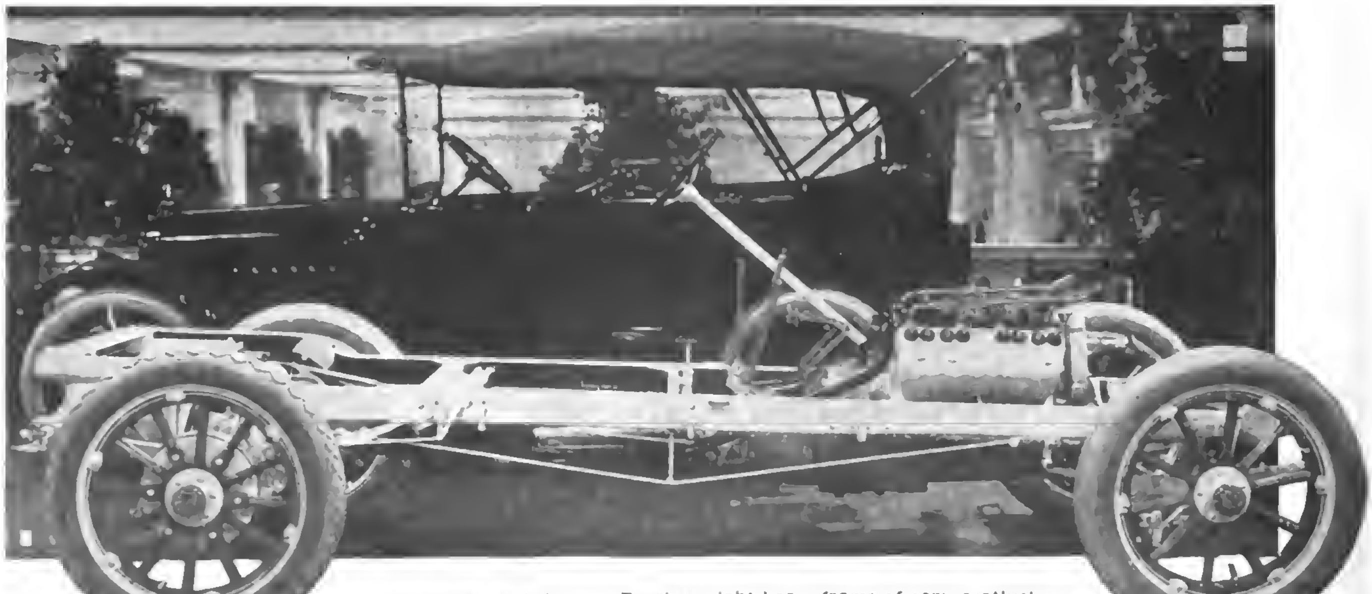
Delco ignition, as well as starting and lighting, is still used, but distributer is placed vertically on the right forward side of the engine and is entirely independent of the motor-generator. There is an automatic governor controlling the operation of the ignition advance, as on Hudson cars for the past 2 years, and by it the manual control is given a spark advance range from full retard to a position which would correspond with firing on dead center under normal road conditions. But from this point on to full advance the spark control is automatic, taking it out of the hands of the driver. The motor-generator occupies the right rear side and is driven from the pump shaft. To facilitate the lining up of the generator, it is piloted in the crankcase supporting arm.

Reverting to the chassis, the characteristic Hudson simplicity is found, and with practically no design alterations in the gearset, the tubular driveshaft or the rear axle with its spiral-bevel gears, the new rear suspension claims special attention. The springs, semi-elliptic in form, are in direct line with the side members and taper toward the front, affording a direct support for the body and frame. It is explained that the half-elliptics are employed because they permit of greater length and that means practically a flat spring which affords great flexibility with minimum weight.

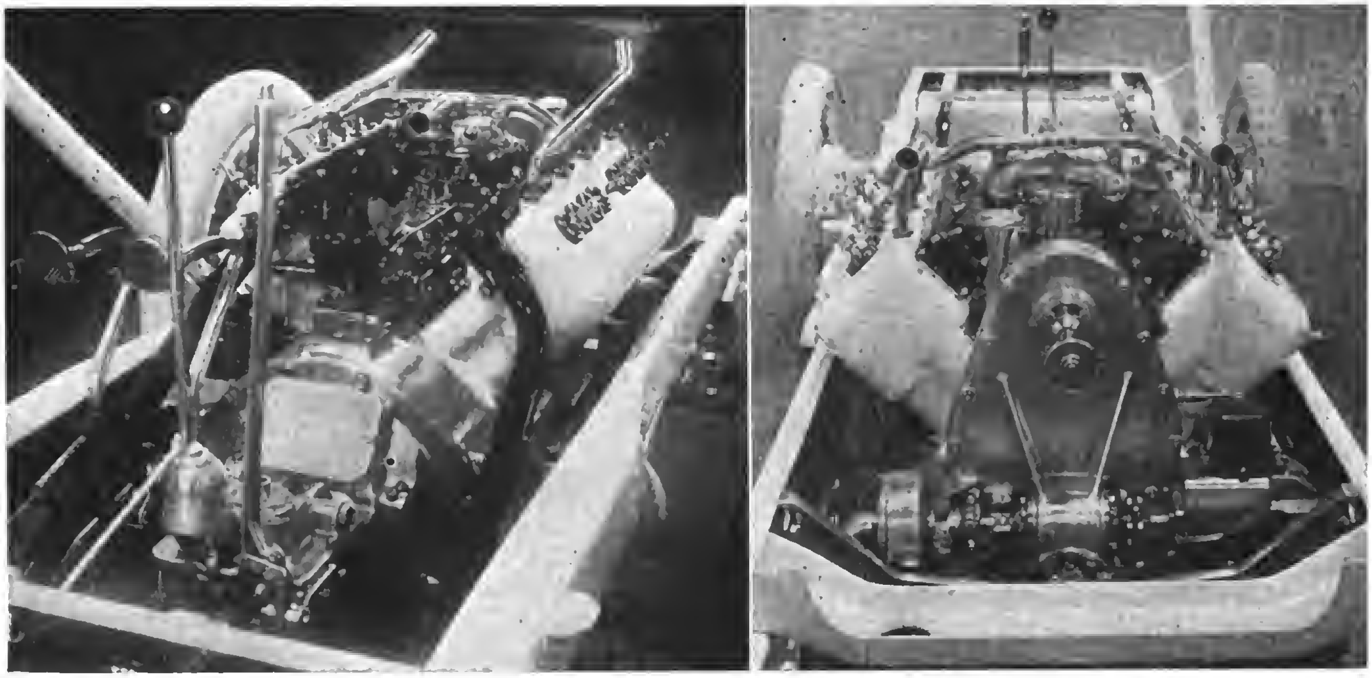
Springs of such length could not be three-quarter elliptic as they would have excessive side sway.

An outward noticeable point is the rearward inclination of the windshield at an angle of about 30 deg. This gives better appearance, reduces the length of the top, and kills reflections. It is also claimed that the vertical shield centers the draft and the dust on the back of the driver's head, whereas the slanting shield seems to carry it over the car, and offers less resistance.

A production of 30,000 of the Super-Sixes is planned for the year, and deliveries have already begun. The name



The chassis of the new Peerless eight has a frame of comparatively light section, the necessary strength being given by a truss rod and post stay bracing. The peculiar water outlet pipe with four branches is shown in this view and it can be seen that each branch attaches to the cylinders adjacent to an exhaust valve.



A noteworthy feature of the Peerless eight motor is the good arrangement of the accessories. The generator and water pump occupy opposite ends of a cross shaft in front, the distributer is well placed at the rear end of the V and the tire pump is at the other end, where it does not interfere with the valves

Super-Six, by the way, has been registered in the patent office.

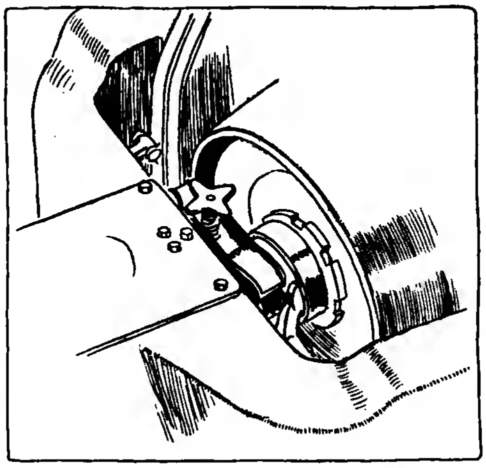
Peerless Is Thorough Design

IN the last issue of THE AUTOMOBILE some general particulars of the new model Peerless were given. It is a 3¼ by 5 in. eight with 125-in. wheelbase and the touring car sells for $1,890. Broadly, the design is not conspicuous for any departures from conventional good engineering, but the detail is worked out with much care and a great deal of skill. The engine is that type of eight in which the cylinders are staggered just enough to permit the use of side-by-side connecting-rod bearings, has a three-bearing crankshaft with exceptional bearing area, and L-head cylinders, its most impressive feature being the spaciousness of everything about it. There is ample room for everything, no accessories are crowded together, and every essential part is really accessible.

In the V is the carbureter, of course, and just in front of it the tire pump, as this is a small enough part not to interfere with the valve tappet accessibility. The pump has a very simple clutch, as its spindle carries a hexagon head and the back end of the fan spindle has a hexagon cup to match.

The oil filler cap stands on the right well to the front of the motor, and the water pump and generator are situated at right and left ends respectively of a cross shaft, which is driven from the crankshaft and lies low across the front end of the crankcase. The cranking motor is on the side of the crankcase, at the right, engaging the flywheel with a Bendix pinion.

The carburetion system is rather interesting, and the instrument itself is a duplex pattern of special design, and feeds into manifolds that are also duplex, there being four ports in each cylinder block which are divided across the center, the upper passage going to the exhaust valves and the lower to the intake. The manifold has thus two parts, the upper for exhaust and the lower for intake, and the gases are kept well warmed without the need for any waterjacket for the intake system. Battery ignition is employed, the distributer being at the rear end of the V on a vertical spindle driven off the camshaft.



Proper functioning of the clutch brake is of great importance for easy gear shifting. The new Case has the hand brake adjustment shown here

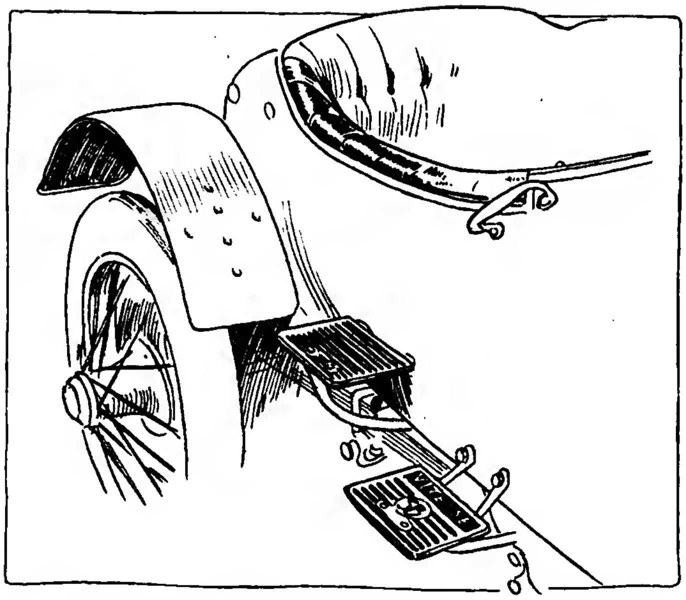
Lubrication is by pressure, all the bearings having a forced feed. Another feature of the power plant, which combines the three-speed gearset, is the remarkably light pedal pressure needed to release the dry disk clutch, since there is a multiplying system of levers between the pedal and the actual clutch striking fork.

Peculiarity is also noticed in the frame of the car, as this is a fairly light section, strengthened by a king post and truss rod on each side. This system of construction gives great strength with little weight, and it is surprising that it has not been used more extensively. The rear axle, with a pressed steel casing and spiral bevel gears, is quite conventional, as is the brakework, but the latter is noteworthy for the care with which the operating rods have been laid out so as to give ample rigidity. None of the pedal pressure is lost anywhere through whip or spring in the connections.

The body of the touring car emphasizes that the car is the product of a firm of repute and long standing. It is an entirely modern type of flush side design but free from any extremes of fashion. As would be expected of a Peerless car, the finish is everywhere thoroughly excellent.

Cunningham Has Fine Body

THE Cunningham eight, designed and built in the parent factory, is the product of a firm who prides itself upon the handsome bodies it can build, and the main feature of the exhibit is a small touring car of unique exterior. There is nothing freakish about the job which is easiest described as a combination of the streamline type with the boat body. All horizontal lines seen in side view are straight, and a light



The body of the Scripps-Booth "Vitesse" model is entered by aluminum steps attached to the side. The passenger has two of these and there is a single one on the driver's side

bead runs from end to end about 5 in. below the top of the side wall. From this point upwards the sides "tumble home" to use the marine expression, that is they are rounded over so that they curve smoothly into the cross section of the front and center cowls. The seats are not divided, but the backs are molded slightly to make a division between driver and passenger, and between the rear seat occupants. Finished in dark, dull gray and with wire wheels the car gives a good impression of power and solidity.

The Cunningham eight-cylinder motor is 4¼ by 5 in., it has detachable cylinder heads and is set rigidly in the frame, the aluminum crankcase having four stout supporting arms. The Brown-Lipe transmission, which is bolted to a bell housing on the motor carries the Westinghouse starting motor on its side and the tire pump is set high up on the fan bracket, so the V is fairly clear of parts and the valve mechanism reasonably accessible. There is a particularly wide center bearing, the cylinder castings being provided with a large waterway between the middle bores, and the oil is put in through fillers located on the heads of the cylinders midway of their length. Altogether the engine is extremely robust and in keeping with the rugged chassis.

The rear axle is a heavy pattern Timken, and is provided with a massive pressed steel torque arm which is anchored to the frame by a short leaf spring, and the frame itself has an exceptional section. Three-quarter rear springs are used. With touring body the price of this new eight is $3,750.

Scripps-Booth Features Bodies

OF the Scripps-Booth eight particulars were given a week ago and the exhibit is designed to feature the complete cars rather than the chassis. The eight is but little larger than the four having the compact Brush-Sterling motor which is the same type as the Ferro and was illustrated by sectional drawings in THE AUTOMOBILE review of 1916 motors of Nov. 4.

Having overhead valves with very simple adjustment for the tappets, the space between the cylinders is not required for any adjusting process, and it therefore serves as an ideal place for the single unit lighting and starting apparatus. The complete eight still looks a quite small car, though a trifle greater in height than the four, and it has the same style of body.

Among the types exhibited there is a particularly striking speed model called the "Vitesse." It is rounded, high sided roadster, with the usual Scripps-Booth staggered seating, and has no doors, a couple of aluminum steps on the side giving access to the seats over the side. With very small mudguards front and rear and no running boards the car has a most rakish look.

Of the other cars, different body styles of less unconventional design are shown, and these differ little from the 1915 type. One alteration is abandonment of the quilted leather finish of the cowl board in favor of the more customary polished wood. In all the car has been improved considerably in both appearance and comfort by changes of small detail.

Haynes Twelve Neat Design

THE Haynes twelve-cylinder engine differs from the six considerably. The crankcase is similar and is interchangeable with that of either six, so far as fitting in the frame is concerned, but the valves are overhead, being operated from a central camshaft and long push rods. Each cylinder block has its valves in a detachable head, and the rocker mechanism is inclosed by aluminum covers, there being four of these in all. Tappet adjustment is on the ends of the rockers and is therefore very easy to make. A Delco distributer and ignition unit of much the same horizontal type as that used on the Packard engine, is mounted at the rear end of the motor, driven off the camshaft and the Leece-Neville generator is in tandem with the water pump on the crankcase side, just as on the Haynes six. The starting motor is located somewhat differently, being provided with a flywheel engagement.

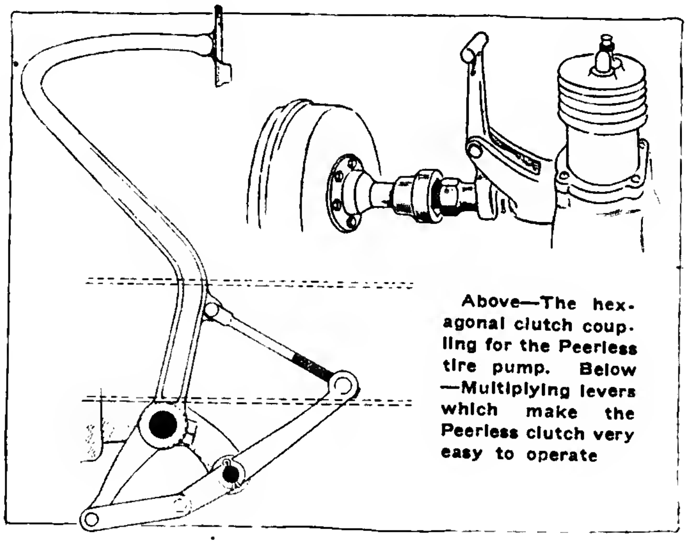
Oiling is by pressure throughout, and the pistons are aluminum alloy, the engine being intended for high speed. With bore of 2¾ and stroke of 5 in., the displacement is 356 cu. in. and the stroke to bore ratio 1.62, much above the average of American practice. The engine can be supplied instead of the six in either of the two Haynes chassis the specifications of the complete cars being otherwise unaffected.

H.A.L. Has Weidely Motor

THE second new twelve at the show is exhibited in touring car form and has the Weidely motor which is precisely similar to the engine as originally made. The body is a spacious seven-passenger type with high, straight sides and the radiator high and narrow with a squarish top, the impression given being distinctly speedy. Full specifications and other details are not yet in sufficiently definite shape to permit a more extended description.

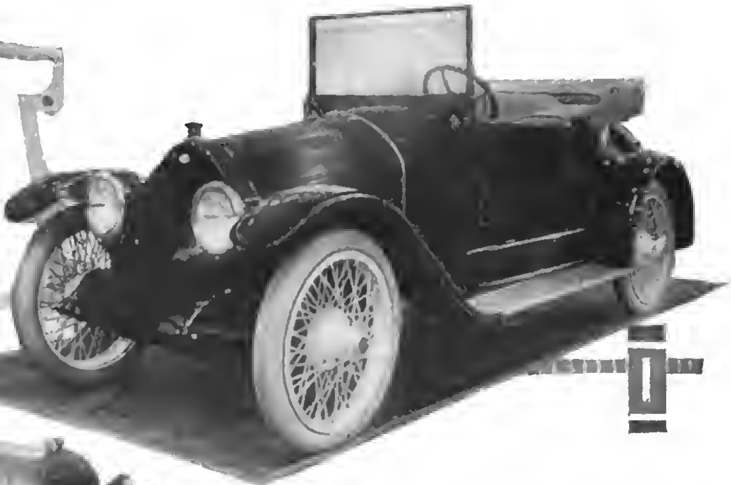
Sun Makes Own Motor

SINCE the announcement of the formation of the Sun company during last summer, a design has been developed, and the model car is shown for the first time. It will be built



Above—The hexagonal clutch coupling for the Peerless tire pump. Below—Multiplying levers which make the Peerless clutch very easy to operate

SAMPLES OF SHOW BODY WORK

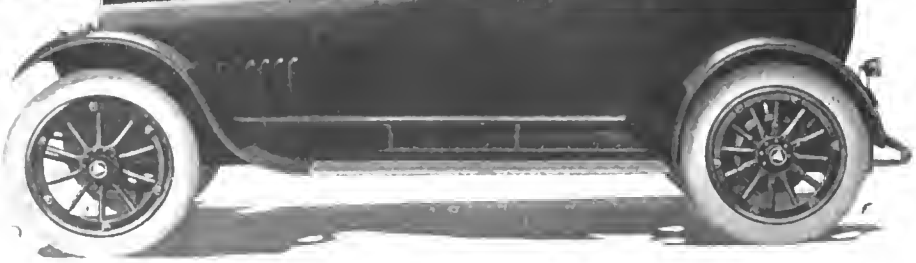


The roadster in which the driver sits slightly forward of one or two passengers who are accommodated side by side is almost as popular as the clover-leaf type. This Mitchell gives a good idea of the neat proportions obtainable

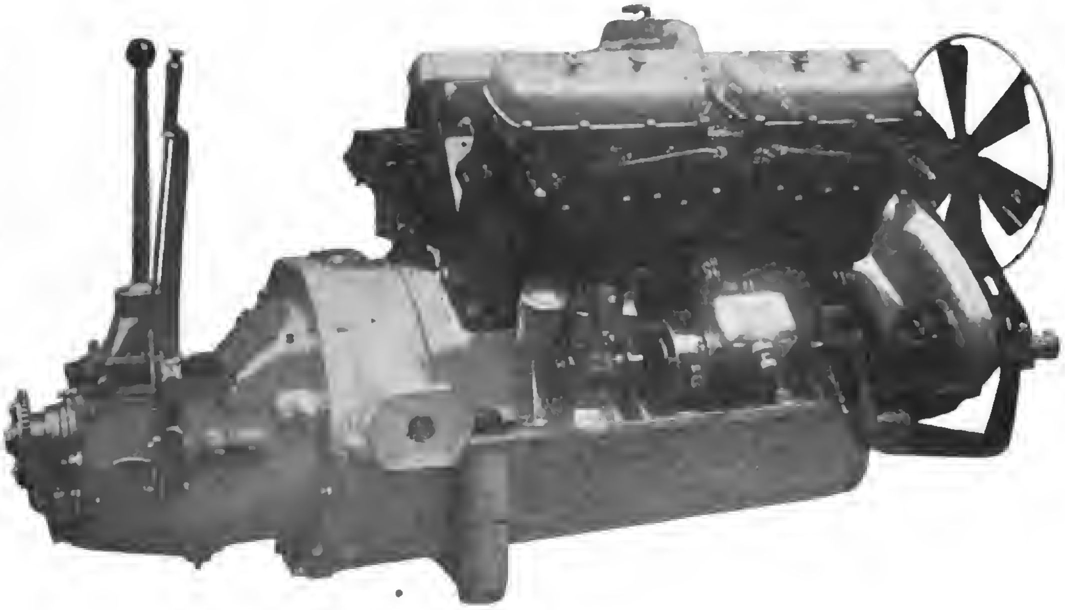
The Cunningham boat-shape body on the new eight-cylinder chassis. Note that the sides of the body are rounded inward at the upper edges so as to bend smoothly into the center cowl

The Scripps-Booth "Vitesse," a much admired speed body in bright yellow coloring. Entrance is obtained by means of the cast aluminum steps on the side

The recent craze for black and white decoration was seized upon by several manufacturers desiring an original finish. This example was one of the best and was exhibited by the Paige company. The paint is dead white, even to the wire wheels



The Hudson Super-Six is shown with several styles of body. This town car is quite typical of modern bodies of its class and is one of the best designed in the show from the combined viewpoints of appearance and comfort



The Haynes twelve is a motor interchangeable with the sixes. It is an extremely neat overhead valve design with a long stroke and small bore. It may be observed that the exhaust manifold discharges into the pipe at its center and not from the end

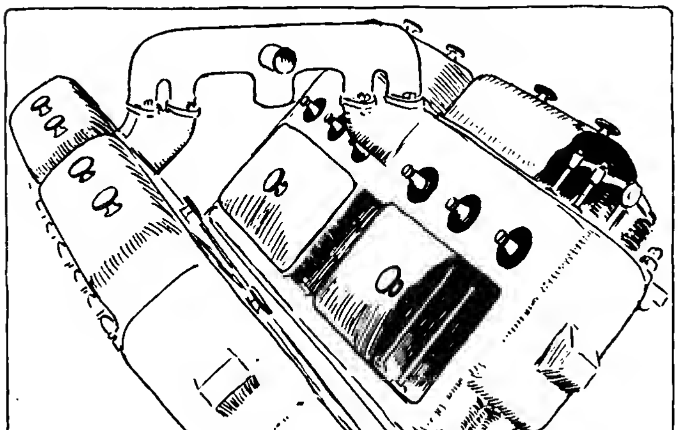
at Elkhart, Ind., and production will commence almost at once. The price of the five-passenger touring car will be under $1,000 but is not yet settled definitely.

The motor is a 3 by 5-in. six made in the Elkhart plant and having several special features. It is a block-cast job with crankcase in unit with the cylinders, and its chief outside peculiarity is that the exhaust manifold discharges into the pipe midway of the cylinders instead of at the end. At the center of the manifold a special part of the casting takes care of the hot air supply to the carbureter, which bolts to the cylinders direct on the opposite side of the block.

For the valves a finger tappet is used, something like that of the small Overland, and all the valve mechanism is thus both inclosed and lubricated. Oiling is by a flywheel system in which the lubricant is forced into the pipes by the centrifugal action of the wheel. It is stated that this motor has the highest compression of any stock motor.

Cooling is thermo-syphon and fuel feed the Stewart vacuum system, while the electrical equipment is to be Remy two-unit, the distributer being mounted in combination with the generator.

Another novelty is the use of a pressed steel "banjo" which is bolted between the crankcase and the gearbox in the middle of the bell housing, the ends of the banjo making the rear motor support on the frame. The rear axle is a floating pattern with pressed steel casing, springs semi-elliptic all around and the tires 34 by 4 in. Production will commence with a neat five-passenger touring car like that exhibited, and a roadster will be added very shortly afterwards.



The Haynes twelve has the valve rockers inclosed by aluminum covers and the push rods are also protected by cover plates of the usual kind. Note the accessibility of the spark plug

Lescina Fours and Sixes

SEVERAL of the Lescina fours and sixes are exhibited, these having been assembled in Chicago, but it is the intention of the company to open a factory in Newark, N. J. The cars will be assembled from good quality components, the precise make of which is not yet settled. The program calls for ten different types of bodies including touring, roadster and clover leaf passenger cars and a light delivery or express wagon. The frames are very wide so as to give the best possible support to the bodies.

The seven-passenger six is listed at $1,212 and the five-passenger four at $888, roadster bodies being alternative at the same prices. Ward Leonard lighting and starting is used.

Sterling Four Very Clean Chassis

SELLING for $595 with roadster equipment the Sterling is a new car in which low cost has been obtained by studied simplicity. The powerplant is a Sterling 3 by 4¼ in., with overhead valves and well lubricated rocker arms. A detachable head gives ready access to the valves.

Carburetion is taken care of by a Zenith instrument which is carried on the right side of the motor. The intake gases flow across the top of the head of the cylinder to the valve openings which are on the opposite side of the head from the intake port. Ignition is by the Wagner battery system in which the current is furnished from the storage battery and the balance of the system is made up of the Wagner distributer mechanism and a high-tension coil. The distributer drive is from the forward end of the timing gears which provides an accessible location. The high-tension coil is mounted on the side of the motor, giving very short connections between the breaker distributer mechanism and the coil.

Splash lubrication is employed, the oil being carried in the bottom half of the crankcase.

The clutch is a leather cone, and the gearset, which has ball bearings, is bolted to the crankcase by two arms that embrace the flywheel. Starting and lighting is performed by a two-unit system, the generator being driven by silent chain, and the motor making engagement by a Bendix pinion.

The frame is very wide, so that the cantilever springs at the rear can be mounted directly beneath it, thus giving direct support to the body. A neat rear axle is employed, this having wide brake drums with two sets of shoes in each, so there is no external brake, both service and emergency being expanding.

Anti-Rattle Devices For Quietness

Many Factors Aid — Coil Springs Popular for Brake Link Support

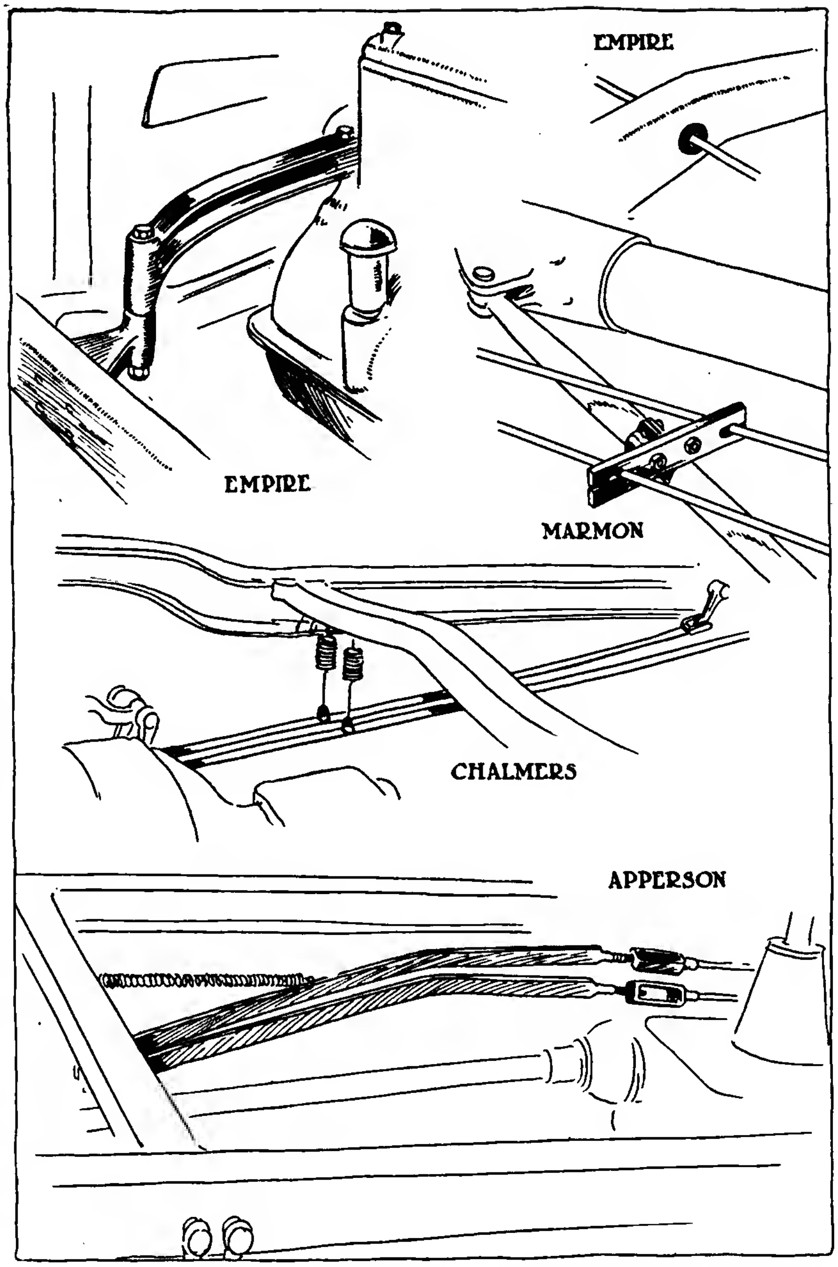
QUIETNESS in the motor would be unavailing unless provisions for quietness are made throughout the entire chassis. A study of the cars at the show reveals the fact that great strides have been made this year in cleaning up the little details which tend to develop rattles after the car has been in use for a time.

The result of this concentration on quietness is that the chassis of 1916 is cleaner than that of 1915, because it has fewer links and material better disposed in every particular. What few links there are are all provided with anti-rattling attachments, generally in the shape of coil springs which are always under tension and which prevent the motion of the car setting up a swinging or vibrating action in the links, causing noise.

Some good examples of how these coil springs have been applied to the links are in the Peerless, Cunningham and Hupmobile chassis. The Peerless makes use of springs which are quite lengthy to hold the brake links from moving while the car is in operation. On the Cunningham eight chassis there are double coil springs on the links.

Rectangular Link Rods

On some of the cars instead of using links and rods of ordinary circular section the sections are rectangular and either carried with the long axis horizontal or vertical. Apperson uses a link of oblong section with the long axis carried vertically, giving a very rigid connection for the brakes and at the same time these are rendered proof against rattling by the installation of very stiff springs. Chalmers has the bar link carried horizontally. The continuous rod which runs from the brake lever directly to the rear axle, where an equalizing attachment is located, is quite popular on many of the 1916 cars. These straight rods either pass backward clear of all the constructional detail on the frames or they may, on the other hand, pass through one of the cross members by means of a hole drilled for the purpose. When the latter method is used the rods are sometimes insulated from the cross member of the frame by a rubber ferrule which prevents the rod from striking against the cross member. In the majority of instances this long rod will pass below the cross member a considerable distance and there is no danger of any clash between the rod and the frame member.



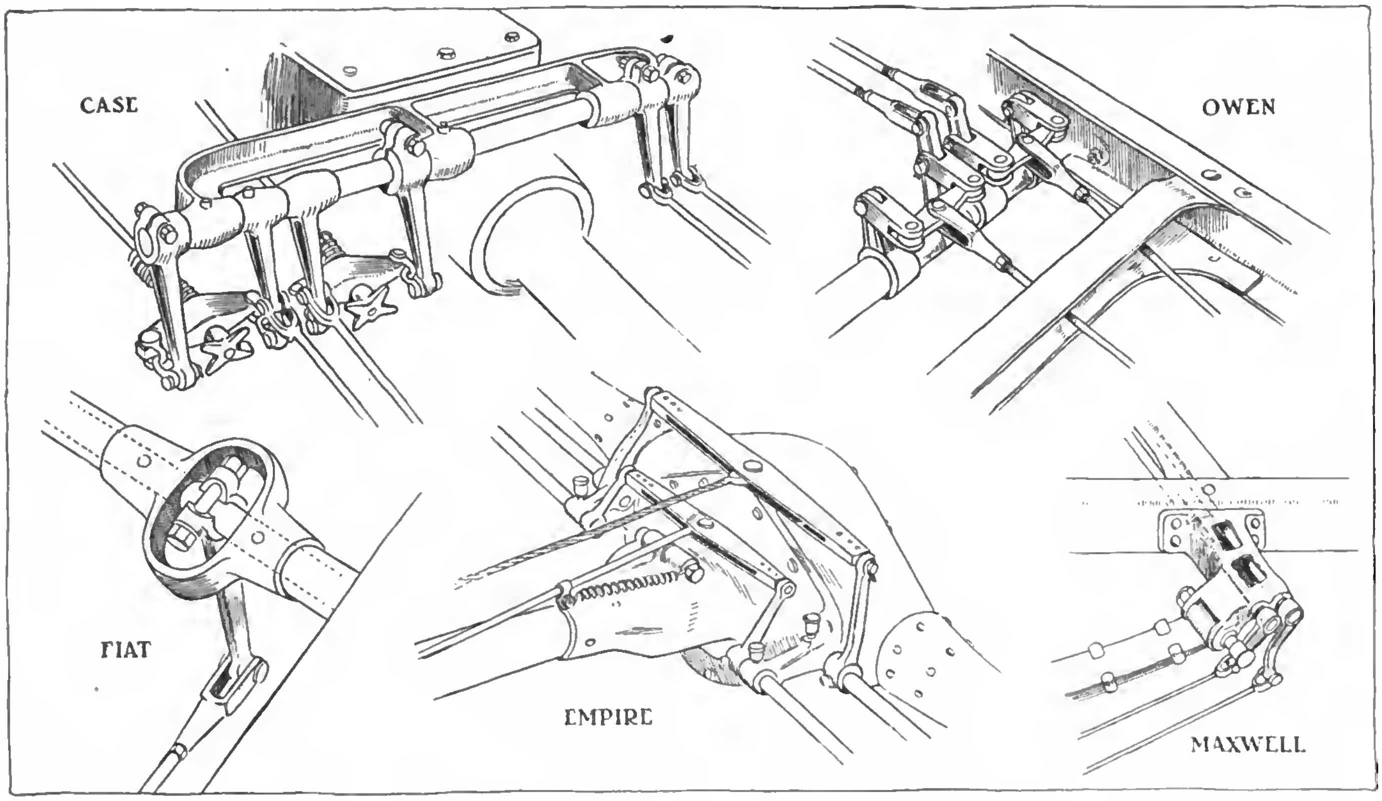
ANTI-RATTLING devices selected at random from miscellaneous cars at the show. The Empire motor support, Empire rubber insulated brake rod, Marmon wiring support, Chalmers coil spring link supports, Apperson rectangular section brake rods with coil spring. These are a few of the means taken to prevent the linkages of the car from developing noise after a few miles of travel.

Rigid Motor Mountings

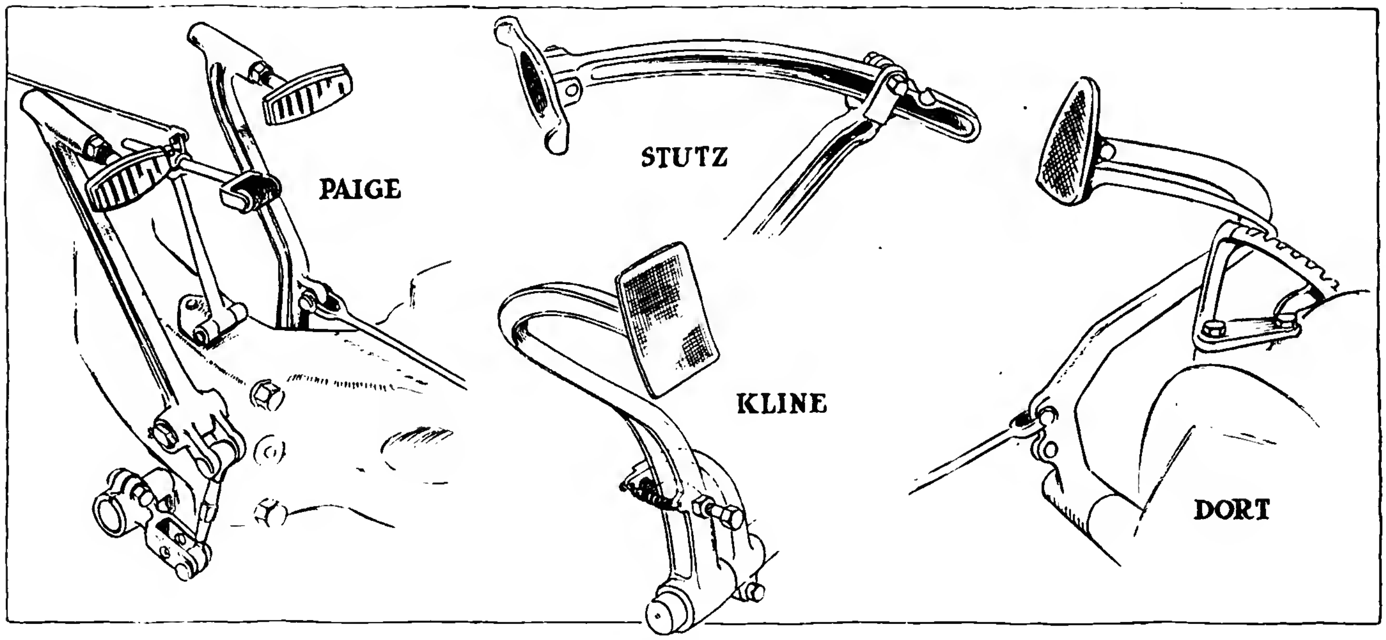
One of the interesting examples where minute detail has been taken care of will be noted on the Velie chassis, where any danger of the gasoline line rattling against the frame or other parts of the car is guarded against by means of small double eye-clips. The double-eye serves a two-fold purpose, one eye taking care of the gasoline line and the other providing a rigid fixture for holding the electric wire conduit in position.

Rigid motor mountings for the rear support, even in the three point suspension jobs, are important in the prevention of squeaks and rattles which are apt to develop if there is any working action between the supporting arms and the frame. The rear support of the motor is quite frequently anchored inside the channel beam on the 1916 cars instead of resting on the upper flange. With the unit power plant the rear supporting arms can be carried back further than on the separate unit jobs.

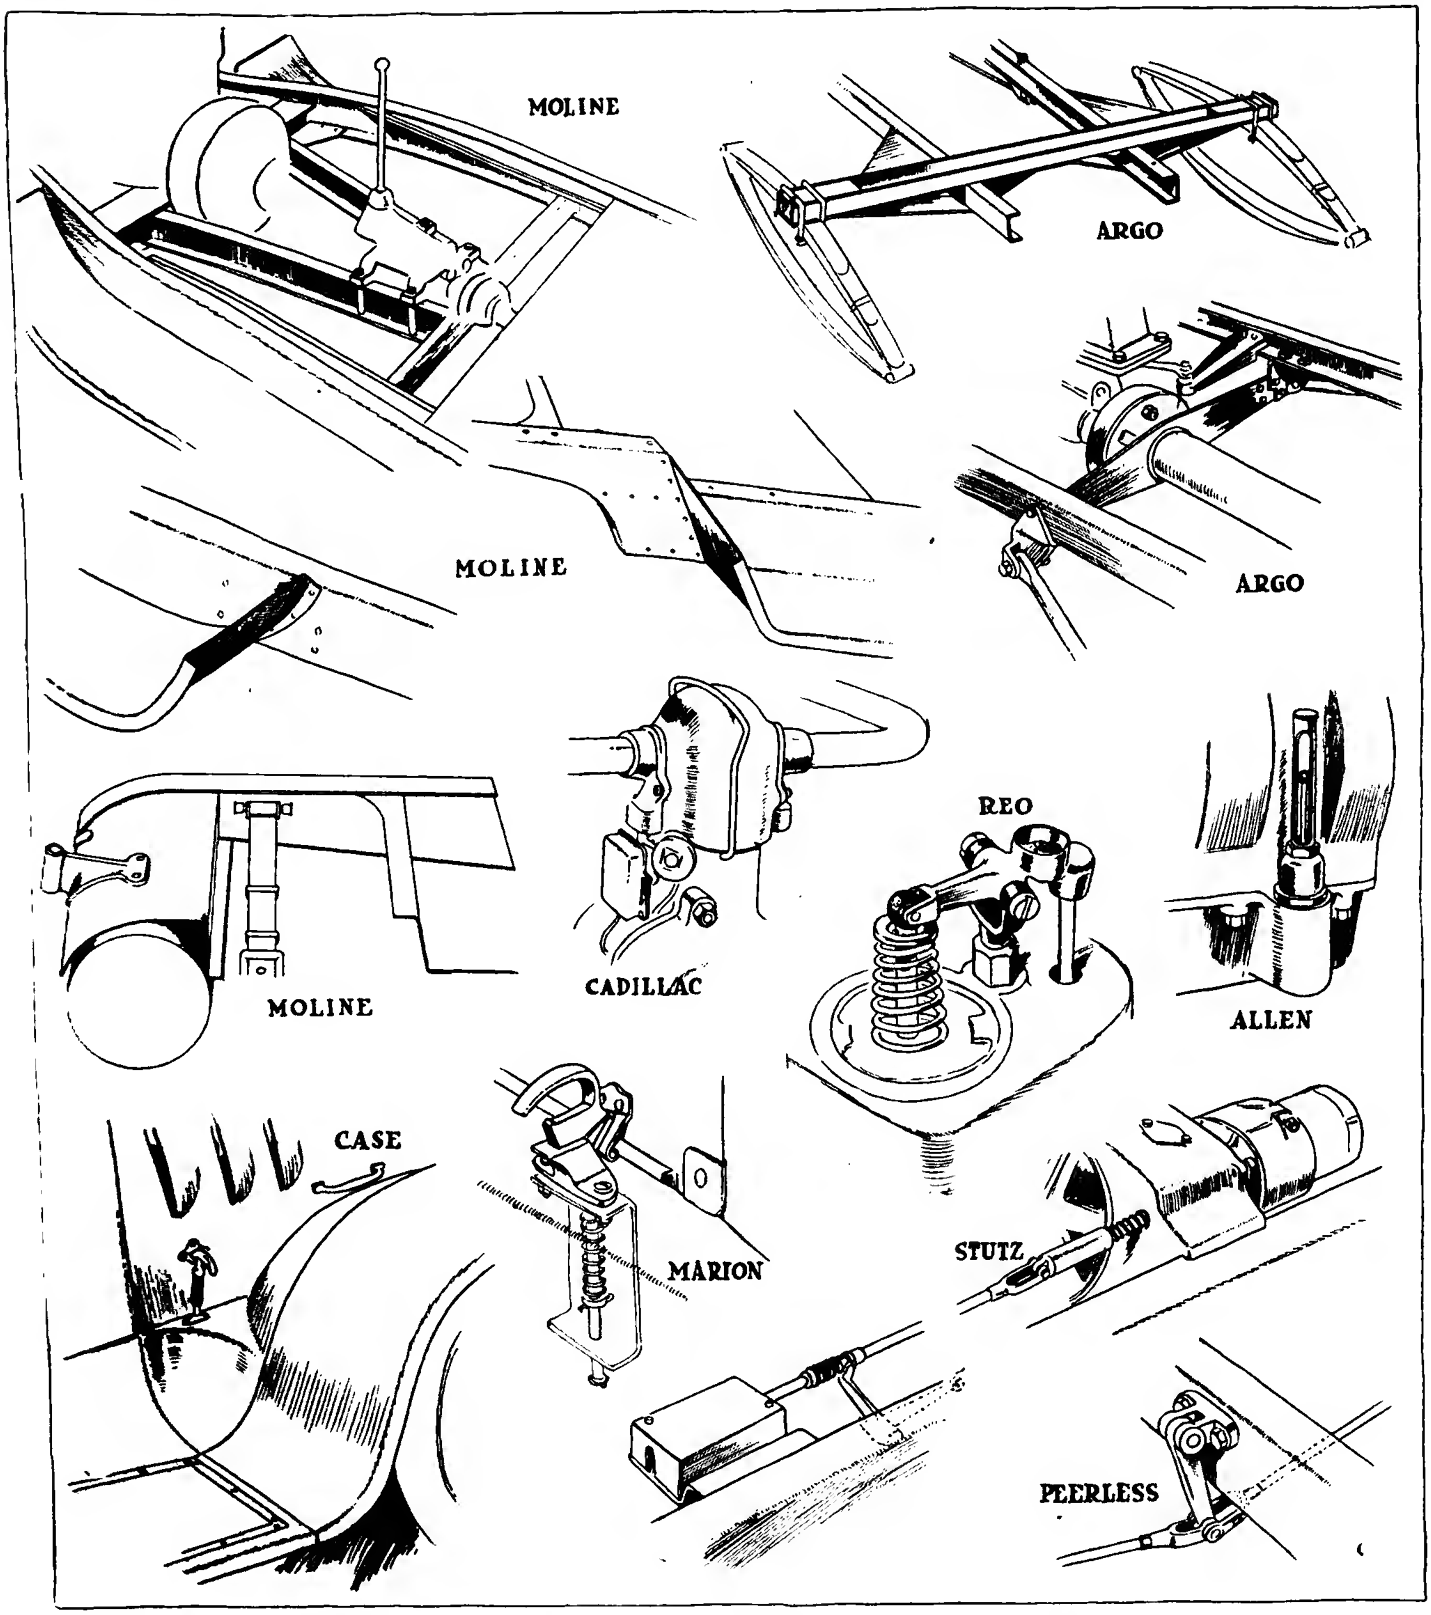
In connection with anti-rattling design the wide frames should be noted. These allow the body to be mounted directly over the side members of the frame and avoid the overhang which is frequently one of the causes of body squeak. The new Marmon car is a good example of this type of construction and the Hupmobile is also wide in the frame to take the body supports directly over the side members. Linings of woven fabric between the chassis and the body are also used to prevent the squeak which develops when the wood sill bears directly against the metallic frame structure.



BESIDES anti-rattle devices on brakework there are many different equalizing mechanisms to be studied. The Case has the equalizer beams mounted on the back of the gearbox, and takes advantage of this position to provide a convenient hand adjustment. Owen has a rather complicated, but efficient assembly on the countershaft. Empire was one of the first to use the rear axle location for the equalizers, and it may be noted that one pull rod and one stranded cable are used. Fiat uses an ingenious method for making the countershaft, the outer tube having a bridge piece to allow the lever from the rod to protrude. Maxwell makes use of the rear spring bracket to carry the brake countershafts, thus eliminating a pair of special brackets that otherwise would be necessary.



IT is customary now to find that a car has an adjustment for the brake and clutch pedals. The brake pedal usually can be set as to position by the forward end brake adjustment. These four sketches show different ways of giving adjustment for the clutch pedal. Paige threads the pedal piece itself and screws it into the end of the lever, and also goes to the trouble of providing an adjustment for the accelerator pedal, this being of a more simple nature. This is a very useful adjustment seldom thought of. Stutz uses a device fully explained by the cut, and this gives a very wide range of position to the pedal. Kline has a particularly neat adjustment, using a set screw and lock nut, the coil spring preventing the pedal from rattling. Dort has an original notion, and effects adjustability by providing a second hole at the bottom of the pedal, into which the brake-rod pin can be put.

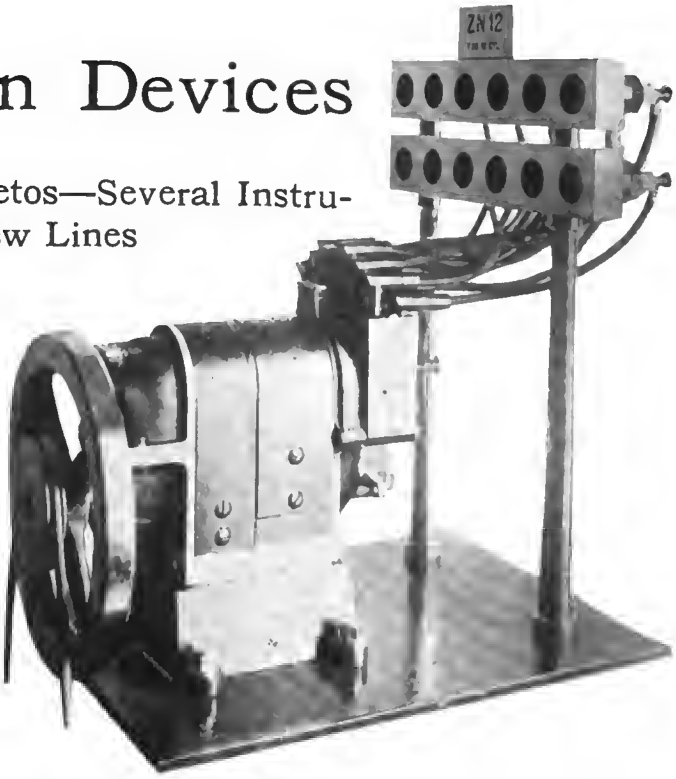


IN these sketches are shown two extremes of frame construction. The little Argo has the narrowest frame ever used, the side rails being parallel and a stout cross member is attached at either end, the full elliptic springs being clipped to the extremities of these cross rails. It is inexpensive, and simple and is quite effective for a small car, though it is difficult to see how such a system could be applied to anything much larger as the bending stresses are considerable. The other cuts show the details of the Moline-Knight frame, which is highly scientific and uses thin sheet steel in peculiar sections. In this the running board is used to provide stiffness to the side rails to which it is riveted.

Other details shown are a dirt excluding cover with a wire clip over the Cadillac distributor, the Allen oil gage, the fiber roller and felt oil pad on the Reo valve rocker, and the link which connects the Stutz starting motor to the switch. The Case sketch is of a strengthener between the fender and frame to prevent rattle, the Peerless shows a means of carrying the brake operation beneath a cross member of the frame and the Marion is of a new hood catch which, by sliding down the wedge shaped socket is self-locking.

Surprises in Ignition Devices

Two New Twelve-Cylinder Type Magnetos—Several Instruments for Eights—Some New Lines



Bosch Z-N 12 magneto for twelve-cylinder cars; new at show

TWELVE-CYLINDER magnetos are the high spots in the ignition exhibits at the show. The Bosch Magneto Co. is showing for the first time the Z-N 12 and also the Z-N 8, which are new designs particularly adapted for twelve- and eight-cylinder motors. The K-W Ignition Co. is also showing a twelve-cylinder magneto, while the Ericsson Magneto Co. is exhibiting a new line of automobile types.

While the Bosch magnetos are entirely new they do not radically depart from previous Bosch design. The distinguishing features are the offset pole pieces and the novel arrangement of the high-tension distributer bridges. The series for eights and twelves is known as the Z-N and it very closely parallels the N-U series in that the current is gathered on a slip ring in the rear of the instrument and carried forward by current bridges. On these instruments there is a double slip ring which in construction resembles the result which would be accomplished by placing two of the regular Bosch slip rings against each other.

Double Distributer Used

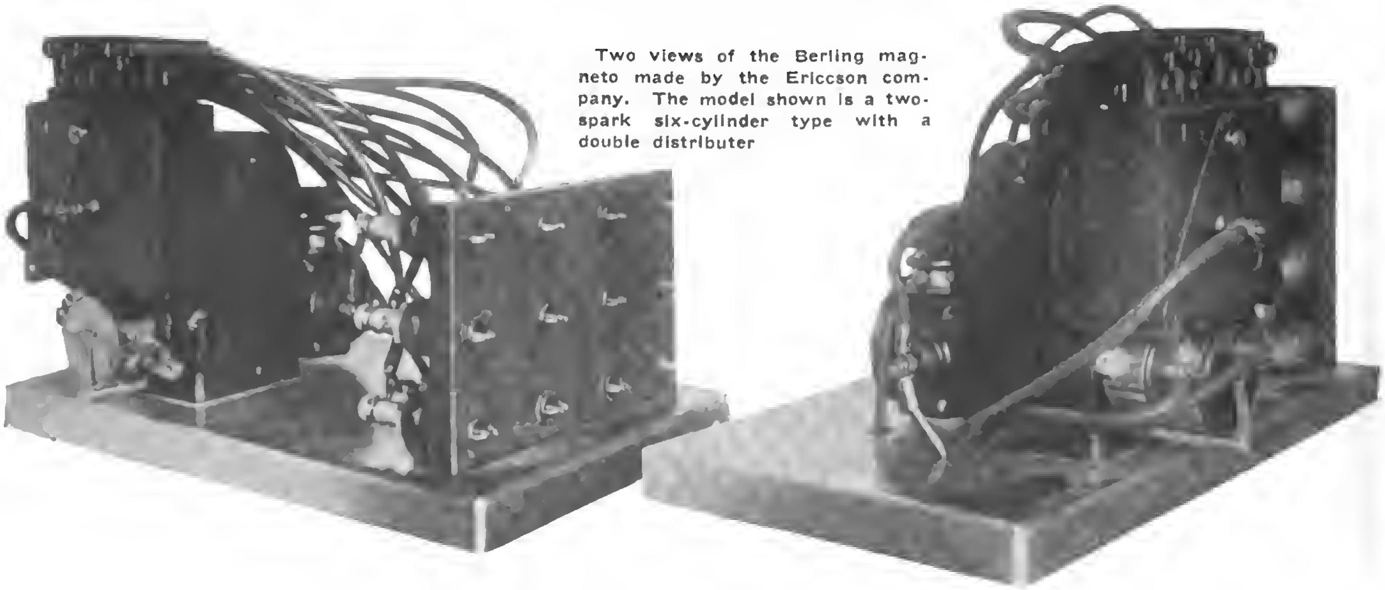
The distributer is double, as it has not been considered feasible to attempt to arrange the twelve distributer points around the circumference of one circle. Two distributer circles are used with the points so disposed that the current is taken alternately from each. In carrying the current from the lip rings to the distributer the forward unit in the slip ring is connected with the high-tension bridge which passes directly through the center of the magneto. The current from the rear slip ring is taken by a cable which passes out around the side of the magneto to the exterior distributer. Of course all this construction is within the magneto unit and is not visible on the exterior.

In order to take care of the current requirements of the twelve-cylinder magneto it is necessary that four sparks be produced in a revolution instead of two, as is ordinarily the case. This result has been accomplished by the use of offset fields, the pole pieces are so arranged that instead of two current waves being created in a revolution there are four, the field being in the form of a cross, so that at each quarter revolution the current attains its maximum. At first glance it might seem as if there was less field area than with the poles arranged to create two sparks in a revolution. This has been offset, however, by the use of higher magnets and the result is that although double the number of sparks are created the intensity of each individual spark is as great as in the previous Bosch models.

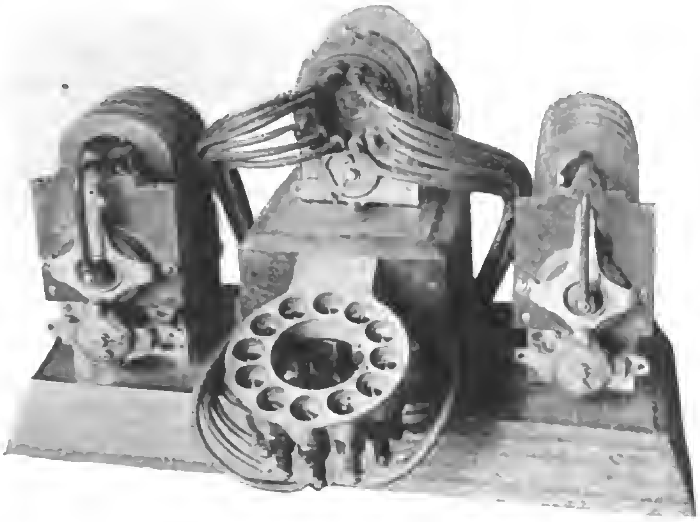
At the Bosch exhibit one of the twelve-cylinder models is shown mounted on a Packard twelve motor by means of a standard fitting which the Bosch company is marketing.

K-W Magneto for Twelves

The K-W magneto for twelves is constructed along the same lines as the larger machines put out by this concern. In producing the ignition requirements for the twelve-cylinder motor four sparks are given in a revolution, due to the use of cross poles. The twelve-cylinder magneto is driven at 1½ times crankshaft speed and the eight-cylinder magneto at engine speed. The visible distributer is one of the interesting points



Two views of the Berling magneto made by the Ericcson company. The model shown is a two-spark six-cylinder type with a double distributer



K-W magneto for twelve-cylinder motors. This is new at the show

of this magneto. The distributer box is provided with a mica cover whch permits of observing the action of the distributer while the magneto is running. This instrument is now manufactured for two-, three-, four-, six-, eight-, ten- and twelve-cylinder engines, and it is provided either with or without the K-W impulse starter as desired. This impulse starter operates on a set figure arrangement which is released when the engine is cranked, giving momentarily a high armature speed to create a good spark for starting.

Heinze Magnetos for Eights

Heinze magnetos are now made in eight-cylinder units under the model name of B-8. With these magnetos two ignition sparks are produced during each revolution of the armature. The eight-cylinder magneto does not vary from the regular Heinze product except in the number of distributer points. The magneto is featured by the round section magnets and the round armature. The object of using the circular construction is to permit of the minimum amount of wire length in the primary and secondary circuits in order to cut down internal resistance.

The Price company is showing a combined ignition, lighting and starting unit which promises to be of interest, as the unit not only includes the lighting outfit and generator parts but also the breaker mechanism, high-tension distributer, coil and condenser. These are combined in a compact unit which weighs comparatively little in consideration of the large number of functions taken care of. As the exhibits are not yet complete, due to the non-arrival of samples which are promised during the week, a complete technical description is not as yet available.

Auxiliary Ignition by Battery

The New York Coil Co., New York City, is showing a battery ignition system which is designed to cause any high-tension magneto to deliver a vibrating spark for starting.

The device consists of a low-tension vibrator coil which is in series with the battery and low-tension circuit of the magneto. The coil is a specially wound mechanically operated device, including a circuit breaker and condenser somewhat resembling a Master vibrator in principle. With this is supplied also a kick switch which when turned to the battery position places six dry cells in series with the vibrator and low-tension winding of the magneto. When the magneto is revolved, to the position where the breaker points on same separate, a rapidly made and broken battery circuit flows through the armature. This induces a vibrating spark in the secondary winding of the magneto and this spark is distributed to the proper cylinder by the regular distributer mechanism of the magneto.

Gives Magneto Advantages

When the switch is turned to the opposite side marked magneto, the magneto operates in the usual manner and is in no way connected to the battery. This gives all the advantages of high-tension magneto ignition.

As the switch is furnished separate, with wires attached, it may be located at the driver's side of dash allowing the vibrator mechanism to be installed on the engine side of the dash in any position or location most convenient.

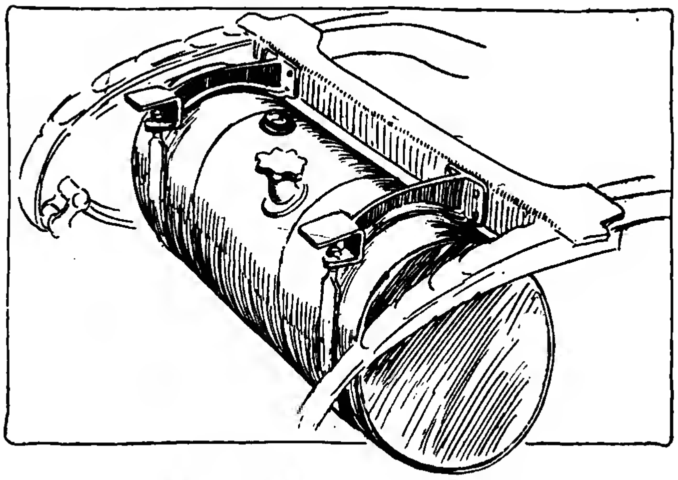
The price of the outfit is $8 and it is especially designed to fill the wants of those who desire easy starting in connection with single magneto ignition.

Circular Gasoline Tanks Increasingly Popular

WITH the coming of vacuum feed and the abolition of the cowl tank we find many low-priced cars with the tank at the rear of the chassis. The tank shaped to fit the frame must necessarily be a special product and costs much more to make than a plain cylindrical tank, while weight for weight the cylindrical pattern should be the stronger. Thus it is noticeable that many of the cars in the show have rear tanks of round section, clipped in stout brackets that are riveted to the end of the frame.

These brackets often serve as tire carriers also, so things are developing toward a sort of "tire and tank assembly" as a unit for frame attachment. If the coming of the round tank continues, and the use of tanks made by specialists increases, as seems likely, the situation offers an opportunity for standardizing work. Tanks at the end of the frame are always a little liable to damage and two or three standard diameters should meet all requirements.

Another advantage of the round tank, is the ease of removing it from the frame. This is a job that is seldom necessary, but when a car has run a whole season it is usually a good thing to clean out the tank so as to remove any accumulated dirt, rust or moisture, and so save the necessity for cleaning out the carbureter from time to time. Old cars are much more liable to suffer from dirt in the carbureter than are new ones, and this is largely because of the gradual deterioration of the inside surfaces of the tank. To clean out a tank efficiently it needs to be shaken thoroughly when partially filled with some cleansing substance and this is much more easily performed with the tank detached.



Marion tank and combined brackets

Valve Accessibility Improved Considerably

Many Factors In Problem

THE accessibility of valves is now less important because they are far less liable to give trouble than used to be the case, but accessibility of tappet adjustment becomes important in direct ratio with increase in motor efficiency. A slack tappet can seriously impair the power output of a motor of the high-speed type. Thus it is natural to find that makers of high-efficiency engines are doing all they can to render the adjustment of a tappet an easy job that can be performed by anyone.

To set a tappet needs usually, two spanners, one to hold the lock nut and the other to turn the tappet till it clears the valve by the right amount, so a fair amount of space in the vicinity of the valve stem is necessary.

Remove Accessories from Valve Side

There is a marked trend toward the removal of accessories from the valve side of the motor, so that removal of the valve inclosing cover lays bare the tappets and the spanners can be got to work without trouble. On the most modern sixes this quality can generally be found, developed to a high pitch of perfection. The V motors, with the exception of those with overhead valves which are the easiest of all to handle, are mostly open to criticism. In but few instances could any man other than an expert mechanic adjust *all* the tappets without first detaching some accessory or other. Usually it is easiest to remove the carbureter, but this generally comes away very easily with the intake manifold. There are some V engines, however, where even this step is not necessary.

The most powerful influence for good on vertical motors, either fours or sixes, has been the trend to the use of the offside mounting for the carbureter which leaves only the exhaust manifold on the valve side.

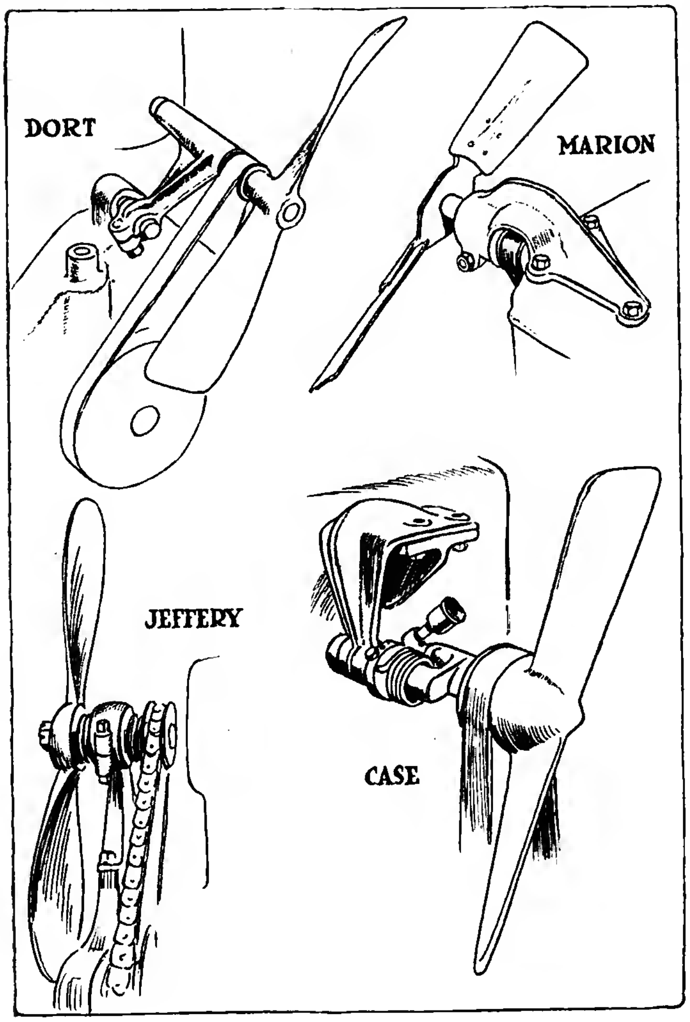
Electrical equipment is being mounted lower than before, and the generators are actually smaller, which reduces the interference that they may create. In very many cases the generator also is on the carbureter side which leaves the valve side completely clear.

The growing importance of keeping tappets well set up brings to the fore consideration of the possiblity of devising something better than the customary set screw and lock nut. It does require some skill to make the adjustment properly however much room may be given, and it ought to be pssible to find some self-locking device that wculd require only one nut to be turned. With overhead valves the simplest setting is obtainable by an adjustment on the fulcrum of the rocker and something similar should be discoverable for the L-head engines.

With Detachable Cylinder Heads

Ease of removing or grinding in the valves is greatest, usually, in detachable head motors and the only criticism that can be levelled against the latter is that some of them seem to have a needless number of nuts and studs. There is a good deal of difference in practice in this respect, but the minimum number that will serve is the best from the car owner's viewpoint.

It is noteworthy that few manufacturers consider it worth while to break the detachable head of a six-cylinder motor into two portions, the block head generally going with the block casting, but the owner is rather inclined to prefer handling the divided type as the ease of making a proper joint is certainly greater when the head does not cover more than three cylinders. Still, the block head is simpler, and it is also better from the point of view of proper water circulation and cooling, so the makers are probably right in their preference.



Two Blade Fans in Vogue

Many New Examples at Show

THE number of cars at the show with two bladed fans is quite remarkable, considering the comparative rarity of this type a year ago. A fan with two blades, properly made, will draw more air than any other type, but the cheap construction given by the pressed steel fan with four blades or more seemed till recently as though it would drive the more efficient pattern from the field.

The four examples of two-blade fans shown in the accompanying illustration have been picked at random as showing the difference in makers' ideas. The Dort design is a simple aluminum casting with thin blades and not a very steep pitch which remarks apply with equal force to the Jeffery fan. The Case, on the other hand, has very wide blades of an extremely steep pitch, and must be capable of creating a perfect gale of wind. The steel blade, which is practically as effective for automobile purposes and is less costly, is seen in two blade form on the Marion. It is not quite so pretty in appearance as the aluminum type, but the latter has no advantage on the score of weight.

How Many Horsepower to Run a Fan?

It would be interesting to make careful experiments as to the amount of power required to drive some of the bigger fans, at the high speeds to which they are geared to run. There are a few examples which, if the detail shape of the blades is correct to aeroplane practice, must easily need 4 or 5 hp. at a couple of thousand revolutions per minute.

S. A. E. Debates Important Matters

Annual General Meeting of the Society Elects Russell Huff President for 1916—Members to Discuss Papers on Magneto Versus Battery, on Steel and on Electrical Equipment—Many New Standards Adopted

WITHOUT doubt the great attraction of the S. A. E. meeting this year is the argument staged for Thursday, Jan. 6, when the opposing factions will take the floor in debate on the momentous questions arising from different ignition systems.

It is a triangular duel that has been arranged, between magneto, closed circuit battery and open circuit battery. The papers are given by Francis B. Hoyt for the magneto, Frank Conrad and Alexander Churchward figuring as protagonists of the battery.

Another paper of equally great importance, though more deeply scientific is by Dr. Unger on the sulphur content in steel.

Joseph Bijur will also deal with the electrical equipment of another sort, taking as his sphere the construction of lighting and starting apparatus, and Henry Schroeder will describe the design and manufacture of small electric lamps. Abstracts of these first four papers are to be found hereunder and the discussions of all the papers will be given fully in the next issue of THE AUTOMOBILE.

Standards Committee Active

During the whole of Monday, Jan 3, sundry of the standard divisions met and finally discussed their reports to be presented to the full Standards Committee meeting to be held next day. On Tuesday morning proceedings commenced in the Society's offices and the report of the day's work is given on page 21.

Ignition Papers Controversial

The discussion on the ignition question is sure to be very hot indeed, and to give a fair view of the leading off position it is better to review the three papers than to publish them in full previous to the discussion, which it is to be hoped will be successful in actually settling some part of this vexed question.

The Magneto Argument

Mr. Hoyt has prepared the longest of the three papers, and he gives a summary at the end which may be quoted.

For the best results the spark in an engine cylinder must occur at a time depending on the speed with which the gas can burn.

Spark advance, while necessary, is often (though inefficiently) used as a substitute for spark heat.

The unavoidable errors nearly always present in spark timing can be compensated for to a great extent by increasing the spark heat.

The open circuit battery system relies entirely on spark advance for meeting varying engine conditions.

In the closed circuit battery system the spark grows weaker as the speed increases, which is wrong.

The larger the spark the faster the flame spread and the greater the efficiency.

A prolonged spark is necessary for advanced positions owing to vapor variations in the cylinder.

The magneto spark, increasing in intensity with the speed, is directly suitable to the requirements of an engine.”

Russell Huff

Russell Huff, president-elect of the Society of Automobile Engineers, is chief engineer of Dodge Bros., which position he assumed Nov. 1, 1915. Previous to that date President Huff was connected with the engineering department of the Packard Motor Car Co. It was on June 25, 1900, that he associated himself with the Packard organization in the drafting department. In 1905 he became chief engineer of the Packard organization. In 1907 he joined the Society of Automobile Engineers and since that time has been one of the active members both in general policy work and also in committee work. He was vice-president in 1913. Previous to his active connection with the S. A. E. work, President Huff was lending his best efforts to the mechanical department of the Association of Licensed Automobile Manufacturers, which maintained an experimental and testing laboratory at Hartford, Conn. President Huff has several thoughts in mind for his terms as president, one being increasing the membership very materially; another is the encouragement of an engineering digest of American and foreign literature; and the third is devoting more attention to the finances of the society.

Battery Viewpoint Is Different

Such statements cannot go unanswered, but neither Mr. Conrad nor Mr. Churchward have made positive statements in their papers which can be used as answers to the accusations made by Mr. Hoyt. Both have tackled the subject from somewhat different angles. The former author states positively that the long enduring spark has no value, because directly the small body of gas surrounding the spark plug points has been burnt any continuance of sparking can have no effect upon the rest of the gas in the charge. He also states that a shortcoming of the magneto is that the voltage of the spark is limited, whereas the battery spark can be of any voltage desired.

Broadly the view taken by the two battery protagonists is that the remarkable success of the magneto compared with that of early battery systems lay in the superiority of magneto breaker mechanism. That to-day the battery systems have improved breakers till they equal or excell those of the magnetos. In other words that the battery ignition has been brought to perfection by following mechanical development rather than electrical.

Taking a quick impression from the

three papers a study of the many diagrams and photographs of sparks taken with elaborate scientific instruments suggests that the battery ignition spark can be made to do pretty much the same as the magneto spark except to last longer and longer as the speed increases. That there will be a very hot discussion goes without saying, and it is impossible to even guess what way the feeling of the meeting will trend. The three papers are each able expositions of different aspects of the electricity and the mechanics of ignition, yet they cannot all three be right in their conclusions. Perhaps the discussion will enable the balance to be struck, and if it does those who take part will have reason to be proud of having aided to settle the most burning question of the day.

Sulphur Content May Be Raised

Tests Show Open-Hearth Steel Little Affected by Reducing Sulphur Below 0.1 Per Cent.

By Dr. J. S. Unger*

THAT the sulphur content of basic open-hearth steels has been given a fictitious importance is the opinion of so great an authority as the author of this paper. It is Dr. Unger's contention that if sulphur is held down to 0.1 per cent that is low enough for all purposes for which basic open-hearth steel is commonly employed. To test his theory Dr. Unger had a series of steels prepared, containing various amounts of sulphur from 0.025 up to well over 0.2 per cent. These steels were manufactured in the ordinary way and from them many sorts of articles were made by ordinary processes, the idea being to not only test the strength of the steel as first made, but to test it after it was in the finished form. All sorts of things from sheet steel stove pipes to automobile crankshafts were made and in a fairly lengthy paper Dr. Unger tells what happened to the various steels in manufacture of the sample parts and in the testing machine afterward.

The results go to prove that the results are not noticeably improved in any way by cutting down the sulphur below 0.1 per cent. Below is the introduction to the paper which explains Dr. Unger's ideas, which was followed by an account of the detail adopted in making the steels and finally, a series of tests are quoted with their results. Of these, one table, characteristic of the whole, is given below.

Introduction to Paper

During the last fifteen years the proportional tonnages of steel manufactured by the Bessemer and open-hearth processes have undergone a great change. During 1900 about 65 per cent of the total tonnage of steel made was Bessemer and 34 per cent open-hearth. In 1914 about 26 per cent was Bessemer and 73 per cent open-hearth. Of the latter 94 per cent was made by the basic process.

As the low phosphorus ores became scarcer, higher phosphorus ores supplanted them. The latter produced a pig iron too high in phosphorus to be used in the acid Bessemer process; consequently the basic open-hearth process, with its attendant purification, grew rapidly.

Wherever Bessemer steel has been used, the sulphur content has varied from 0.050 to 0.080 per cent, or even higher, depending on whether the iron was used direct from the blast furnace or remelted in a cupola. Millions of tons of Bessemer steel, containing an average of 0.070 sulphur, have been used for almost every purpose. The greater part of such steel is still in service, giving an excellent account of itself, and furnishing us with the best possible evidence that steel may contain a reasonable amount of sulphur without being injured in quality.

With the advent of basic open hearth steel the consumer found that from 0.040 to 0.050 per cent sulphur, or about two-thirds that of the Bessemer, was the usual sulphur content of such steel. Believing that high sulphur always indicated that the steel was bad, he naturally insisted on the lower limit, or below 0.040 per cent sulphur in his steel.

Sulphur in steel, whether justly or unjustly, is in many cases held responsible for the bad working of steel. As a result the specifications covering the allowable amount of this element have been gradually lowered until in certain cases below 0.030 per cent is the limit demanded. It is very difficult to reach this limit by the basic open hearth process, and when reached there is a grave doubt in the minds of many whether the quality of the steel has not suffered by the excessive purification required to produce such results.

It became almost the universal practice when steel showed a tendency to work badly or become red short to make an analysis of the steel. If this analysis indicated that the steel had the proper or permissible amounts of the usual elements but happened to be a few thousandths of a per cent higher than the permissible amount of sulphur, the sulphur was held responsible for the trouble. Such decisions are made without considering other causes occurring in the manufacture of the steel; such as the heating and rolling and subsequent operations in working it up into a finished product.

The manufacture of steel in quantities of several tons at one time began when the Bessemer process was introduced about fifty years ago. Chemical analyses at that time were crude, or not made at all. Failures due to poor raw material or improper metallurgical treatment were common. Sulphur was largely blamed for such results, and a strong prejudice against it was established. This belief was handed down from one person to another. Rarely has it been questioned, nor have many efforts been made to establish the truth, until at the present time few are ready to believe that Sulphur up to a reasonable amount, say under 0.100 per cent, does not affect or at the most only slightly influences the working properties during manufacture, or the quality of the finished steel.

Effect of Low Sulphur on Steel

Some steel making processes have been brought forward which produce a steel lower in sulphur than the basic open-hearth process, but where the author has had an opportunity to compare such steel with open-hearth steel having the same physical properties, no difference could be detected in the surface produced or the hot working properties.

The subject of sulphur in steel has been studied by others. Results have been published in which soft steel and wrought

Carbon Content	Sulphur Content	Elastic Limit, Lb. Per Sq. In.	Tensile Strength, Lb. Per Sq. In.	Elongation in 2 In. Per Cent	Reduction of Area, Per Cent

*Extracts from a paper presented at the annual meeting of the S. A. E., Jan. 6. 1916.

iron containing 0.300 to 0.600 per cent sulphur have been successfully forged. The details are lacking, but it is my belief that such material would stand very little heating to a high temperature for forging without cracking or crumbling during the forging operation. I have in mind an investigator who has recently studied the effect of sulphur in different heat treatments of steel, with sulphur ranging from 0.032 to 0.157 per cent. Another studied its effect in rivet steel, containing from 0.042 to 0.105 per cent sulphur; a third in drop forgings containing from 0.028 to 0.190 per cent sulphur. Their results agree in this point: When other conditions are equal, no marked differences were observed in the working properties or in the quality of the finished material.

Headlight Glare Defined —New Standards

Recommendations of Spring Division and Resolution on Headlight Glare Adopted—Solid Tire Standards

NEW YORK CITY, Jan. 4—The standards committee of the S. A. E. met this morning to consider a large number of reports presented by different divisions. The reports accepted by the committee will be submitted to the general meeting of the society to-morrow. Foremost among the work of the day is the adoption of a resolution proffered by the electrical equipment division on the subject of headlight glare which reads as follows:

> *Wherever there is not sufficient light within the limits of the highway location clearly to reveal all persons, vehicles or substantial objects within said limits for a distance of at least 150 feet, the headlights of any motor vehicle in motion shall give sufficient light to reveal any person, vehicle or substantial object on the road straight ahead of such motor vehicle for a distance of at least 150 feet.*
>
> *The headlights shall be so arranged that no portion of the reflected beam of light, when measured 75 feet or more ahead of the lamps, shall be over 42 inches above the level surface on which the vehicle stands. Such headlights shall also give sufficient side illumination to indicate any person, vehicle or substantial object 10 feet to the side of said motor vehicle at a point 10 feet ahead of the lamps.*
>
> *The term "beam of light" as used in the above provision shall be construed as meaning the approximately parallel focalized rays gathered and projected by a reflector, lens or other device.*

The division further reported that it had had the subject under consideration for over two years and that almost every anti-glare device on the market had been examined. The report continues:

"It will be noted that the fundamental idea is the securing of adequate illumination, and the direction of the light in such a way as to render it unobjectionable to users of the highway. In view of the widespread approval which this provision in substantially its present form has received from legislators, municipal executives and safety organizations, and in view of the sound engineering foundation underlying it, the Division bespeaks for this provision the serious consideration of all interested in the securing of adequate and unobjectionable illumination."

Before the passing of the resolution there was a vigorous discussion in which several members of the committee voiced the opinion that the definition was not close enough. It was suggested that the actual spherical candle power of the light at 150 ft. ought to be stated and stress was laid upon the different degrees of visibility of different colored objects. The supporters of the resolution, however, answered this criticism effectively by pointing out that its object was to provide something easy to test, and simple to operate that might serve as a basis for the many different bodies who are just now trying to define headlight glare.

Another recommendation of this division adopted by the standards committee was in connection with the detail dimensions of insulated wires of different sorts intended to assist the manufacture and purchase of wiring suitable for automobile work. A third recommendation, also accepted was the following.

Location of Slots in Headlight Receptacles

"The Division recommends that the standard position of the slots in headlight bulb receptacles be so fixed that the anchor pins of the bulb when installed shall lie in a horizontal plane.

"Compliance with the above recommendation will improve very materially the situation so far as half-frosted or other partially opaqued bulbs are concerned. This may not result immediately in a definite disposition of the filament with respect to the anchor pins but it is hoped that the removal of this one variable will encourage the bulb-maker to bring about the best possible relation between those bulb elements involved in the proper direction and distribution of the light."

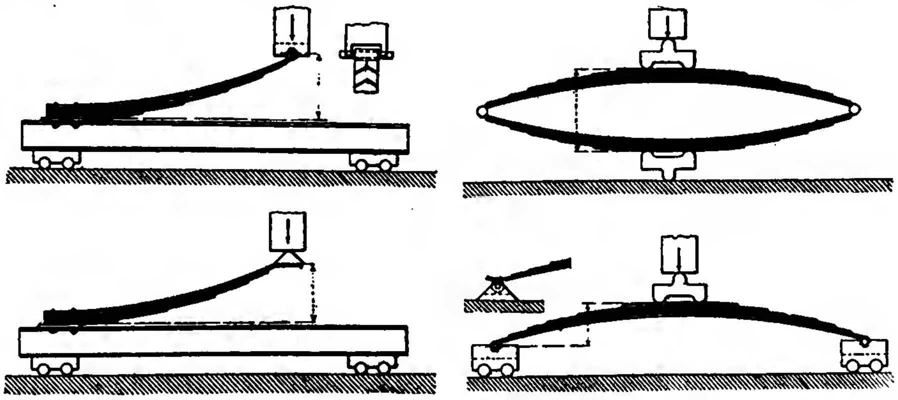
Iron and Steel Report Voluminous

The report of the Iron and Steel division of the standards committee deals entirely with details of testing of materials. It is proposed to substitute this fresh report for the whole of the "notes and instructions" appearing under the head "Carbon Steel" in the last published list of S. A. E. steel specifications.

A second portion deals with the details and dimensions of the standard test specimens and the object of both revisions is, in the main, so as to conform more closely to the practice of the Society For Testing Materials. The committee accepted the whole of the report without discussion and, since it is of considerable importance, the text is reproduced at the end of this account of the meeting.

New Solid Tire Standard

It is well known that for several months past an endeavor has been made to prove that two sizes of solid tires, namely 36 in. and 40 in. nominal, to fit on two standard S. A. E. wheels would be sufficient for all needs. But it has been ascertained that the demand for a 34-in. solid tire is so large



Diagrams of standard methods for spring testing for quarter-, semi- and elliptic springs that to neglect this size is impossible. Therefore the standards committee has adopted as S. A. E. standards the three sizes of 34 in., 36 in. and 40 in.

Also accepted for approval of the general meeting on Thursday is a new standard for the tires of industrial trucks, this specifying four sizes, 10 in., 16 in., 22 in. and 27 in. Both these matters are in the sphere of the truck standards division, and this body asked for a return to the use of ¼ in. felloe band for 4 in. section tires as this had proved adequate. The present standard calls for ⅜ in. This also the standards committee approved.

Pump Bases and License Tags

The subject of pump bases and brackets for license tags was the main theme of the report of the miscellaneous division. These standards were dealt with at the Chicago meeting and fully described in the report of that gathering. The only new standard to be added under this head is one for water hose as used in motor and radiator fitting. The table below shows the new standard as adopted by the committee.

The miscellaneous division reported that it was working on the matter of standard piston rings and hoped to be able to announce something definite before long.

Spring Tests Standardized

Another report accepted as printed was that of the springs division. This specifies methods for testing springs and lays down what shall be fair tests, specifying what the consumer may demand of the spring maker. The diagrams herewith are taken from this report and show the variety of test considered, and the report contains the fullest possible instructions for testing.

Other Business Done

Other divisions reported progress and indicated that the work of the standards committee is in a very healthy condition. First it was stated by Chairman K. W. Zimmerschied that the work in connection with the nomenclature of automobile parts was going forward, the assistance of many manufacturers and service men having been enlisted. The list of names for motor parts was complete and that for the remainder of the chassis in good shape, so that it is hoped a full set of names may soon be in fit state to present to the society.

The electric vehicle division reported as follows on the subject of speed and mileage ratings for electrics:

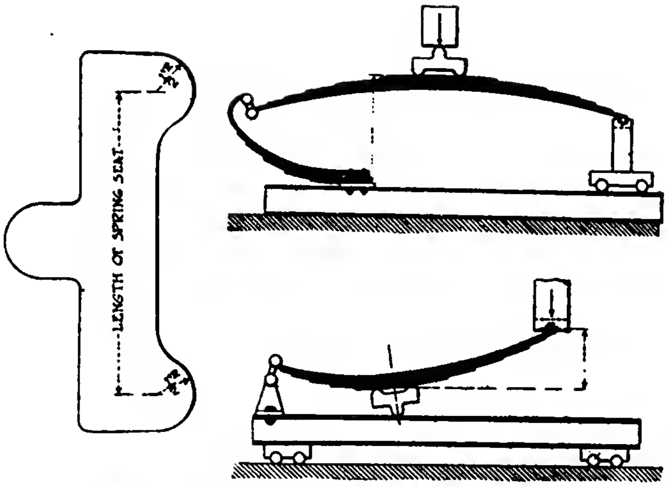
"Electric vehicle speed ratings shall be based on continuous operation with one-half load over hard, smooth and level roads or pavements at the actual average battery voltage.

"Electric vehicle mileage ratings shall be based on a continuous run at the S. A. E. rated speed with one-half load over hard, smooth and level roads or pavements.

Table I—Sizes of Hose-Clamps and Hose-Fittings

Inside Hose Diameter	Outside Diameter of Hose and Extended Inside Diameter of Clamps: Single-ply	Two-ply	Three-ply	Four-ply	Length of Fitting for Lap of Hose
3/16	7/16	½	9/16	⅝	1
¼	½	9/16	⅝	11/16	1
5/16	9/16	⅝	11/16	¾	1
⅜	⅝	11/16	¾	13/16	1
½	¾	13/16	⅞	15/16	1
¾	1	1 1/16	1⅛	1 3/16	1
1	1¼	1 5/16	1⅜	1 7/16	1¼
1¼	1½	1 9/16	1⅝	1 11/16	1¼
1½	1¾	1 13/16	1⅞	1 15/16	1¼
1¾	2	2 1/16	2⅛	2 3/16	1¼
2	2¼	2 5/16	2⅜	2 7/16	1¼
2¼	2½	2 9/16	2⅝	2 11/16	1¼
2½	2¾	2 13/16	2⅞	2 15/16	1½
3	3¼	3 5/16	3⅜	3 7/16	1½

Limits on inside diameter of hose ± 1/64. Limits on thickness of hose (not measured at lap) ± 1/64. All dimensions in inches.



Three-quarter and cantilever test and pressure block

"The above recommendation covering speed ratings has been previously submitted several times and approved by the Standards Committee. The recommendation submitted on electric vehicle mileage ratings has been modified materially from that previously submitted and referred back to the division of the society. Both definitions are in the simplest possible form, but it was found impossible to secure any unanimity of opinion among the vehicle manufacturers.

"This report has been submitted for consideration to ten members of the Electric Vehicle Division, which consists of nineteen members (including chairman of the Standards Committee), of whom ten have voted affirmatively, none negatively and none have refrained from voting."

The engine and transmission division reported progress with the collection of data on motor performance characteristics. They said that there had been encouraging results of inquiry as to the possibility of standardizing poppet valves in some sizes, hand starting cranks and V belts for fans. They stated, however, that they had found the suggested standard base for water pump mounting would be impracticable and disadvantageous.

A report from the research division, including a suggested form for testing cars for gasoline economy, was discussed and will be brought forward again at some future date, and brief progress reports were also put in by the chairman of the foreign co-operation division and the lock washer division.

Proposed Eighth Report of Iron and Steel Division

Revision of "Notes and Instructions"

IT is recommended that the text of the seventh report of the iron and steel division be revised by deleting all that occurs on page 160 of the June, 1915, Bulletin, before the title, Carbon Steels, and inserting the following:

Regarding Specifications, and Notes and Instructions

The notes and instructions following the specifications given below are not to be considered in any way a part of these specifications. They are added solely for the information of the user of the steels and the guidance of the purchaser in the selection of proper materials for his different purposes. They should not be incorporated in the specifications when ordering steel, except under such conditions as are noted in the body of the specifications themselves.

The compositions listed below include practically all the steel materials which the division believes are necessary for the production of the great majority of automobile parts, in grades which have been found commercially available and technically adequate to perform the service encountered in these parts. In cases where very special duty or exceptional quality is demanded, grades containing less phosphorus and sulphur and narrower ranges of carbon and manganese are available, but these special grades should be made the subject of special agreement between buyer and seller.

Specifications for Automobile Steels

Basis of Purchase

1. Automobile steels shall be purchased on the basis of the requirements as to chemical compositions specified in sections 5, 6 and 7. It is not recommended that tension and bend tests shall be specified for the material as shipped, except when physical requirements are specified. When steel is bought on physical properties, requirements as to carbon shall be omitted.

Steel Castings

2. The standard specification No. 1235 for steel castings, adopted by the Society of Automobile Engineers, shall cover the purchase of automobile steel castings.

Manufacture

Process

3. The steels shall be made by the Bessemer, open-hearth, crucible, electric, or any other process approved or specified by the purchaser.

Discard

4. A sufficient discard shall be made from each ingot to secure freedom from injurious piping and undue segregation.

Chemical Properties and Tests

5. The steel shall conform to the requirements as to chemical composition specified in the appended lists of carbon, nickel, nickel-chromium, chromium, chromium-vanadium, and silico-manganese steel.

Ladle Analyses

6. An analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt, a copy of which shall be given to the purchaser or his representative. This analysis shall conform to the requirements specified in the table of compositions. Drillings for analysis shall be taken not less than ¼ in. beneath the surface of the test ingot and in as sound metal as possible.

Check Analyses

7. (a) Unless otherwise specified, specimens from the original product shall be submitted for sampling by the chemical laboratory. Where cuttings are acceptable, these must be taken dry, must be thin and small, free from foreign matter and discoloration.

(b) Analyses may be made by the purchaser and shall conform to the requirements specified in the tables.

(c) Drillings for analyses of bars, billets or other regular shapes shall be taken parallel to the axis, at any point midway between the center and surface.

(d) Drillings for analyses may be taken from broken tension or bend test specimens, if physical requirements are specified.

(e) Drillings or cuttings for analyses of irregularly shaped pieces for which no physical requirements are specified, shall be taken from both the thickest and thinnest sections.

(f) Wire, tubing, sheets and rods less than 1¼ in. thick shall be sampled through or across the entire section.

(g) Surface drillings shall be discarded.

Physical Properties and Tests

Physical Properties

8. If physical requirements are specified, the following sections (9 to 13) shall form a part of the modified specifications.

9. The yield point, where specified, shall be determined by the drop of the beam of the testing machine.

10. The elastic limit, where specified, shall be determined by means of an extensometer.

11. The bend test shall be made cold.

12. (a) Tension and bend test specimens shall be taken from the rolled or forged material; except that in the case of irregularly shaped forgings, they may be taken from a full-size prolongation. Specimens shall not be annealed or otherwise treated, except as specified in paragraph (b).

(b) Tension or bend test specimens for material which is to be annealed or otherwise treated before use shall be cut, for rolled material, from properly annealed or similarly treated short lengths of the full section of the piece, and for forged material from the treated forgings.

(Continued on page 49)

New Six-Cylinder Lozier for $1,875

Larger Six Price $475 Lower—Four-Cylinder Model Now Only $1,595—New Six Motor 3½ by 5¼

NEW YORK CITY, Jan. 4—Lozier show announcements include the introduction of a new seven-passenger six to sell at $1,875, the reduction of the larger six from $3,250 to $2,775, and the reduction of the four from $2,100 to $1,595.

The new model is rated at 50 hp. and is equipped with a 3½ by 5¼ in. L-head block motor with the crankcase integral with the upper half of the motor. Starting, lighting and ignition are by a two-unit Gray & Davis system, and a Stewart vacuum feed system is used. The crankshaft is mounted on three bearings; crank, cam and connecting-rod bearings are nickel babbitt. The timing gears are helical and the camshaft is drop-forged. Cooling is by centrifugal pump. The multiple-disk clutch and three-speed gearset are in unit with the motor. Semi-elliptic springs are used in front and platform in the rear, and the rear axle is a floating with spiral bevel drive. The wheelbase is 120 in. and tires are 36 by 4½.

The new Lozier six-cylinder car for $1,875

Convertible and Permanent Touring Tops Highly Developed

Removable Glass Sides, Permanent Top Designs and Quickly Demountable Convertible Types Give All-Season Service and Provide Two Cars for the Price of One

Left—Permanent top design which allows of clear opening all the way around, giving the same results as the summer touring top except that it cannot be lowered

Right — Small roadster with convertible coupé top which can be placed on the roadster body by removing the summer top. This gives an ideal all-year-around design suitable for any kind of weather and makes a good physician's car

WINTER and summer have different sets of conditions which must be met by the body manufacturer, and it has been general practice for the owner of a high-priced chassis to have at least two bodies which can be mounted upon the chassis to provide against these requirements.

To bring the winter and summer body arrangement into the reach of the average car owner has been a feat which it would have been impossible to accomplish without the convertible body idea. Inaugurated at the show a year ago, the convertible touring car-sedan idea has spread rapidly and now many of the manufacturers in the field of cars selling for anywhere between $500 and $2,000 are providing bodies which have a removable top that can be put away for the summer, leaving the car in the same form as the ordinary touring design. Some of the interesting types of these cars which are now on exhibition are shown by Kissel, Hupmobile, Briscoe, Saxon, Marion, Empire and Dodge. There are others also who are manufacturing bodies of this type and all claim that the demand this season for the convertible design is up to their greatest expectations.

When the Winter body is in place the car resembles a high grade sedan; it is comfortable in the coldest of weather and the glass area is so large that the view of the occupants is not cut off to any appreciable extent. With the regulation top and side curtains the car cannot be kept as warm and, owing to the necessity for providing a large amount of cloth or other fabric between the windows in the side curtains, the view is not very good when these side curtains are in place. The convertible design provides a car with practically all glass sides, and one which if desired could be toured in with perfect comfort during the summer months.

An Optional Body Type

With the winter top removed the ordinary touring body is left. The summer top is put in position and the summer windshield put into place. To all intents and purposes this leaves the ordinary stock touring car, which does not differ in any respect from the car which the purchaser would have possessed if he had not purchased the convertible design.

In fitting these tops to the touring body the top irons, which ordinarily hold the summer top in position, act as the main supports. The touring bodies are so shaped that they conform exactly to the line of the removable sedan top, and when the latter is in position it should only be possible to detect the line of juncture between the convertible top and body by very close inspection.

The sedan effect of the convertible body is carried out by having the glass front a unit with the top, the supports for the ordinary summer windshield acting as the forward supports for the convertible sedan body when it is in place, so that in fitting the closed top the windshield and summer top are first removed and then the top is slipped down into the fastenings, which are made rigid enough to clamp the closed top tightly into place.

Roadsters also Fitted

The use of the all-season top is not confined to the touring cars. There are many two-passenger roadsters which are now provided with this extra fitting if so desired. The prices for these convertible bodies run as low as $455, at which price the Saxon is furnishing a two-passenger car fully equipped with a convertible design known as the all-winter top. This top is easily removed and really transforms the roadster into a coupelet. The price of $455 includes both tops, the standard roadster top being a part of the regular equipment whether the all-winter design is purchased or not. For physicians, salesmen, collectors and others who are compelled to be outdoors in all kinds of weather a car of this type should be ideal, and it is a fact that exhibitors at the Palace show have found that the listing of bodies of this type noticeably increase their sales.

Tops for All Seasons in Vogue

There is a growing class of motorists that desires to travel with a top on the car both winter and summer. To suit these the permanent top design, known as the touring-sedan, is proving to be very popular. There are glass sides on this type of car which are lowered directly into the sides of the body when it is desired to have a top which in general appearance conforms quite closely to the up-to-date one-person design. This top does not take away from the side view any more than does the ordinary summer touring top, but owing to the fact that it is permanent and no provision need be made for raising or lowering it, it is rigid and at the same time is lighter, through the elimination of the top bows.

When the glass sides are up on a design of this kind a complete sedan is provided which is just as windproof and weatherproof in every particular as the permanent sedan with the added advantage of the fact that the windows can be lowered in a few seconds, providing the open air touring body much desired during the summer months. The windshield of the cars of this class are such that on the road it would be difficult to distinguish a touring-sedan from the ordinary touring car with the top up.

Permanent Tops Are Popular

Another feature of the touring-sedan which makes it somewhat more luxurious than the ordinary touring car with the top up is that the sedan-top can be lined with upholstery that matches the interior of the body. It is also possible to provide electric lights in the upper rear corners of the body so that when the glass sides are up all the luxury of the full-town body is provided.

One of the points brought up in connection with the convertible designs is that the paint work of the winter top is apt to be bright and new while the lower part of the body has lost its bright finish, due to continuous use. In order to overcome this objection the convertible tops are given a dull black finish, much on the order of black leather. This black color blends very well with bodies which have lost their original paint lustre.

In making the convertible top absolutely waterproof it is necessary to take great care in the connecting joint lines between the touring body and the removable upper section. Rubber insert washers, which act as continuous weatherstrips, are placed around the entire top and also around the windows to prevent leakage. The irons for the summer top and for the windshield are made heavier than ordinarily for the purpose of taking the added weight due to the use of the convertible top.

A suggestion which has been made in connection with the use of the closed top on the convertible body is that it permits of the employment of a Victoria top for summer if so desired. This is a fine appearing top which acts admirably as a sunshade and at the same time permits a maximum view range from the tonneau seat. It is, of course, not a bad-weather top, but since the convertible design is so readily fitted in case of impending bad weather the Victoria top in connection with it furnishes an ideal combination.

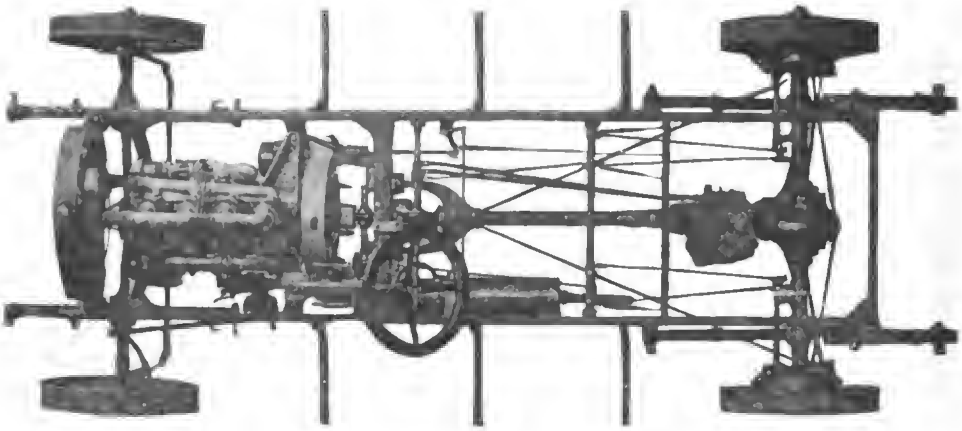
Convertible roadster coupé which gives a luxurious town body for winter or city use and an open roadster for summer work when it is desired to tour without a top. The summer top and windshield are fitted to this body when the coupé is removed

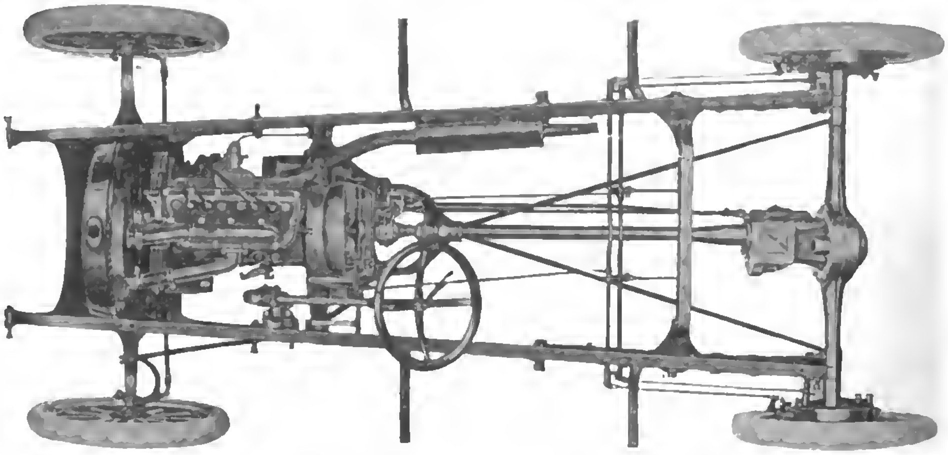
Lower—Quickly removable top which converts the typical open-roadster design into a convenient coupé with broadly glassed sides which do not interrupt the view as is even the case with the summer top with side curtains in position

Chassis Simplified for 1916

Elimination of Links, Rods and Arms Makes a Quieter Design of Greater Accessibility

By J. Edward Schipper





Contrasting the old and new Overlands, the relative simplicity of the 1916 car becomes apparent

ALL the tendency toward simple motor exterior and unit construction would be incomplete unless the same trend could be traced back through the chassis design. In the development of the car simplification has been the keynote, and giant strides have been made in this direction since 1914. In fact, it may be said that up to that year development had been more in the line of increased mechancial efficiency than in simplification of detail. In order to attain better mechanical results more detail was added than taken away, and the result was that the chassis of 1914 probably reached the pinnacle in number of parts. Since that time, every tendency has been toward securing the same results with fewer parts, and this in turn has made the car lighter and given a better vehicle because this lightness is such an important factor in performance.

Unit Powerplant a Factor

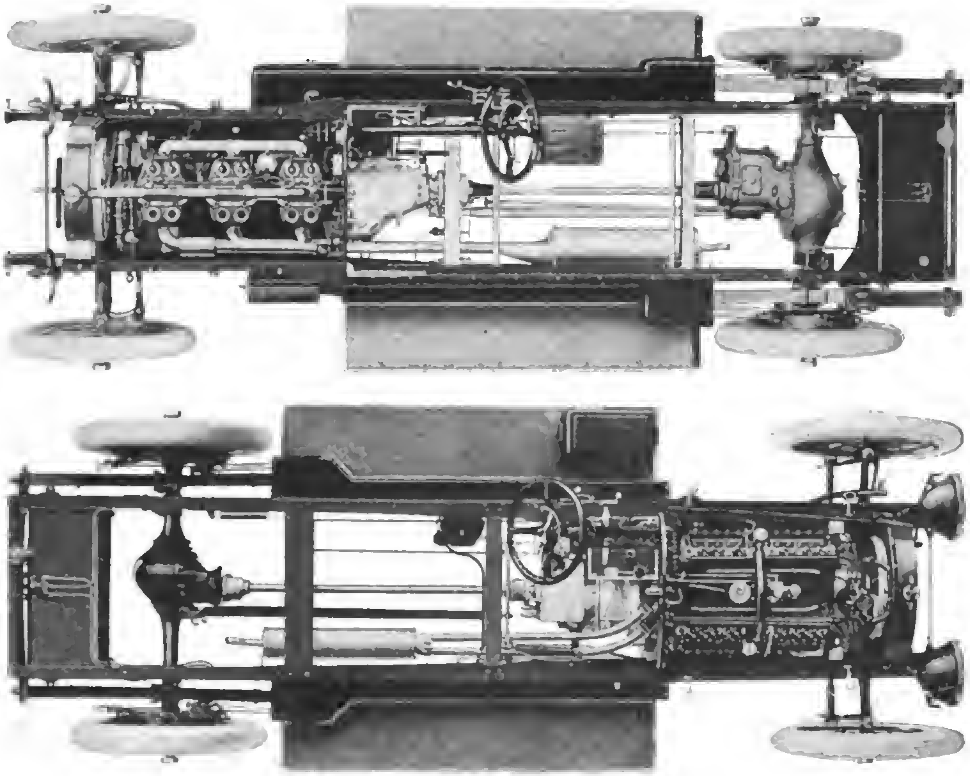
The first big step toward clearing the chassis lines and eliminating surplus parts came with the development of the unit powerplant. This method of construction immediately obviated the necessity for a large number of links and bars which on a plan view of the chassis make a striking difference. It must be remembered that every long link and every joint is a potential source of noise which may either develop into the rattle of looseness or the squeak due to dry rubbing contact. It is also a barrier in the way of accessibility and it is another part which requires attention from either the maker or repairman when he is working about the car. Simplification and accessibility go hand in hand. It is impossible to find an engineering job which is accessible that is not simple.

Illustrated on these pages are some good examples of where block casting and unit powerplant have had a sharp influence on the simplicity of the ultimate design. Referring to these it will be seen that the Packard twelve, for instance, is simpler than the Packard six as far as the entire chassis layout is concerned. The Cadillac eight is simpler than the four-cylinder model in chassis detail, in spite of the fact that it has double the number of cylinders, and the Overland model 75 for 1916 is a far more simple job than the Overland model for 1913. These are only a few examples selected at random, but they serve to show that the tendency toward simplification is not confined to the lower-priced or higher-priced cars, but covers the entire field.

The tendency away from the amidship gearbox in favor of the unit powerplant design in which crankcase, clutch housing and gearbox are all one compact unit, means far more than merely a change in position of the gearbox. In the first place it has meant the elimination of at least one cross member of the frame, this being the pedal and lever shaft which was frequently carried across the chassis just forward of the gearbox. It has eliminated, in many instances, a universal joint which was placed between the clutch and gearset in order to take any alignment variations in the drive and, most valuable of all, it has eliminated the connecting-rods between the gearshift gate and the gearbox.

Center Control Cuts Parts

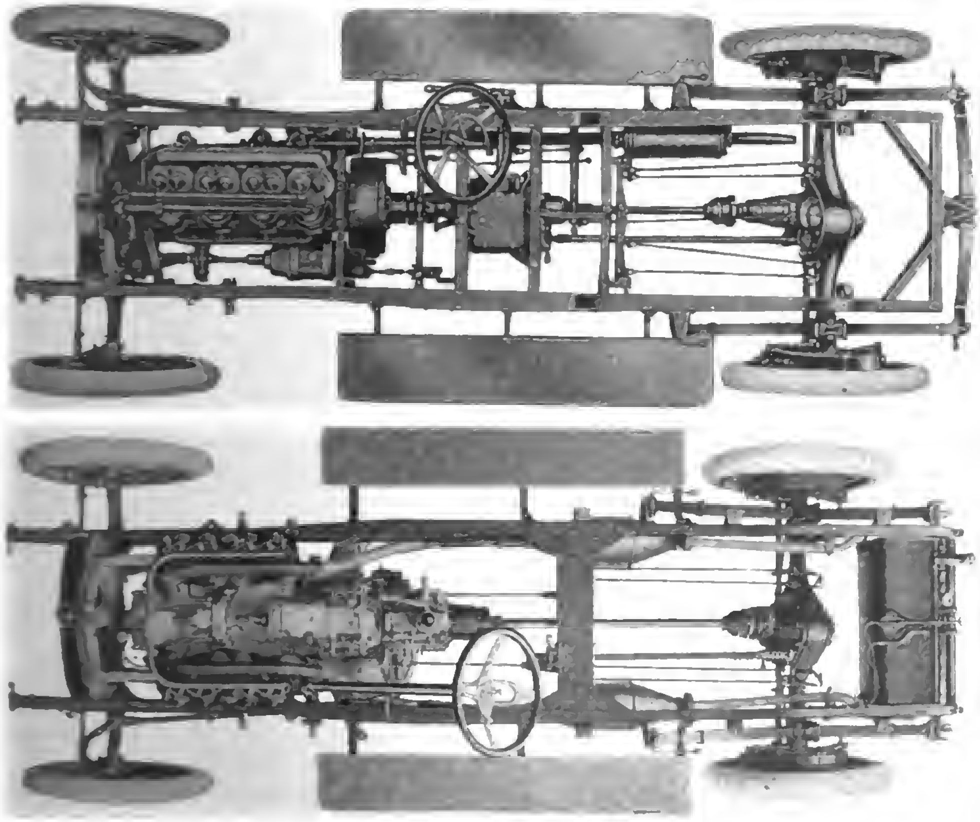
When the unit powerplant was developed it fortunately came at a time when the trend was all in favor of center control. These two features of design blend admirably. The unit gearbox is in such a position that the gear change lever can be mounted directly on the cover plate of the gearbox allowing the bottom part of the rod to extend downward and to act directly on the shifter collars. The result is that there need be no interconnection between the shifter lever and the gearset, since the shifter rod itself can act directly on the gearbox mechanism. This eliminates five or six exterior parts which were exposed to grit and dirt. It also eliminates certain parts which in connection with the gearshift lever, were outside the gearbox and in other positions were inside. These parts had to be lubricated as they had a sliding motion in the gearcase and the result was that a large amount of dirt and grit were carried into the gearbox and became a factor which tended toward shorter life of the gears.



Above—The Packard of 1913, and below, that of the present year. Observe the simplification resulting from adopting the unit powerplant

The up-to-date gearbox with its compact housing is gritproof. Furthermore, by the absence of disadvantageous linkage the throw of the gearshifter lever is considerably shorter, the gearbox itself being of smaller overall length, due to better design and closer spacing of the bearings; giving a relatively stiffer shaft owing to the shorter span between bearings.

Eliminating the rod connections between the shifter lever and the gearbox when it is in the amidship or rear axle position has not been the only means of clearing up the masses of linkage from the chassis structure. Brake connections have afforded an opportunity for the engineer to display his ingenuity as well as in the gearshifter mechanism. Taking an average 1914 chassis there were eight parts necessary to carry the motion of the emergency lever back to the rear brake shaft. These were first, a sleeve on the cross shaft at the center of the chassis; second, a bell crank lever mounted on the sleeve; third, another bell crank lever mounted on another cross shaft; fourth, a sleeve on this cross shaft; fifth, another rod leading back to a bell crank lever on the shaft to the brake assembly; sixth, a bell crank lever on this shaft; seventh, a bearing sleeve on this shaft, and eighth, a bell crank lever to the contracting mechanism. This number has been reduced by about one-half in most of the up-to-date chassis, the result being accomplished by the use of one straight rod from the brake lever or pedal directly back to the rear brake shaft. If it is necessary to increase the leverage between the lever or pedal and the applying point of the brake, this is done by having one intermediate shaft with the desired reduction linkage.



Above—The Cadillac of 1913, and below, the eight-cylinder Cadillac. Notice the much cleaner nature of the latter

Hotchkiss Drive

Hotchkiss drive in which both propulsion and torque are taken through the rear springs has eliminated the use of radius rods, torque tubes, torque arms and the various spring connections on a large number of chassis for 1916. Hotchkiss drive is used on nearly 50 per cent of American cars, and this means that nearly half the American makes are not complicated by miscellaneous bars, rods and springs fitted for the purpose of taking driving and torque stresses.

On the rear axle the cable truss reinforcement which, with its turnbuckle adjustment was a notable feature on cars of 1914 and 1915, is noticeably absent on the 191[illegible] cars.

Accessory Improvements Reflect Car Design

Simplification and Refinement Make Devices More Efficient While Attention to Detail and Mounting Enables the Car Designer and Owner to Blend Them Into Car Lines

TAKEN broadly, the accessory field shows that there has been a marked amount of progress in detail design during the past year. Each individual accessory has a trend toward simplification and efficiency and also toward the important matter of having the accessory blend with the car. The tendency in automobile design is to maintain a clean exterior and, hence, it is found that accessories are being designed to carry out harmoniously this idea of simple appearance. In accessories which do not fit on the car, but are of use in taking care of it, there have been improvements which tend to make the devices in question quicker in action and simpler of manipulation in the hands of the car owner. With these lines of improvement have come reductions in price, so that it can be generally said that automobile accessories are better than they were a year ago and lower in price.

Follow Car Trends

Some of the trends in accessory design have been direct reflections of the tendencies in the design of the complete vehicle. For instance, the higher speed motors have called for more efficient ignition apparatus to meet the demand of more sparks per unit of time and hotter sparks at lower speed to correspond with the ability of the up-to-date car to travel at the lowest possible speed on high gear. These two developments lead specifically to the fact that ignition apparatus on the whole this year is capable of producing a hotter ignition flame at the lowest possible rotative speeds and is also able to furnish ample ignition and positive firing in every cylinder up to speeds of as high as 3500 r.p.m.

The two developments of higher rotative maximum speed and minimum high gear traveling speed have also put the two most difficult demands possible on the carbureter, and the result is that it will be generally found that the carbureter of 1916 is capable of furnishing a better mixture at minimum speed, better acceleration throughout the speed range, and, finally, consistent carburetion at the maximum speeds. These results have been accomplished both through the better design of the gas handling features of the motor and through the efforts of the carbureter manufacturer.

The same story of better efficiency and better co-ordination between car and accessories spreads throughout the entire gamut of accessories. It is found in electric lighting and starting units, steering gears, horns, shock absorbers, tire pumps, bodies and every other accessory development, as well as in the ignition and carburetion field.

Magnetos for Twelves

The automobile show this year discloses the first efforts of the magneto manufacturer to meet the demand of the twelve-cylinder motor. The Splitdorf Dixie type, which has been in use now for a few months, ushered the magneto into the new field. At the show there are two others, the Bosch and the K-W. The new magnetos do not depart radically from previous magneto design in meeting the necessity for twelve-cylinder ignition, but there has been one important change which inaugurates a new epoch in magneto manufacture. This is the use of the offset poles in which the fields are so arranged that instead of generating two sparks for the revolution of the armature shaft, four sparks are produced. The result of this is that the magneto does not have to be driven at abnormal speeds to produce the ignition for twelve-cylinder motors. In a magneto producing but two sparks to a revolution it would be necessary to gear the magneto to three times crankshaft speed. It can be readily perceived that, with an engine rotating at 3000 r.p.m., it would be necessary in the case of a twelve to have the magneto rotating at 9000 r.p.m. This is impractical. With the offset pole and four sparks per revolution, the 1½ to 1 ratio solves the problem. Bosch has introduced this in its new type and the K-W likewise uses it.

Battery Ignition Progress

Battery ignition design has been quite well developed during the year and the show does not bring forth any surprises. Perhaps the one new feature is the Price combined lighting and ignition unit in which the generator casing houses the entire ignition unit, including breaker mechanism, distributer, coil, and condenser. Interesting applications of all the systems will be noted on the cars exhibited. The outstanding feature is that the electric system now is a built-in portion of the power plant.

Few New Carbureters

There are few new carbureters at the show, although the exhibit is entirely representative of the carbureter industry in that nearly all of the large producers, with the possible exception of Holley, are present. There are very creditable exhibits by such firms as Wheeler & Schebler, Stromberg, Rayfield, Zenith, Kingston, Carter, Stewart, Master and others.

The Stromberg is exhibiting its new model in which the auxiliary air valve is eliminated and in which the basic principle is atmospheric control as based on the Ahara patents. In this carbureter there is not a single moving part with the exception of the throttle. The design has a gasoline well for rapid acceleration. In Stromberg Model K acceleration is cared for by a secondary nozzle in which is a metering pin controlled by the auxiliary air valve.

Wheeler & Schebler shows its new Model T with the metering pin controlled by the auxiliary air valve instead of by the throttle. Rayfield has its improved model in which an acceleration feature is combined with the auxiliary air valve whereby the quick opening of the valve injects by pumping action gasoline through the secondary nozzle. Zenith shows its conventional design for different motor types.

Sunderman has a new carbureter, the Mouse Trap, which resembles an oblong box, one-half of which is float chamber and the other half a square cross-section mixing chamber extending from end to end. In this are two nozzles of different heights which are brought into operation by a hinged air valve controlling the air entrance. The lower nozzle begins first.

There are two other unusual carbureter designs. One is the Evans, which has a revolving drum driven from the crankshaft of the engine. This drum is relied upon to break up the fuel rather than relying on a nozzle.

The other unusual type is the Pagel, a syphon type in which there is no float chamber, the gasoline entering a mixing chamber through a single pipe leading direct from the fuel tank on the car. An air nozzle connected with the explosion chambers of the cylinders projects a current of air against the tip of the gasoline pipe, thereby syphoning the gasoline the same as in an atomizer. It is claimed that the air current created by the explosions in the air cylinders is strong enough to syphon gasoline a height of 18 ft.

Among the other carbureters shown are Juhasz, which is an expanding type with three separate nozzles, and having three separate air passages in the throttle, Shakespeare, Webber, Actus, Diamond, F. A. C., etc. In all of these no new principles are employed. They are either metering pin types, or metering pin combined with air valve control designs.

Electric Systems on Sound Basis

In starting and lighting equipment the show contained scarcely a single true novelty. This is striking testimony to the conclusion reached a few months ago, that the electrical equipment had settled down upon a sound manufacturing basis with most of its original faults and failings eliminated. Most impressive also is the decrease in the number of miscellaneous Ford starters. The big firms who entered the field during 1915 seem to have been wonderfully successful, while the lesser lights among the pioneers have dwindled away.

Great interest at the show is to be noticed as centered upon the Stewart air starter for Fords. This has been announced and on the market for several months and consists of a piston working in a circular cylinder, the whole inclosed in a small steel case that bolts to the front end of the frame, a coupling linking the starter shaft with the crankshaft. A tank, kept filled with compressed air automatically, holds enough air for some fifty starts and each start drives the motor through one revolution with such energy that it spins for three or four more. The outfit is inexpensive and easily attached.

Similarly of the electric starters for Fords, the Gray and Davis, the Disco, the North East, the Westinghouse and the Kemco, to mention just a few, are practically the same to-day as they have been for some time past. Some have detail changes tending to increase efficiency, reduce weight or cut manufacturing costs, but to the user they all appeal as simple electrical machines, easily attached and efficient in service.

There are two new models of electric Ford starter, one being the Bosch and the other the Eveready. The former is an elaborate system combining the ignition service and the starting motor is a separate unit acting on the flywheel, a special split gear ring being clamped to the latter. The Eveready is a single unit machine mounting out in front of the radiator and secured to the crankshaft by a flexible coupling. Electrically, it is a simple machine with no controls requiring any attention. The makers claim that the position chosen is the ideal for a Ford starter, as the weight being central the natural three-point balance of a Ford is not interfered with. They even arrange the battery in a thin case that goes against the front seat so that its weight shall be evenly disposed on either side of the car.

For the Eveready starter is claimed the virtue of reducing vibration, it being said that the flywheel effect of the armature spinning on the front end of the crankshaft steadies the running to a noticeable degree.

Absorbers Reflect Spring Progress

Greater confidence on the part of the shock absorber manufacturer in the spring suspension fitted with the cars is manifested this year. The Hartford Suspension Co. has given up its progressive friction type and concentrated on the continuous friction device, as the company has come to realize that the longer springs enable the car to better absorb the minor shocks. The cantilever, with its great flexibility, has been one of the factors in this development. To meet the requirements of the cantilever, there is a new set of brackets for the Sager shock absorber, which have been added to make the absorber suitable for this type.

Horns and Body Design

The development in horns is an instance of where the accessory maker has endeavored to make his product coincide with the tendency to keep the body lines clear. The Long horn, for example, is made in a new model which permits the horn to be mounted under the hood, although still operated by hand. The horn is controlled by a double Bowden wire which operates the ratchet mechanism. Klaxon horns are now made with horizontal instead of vertical drive, allowing the motor to be mounted in the casing behind the diaphragm instead of below it.

More Electric Vulcanizers

The high spot in vulcanizer design is in the use of more electric and fewer steam types. The reason for this is in the quickness with which the electric designs attain their working temperature. Shaler has a new type for garage use and there is a new Premier portable type for the owner. Both of these are characterized by simplicity and by the quickness with which they can be operated.

Single Cylinder Pumps Gain

In power tire pumps there is a marked trend toward the single cylinder design and even in these single cylinder types, the installations are more compact and smaller than ever before. An example of where compactness has been sought and accomplished is shown in the Kellogg single-cylinder job in which the small diameter, long cylinder has been replaced by a larger bored cylinder which is shorter. Rigidity is secured by the use of a double connecting-rod. Another improvement in pump design is suggested in the Stewart type which, in place of plain pistons, has now pistons which are fitted with rings.

Clocks Are Simpler

Clocks are, on the whole, more easily read and less likely to be neglected as far as winding is concerned than ever before. The Hartford company puts out an electric clock which can be run on any voltage from 2 to 110. It is made in both flush and extended models with black on white or white on black faces. Another clock known as the B-4-U is designed to fit in the center of the steering wheel and of course is always accessible.

Refinements in Speedometers

Speedometer designs are more refined in detail and have not had any radical variations during the year. Perhaps the most significant development is the universal employment of a re-set mechanism which can be employed to put the mileage of the trip odometer at any desired point. Stewart-Warner employs a small button on the face of the instrument which, when pressed, turns all the trip disks back to O. The Jones speedometers are now known as the Johns-Manville and have a wheel reset instead of a knob. The Corbin-Brown uses a large knurled wheel and Van Sicklen now has an instrument known as the Spedistimeter which is a combination speedometer and watch.

Dimmers Are Factors

In electric lights and accessories, the use of scientific dimming devices and convenient spot lights are the big points. The Corning and Guide optical methods which keep the light on the road and yet eliminate the glare, are very good examples of what is being done in this respect. The result of tilting the lamp is improved upon without the bad feature of spoiling the appearance of the car. The J. M. frosted globe with slotted front is still used by this concern and in the way of spotlights, it will be noted that these are smaller, more compact and better mounted than ever before and at the same time are selling for less money.

Salon Is an American Show

Fine Examples of Bodywork Illustrate Trend Towards Convertible Type—Cowl Instrument Boards Disappearing

WHILE broadly speaking the automobile salon at the Hotel Astor is a body show, still there are exhibited a number of polished chassis which give an insight into a field of engineering development in which price has not been the dominant factor. The combination of ultra-luxurious bodywork and engineering design unfettered by price consideration makes the Salon exhibit occupy a unique position and furnishes an exhibition which brings out the latest word in refinement of mechanical and coach design.

This year the Astor Salon is not an importers' salon as there are only five foreign chassis on the floor, and these are not of design new to the American public, Peugeot, Rolls-Royce, Lancia and the Delaunay-Belleville.

The American cars on the floor are the Singer, White, Daniels, F. R. P., Simplex-Crane, Brewster-Knight and Owen Magnetic. In addition to these there is another foreign car on the floor, the English Daimler, which exhibits a town body by Henry Labourdette of Paris. The Holbrook company, body maker of New York City, is showing a Cadillac eight chassis fitted with a Berline design, a Packard with a landaulet and a White with a landaulet body. Healy has several bodies on Locomobile chassis and Bender & Robinson are showing two special bodies on Singer chassis. The regular Singer bodies are also manufactured by Bender & Robinson.

Instrument Board Eliminated

Some of the trends in body design which will no doubt be followed in a short time by the lower-priced American stock jobs are very interesting. The absence of the instrument board is perhaps the dominant note in body trend, the line of instruments in most instances being taken from the cowlboard and placed in a neat setting at the toeboard. In addition to the clock and speedometer in the driver's compartment, the practice is growing to place another clock and speedometer in the second cowl in the tonneau, thus allowing the owner an opportunity to know the rate of the car and time of the day as well as the driver.

Convertible Bodies Are Factors

The tendency toward making the body an all-season proposition is very marked at the Salon. Some of the bodies can be transformed from a limousine into a landaulet and then into a touring car. The Healy company is showing one body on a Locomobile which is a good example of the work. It is what is known as a touring-limousine, but so neatly do the glass sides fold into the body and the pillars which support the limousine roof drop into the lines of the touring car that it is difficult to perceive either in the case of the touring or the limousine arrangement how that body could be transformed from one type to the other.

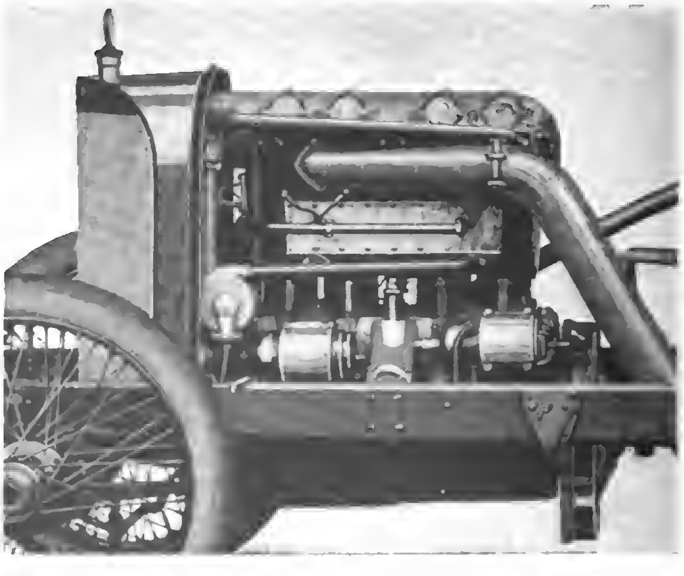
The convertible body and the toeboard instrument set are not universal, however, at the Salon, although they do represent two notable trends. For example, on the Simplex-Crane chassis, the complete cowlboard instrument set is used, and every conceivable type of instrument is arranged across this flat board before the driver. From right to left the outfit includes a voltmeter, clock, air pump, switch block, carbureter adjustment, gasoline gage, oil gage, ammeter, speedometer and odometer. This is the most elaborate cowlboard exhibited, and the line of instruments takes up every available portion of the space which is available across the entire front of the car.

Transmission Brakes Shown

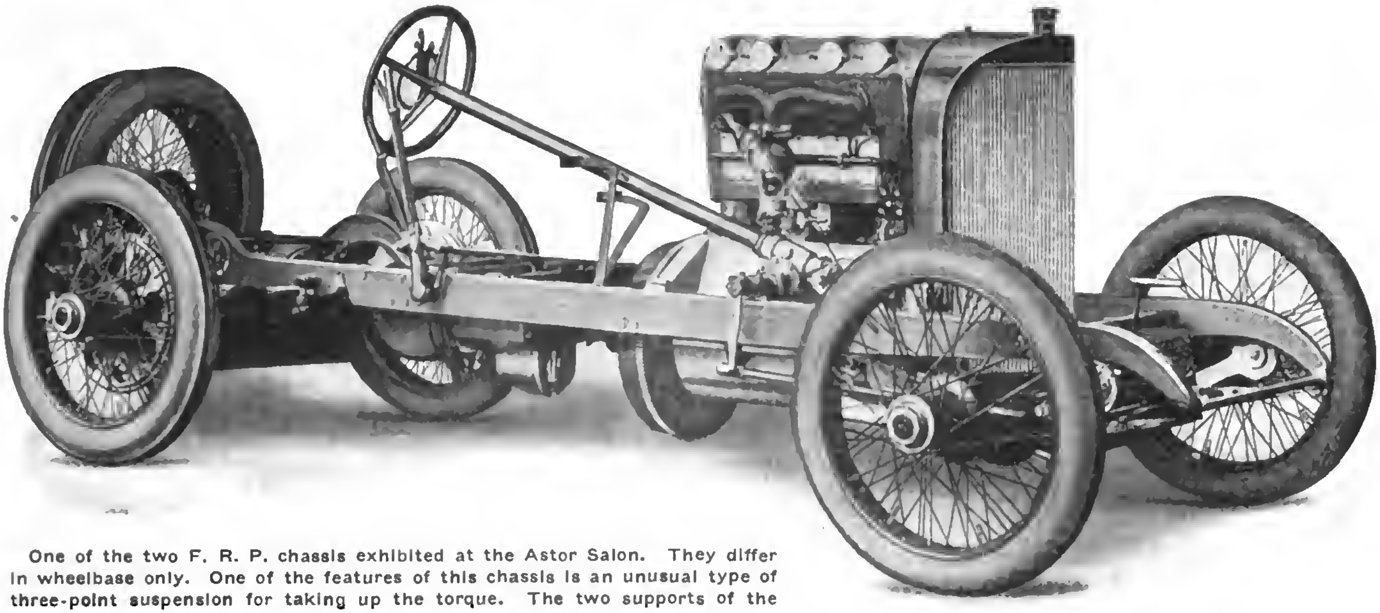
Examples of transmission brakes which are very neatly designed may be seen on some of the chassis exhibited at the Astor. Peugeot has a good example of the transmission type of brake mounted on the forward universal. It is deeply ribbed for cooling and is of great area. Taking this area into consideration with the reduction at the rear axle, there is no doubt that a highly powerful braking action is possible with this construction. The transmission brakes are not confined to the foreign cars, a good example of the installation of the transmission brake on an American chassis being on a Simplex-Crane. Another feature about the Simplex-Crane which is interesting is in the subframe motor support. This subframe starts at the forward end of the main frame and runs back parallel to the main frame member, forming really a frame within a frame. The subframe supports the motor and gives a very rigid support all the way back to the gearset and at the same time acts as an efficient transverse stiffening member to the main frame.

The chain drive chassis has not altogether disappeared from American practice. This is evidenced by the fact that the Simplex chain-drive job is shown in stripped chassis form on the floor. The chains, however, are inclosed in metal cases which permits them to be free of the danger of grit and dirt which was always the big objection to chain drive. The casing about the chain also acts as a silencer and as an oil container.

The F. R. P. chassis is exhibited in two forms, one of short and the other of longer wheelbase. The overhead valve action with the overhead camshaft is exposed, showing a cam contour and drive which is suggestive of big gas passages and high speeds. The cam lines are quite square, giving very quick valve opening and the springs for the valves are short but of heavy section for quick closure. Another interesting point on the F. R. P. chassis is the three-point suspension for the motor. The triangular layout differs from that gen-



Right side of F. R. P. motor, showing overhead valve mechanism



One of the two F. R. P. chassis exhibited at the Astor Salon. They differ in wheelbase only. One of the features of this chassis is an unusual type of three-point suspension for taking up the torque. The two supports of the layout are located just forward of the center of the engine and are in the form of flexible trunnions. The third support is at the rear of the motor

erally found in three-point systems, the two supports being located just forward of the center of the engine and are in the form of flexible trunnions. The third support is at the right rear of the motor which gives a right angle triangle layout of supporting members, with two points on the right side of the frame and one point on the left. The object of this is to absorb the immense torque of the motor which is designed for power and speed without risking the stresses which would fall upon the crankcase member and tend to throw the main bearing out of line.

Subframes Are Strong

It seems to be a distinguishing feature of the cars at the Salon that the subframe structure is extraordinarily sturdy. This is in direct opposition to the tendency to be noted at the Palace show where frame sub-structures and cross-members are if anything, lighter and more flexible than ever before. An example of heavy subframe work is given in the Peugeot stripped chassis. This is one of the 40-hp. jobs and is characterized by this heavy transverse structure which carries the gearbox and also no doubt acts as a torque-absorbing member for the stresses created by the transmission brake. The Singer chassis, which is of American design throughout, provides an interesting study in frame substructure. The F. R. P. is also an example of this and so is the Brewster-Knight. In the latter the subframe bracing is very stiff, the connections being made by heavy gusset plates to the main frame.

A Fine Cabriolet

It is in body work that the Salon has its greatest distinctiveness. A cabriolet designed by J. F. DeCausse of the Healy company is a good example of convertible work. When in the cabriolet position, the body exhibits a town car design which is the last word in luxury. The upholstery is in gray cord and the body itself is gray. In two minutes this body can be transformed into an open roadster, the pillars which support the forward end of the cabriolet top fold downward into the body, the entire top slides backward and folds into such a form that it can be incased in an envelope and the glass sides by the turn of a small crank handle slide into the sides of the body, leaving nothing but a sociable type roadster which is an exact counterpart of designs of the non-convertible type intended only for roadster use. This combination gives an all-year car which is luxurious both in its roadster and in its cabriolet form.

Another Healy body is in the form of a five-passenger sporting model. The interesting point of this is that although the front seats are not divided there is no door to the rear compartment. Accessibility for the passengers is accomplished by having a forward seat which by means of a slight push ahead instantly opens a passage from the forward compartment to the rear seats. The absence of doors in the rear gives the body great strength and lightness, the lines of the roadster and the capacity in spite of this is equal to the average touring car.

Ingenious methods for concealing the extra seats in the seven-passenger touring design are shown in the Singer bodies. These slide into the front of the compartment folding into the back of the front seats and being covered by a shutter. Folding arrangements for seats and body parts are carried out with a neatness which hardly permits of detection of the folding parts. In all of the work at the Salon, the Bender & Robinson special roadster with folding rear deck is a good example of the thoroughness in this work. When the rear compartment is folded open an upholstered seat with upholstered arm rests is provided and when closed the flat deck of the roadster conforms exactly with the ordinary lines of a two-passenger car.

Sedan Bodies Are Popular

Sedan bodies with V-shaped front, the apex being at the front end of the inclosed body, seem to be quite popular. One of these is shown on the Singer chassis, another on the White and also on the Cadillac. These give an added length to the body and add to the appearance of lowness. They are difficult, however, to maintain raintight in front and careful provision has to be made on the windshield for shedding the rain and not allowing it to work through crevices.

Victoria tops also seem to be popular on some of the touring designs. The White company is showing a victoria top on an olive-green touring car which makes a very handsome body. The Lancia victoria top on a top with no running-board gives a combination which shows the ultimate in high-class design.

Sloping windshields are not in as much evidence as they are at the Palace. The Daniels eight has a roadster in which the windshield is raked backward slightly. On the touring car, however, the straight windshield is adhered to. The Daniels landaulet is a regular stock design and is a good example of conservative design in this work. The Daniels eight is not exhibited at Grand Central Palace. It is fitted with a V-type powerplant which is made in either 3-in. bore or 3¼-in. bore with 5-in. stroke. The wheelbase is 127 in. and the tire size 34 by 4½.

The History of the American Automobile Industry—11

The Advent of Onesiphore Pecqueur, Whose Steam Automobile, Patented in 1828, Embodies Practically All Essential Features of Modern Practice Except the Motor

By David Beecroft

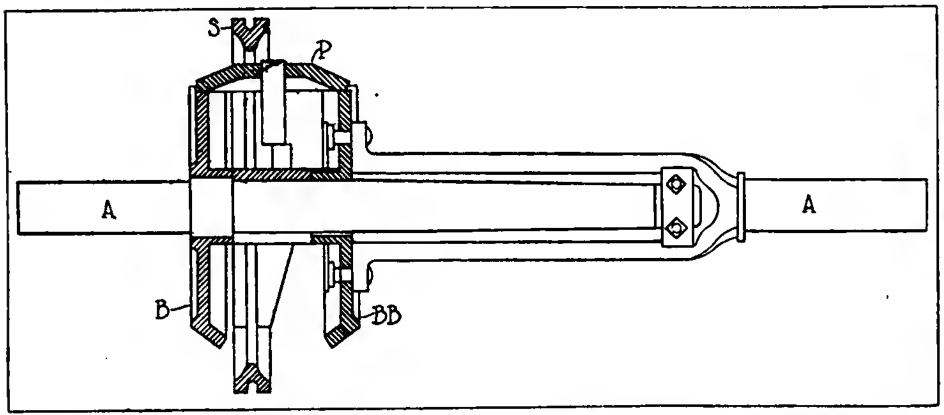
IN the early development of steam no inventor was further ahead of his times than Onesiphore Pecqueur, a very celebrated Frenchman, who in 1828 patented a steam vehicle which embodied practically all the essential features of the modern automobile with the exception of the motor. To Pecqueur should be ascribed the title of Father of the modern automobile. His patent drawings of April 25, 1828, show that he employed the accepted type of automobile steering gear as we have it to-day, Fig. 1, although each front wheel is carried in a bicycle type fork by itself and a front axle connecting the two wheels is not used. Fig. 2 shows how he combined the two front wheels by using steering arms and the cross tie rod employing also a rack-and-pinion type of steering gear.

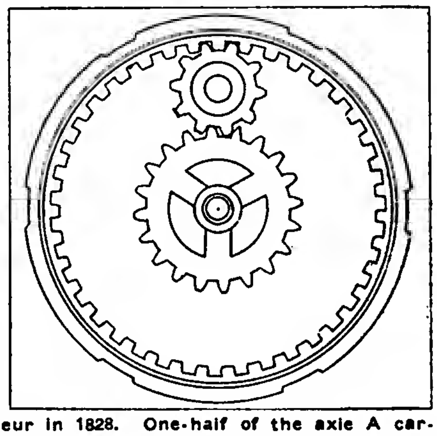
First to Use Differential

Pecqueur, in addition to being the first to patent the present-day steering gear, was also the first to use a differential or balance gear in the rear axle. Fig. 3 is a plan view of the complete Pecqueur steam vehicle and shows the differential mounted in the axle proper, and Fig. 4, a section of this axle, gives further details. Fig. 5 shows the complete details of the first modern type of differential ever employed in the automobile.

But Pecqueur went further and used a planetary gearset giving two forward speeds, the reverse not being necessary because of using a steam engine which could be reversed. Not requiring a reverse or friction clutch, his patents show a jaw or positive clutch which he used in connection with his speed-change planetary gearset.

His patent drawings show very plainly a rear axle in two parts, one forming a sort of sleeve over the other, and each carrying a bevel gear with a spider carrying a bevel pinion and a sprocket for a chain, practically identical with the Duryea, Knox and other constructions in common use at the end of the nineteenth century. He employed the fixed front axle with steering knuckles and short spindles now universally used, a device which was patented by Rudolph Ackerman, an Englishman, in 1818, for use on horse vehicles. His engine was a type of rotary and evidently not a very practical affair, which probably accounts for nothing more being heard of his device. One of the advantages of the Ackerman steering as exploited in those early days was "lessened danger of upsetting." It was argued that a continuous axle and king bolt gave but one point of support for the front end of the vehicle, whereas the Ackerman device constantly maintained a support at each front corner. This argument would be more valuable if uneven roads did not demand a considerable flexibility of structure, which must be supplied by springs, three-point support or in some equivalent manner.





Left—Fig. 5.—Complete section of rear axle with bevel differential invented by Pecqueur in 1828. One-half of the axle A carries the bevel gear B; and on the other half of the axle is carried the other bevel gear BB. One of the pinions P is shown, as is the sprocket S for single chain drive. Instead of dividing the two halves of the axle as we do to-day, Pecqueur made one half in the form of a sleeve or tube within which he carried the inner end of the other half

Right—Fig. 6.—Type of two-speed planetary gearset employed by Pecqueur on his steam vehicle of 1828. To change the speed of the engine with relation to the rear wheel the driver pushed a small handle which regulated the planetary gearset, which operates in the conventional planetary gear manner as in use at present

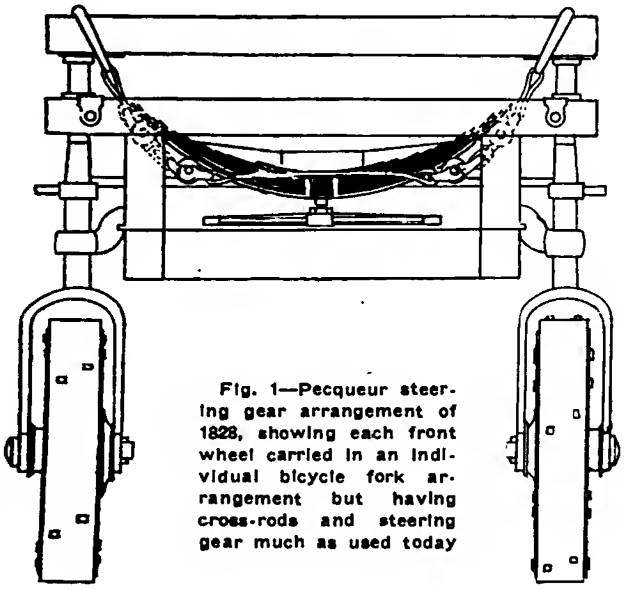


Fig. 1—Pecqueur steering gear arrangement of 1828, showing each front wheel carried in an individual bicycle fork arrangement but having cross-rods and steering gear much as used today

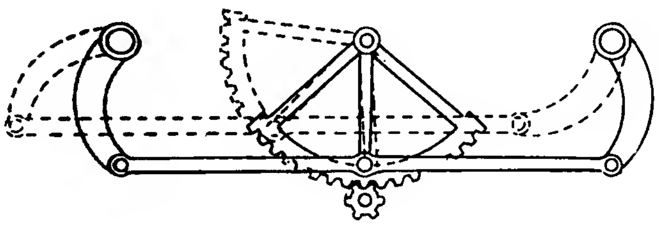

Fig. 2—Diagram of rack-and-pinion type of steering gear used on Pecqueur steam cars in 1828, showing the use of steering arms and cross-tie rod, the same as employed in steering at the present time

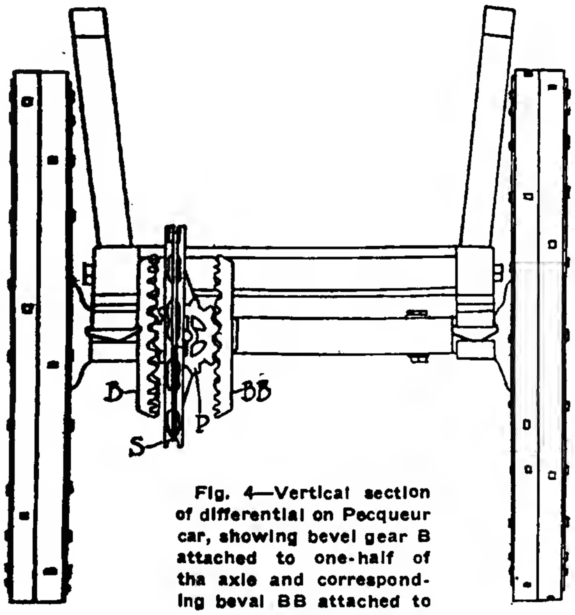

Fig. 4—Vertical section of differential on Pecqueur car, showing bevel gear B attached to one-half of the axle and corresponding bevel BB attached to the other half. Between them is mounted one of the balance pinions P and outside is the sprocket S for chain drive

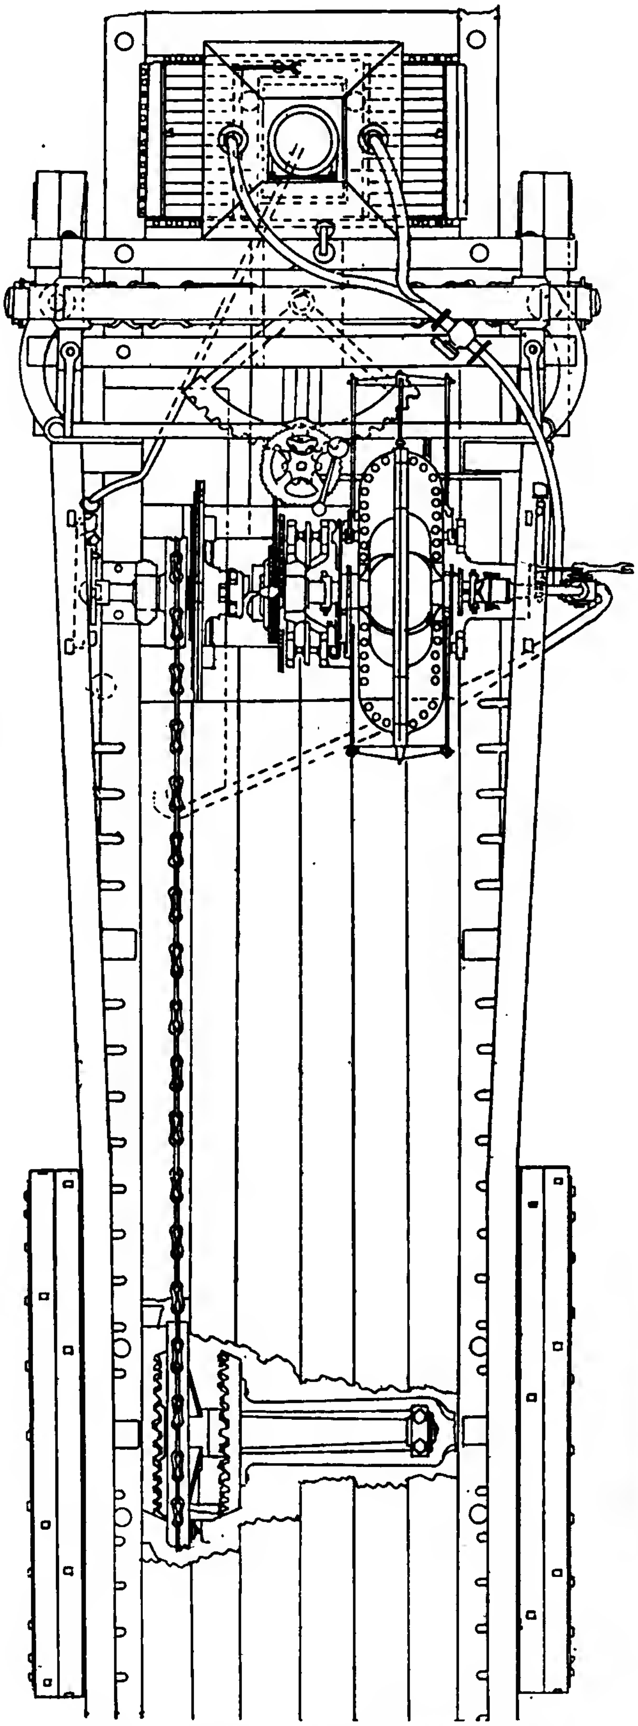

Fig. 3—Plan view of Pecqueur steam car, 1828, which merits being known as the father of the modern automobile in that it employed for the first time the modern steering gear, a two-speed planetary gearset, and a divided rear axle carrying a modern type of differential

The Rostrum

Chipped Gears Cause Differential Knock

EDITOR THE AUTOMOBILE:—I noticed a knock in the differential of my car which is a 1911 model Oakland 33 and after washing out the housing noticed a piece of steel lodged between the teeth of the large bevel gear. Last week a similar piece produced a knock. On observing the large bevel gears through the pipe-plug hole, I cannot detect the wear, but am unable to examine the small pinion without disassembling the housing. End play in the axle is not over 1/32 in. as tested by jacking up the wheels. Heretofore I lubricated the differential with steam cylinder oil, 600 W. and am now using light motor oil. The car runs all right and I would like to know whether I should continue using it or have the differential housing disassembled?

Dubuque, Iowa. W. E. C.

—The differential housing should be disassembled immediately for the purpose of determining what is giving way in the gears.

From the explanation you give it would seem that the gears had become chipped which will result very often from careless handling of the car, that is, by dropping in the clutch when the motor is speeded or by applying the brakes heavily. It can also be produced by mental fatigue due to long service.

Wiring Diagrams for Installing Ammeters

Editor THE AUTOMOBILE:—Will you please publish a wiring diagram for installing ammeters on models B-55 and C-55 Buick cars so as to show the discharge when the starter and lights are in use? Also, the rate of charge from the generator to the battery?

Barre, Vt. H. & M.

—The wiring diagrams for installing ammeters are furnished herewith, the diagram for Buick model B-55 being shown in Fig. 2 and for C-55 in Fig. 1. The rate of charge from the generator to the battery will depend entirely on the speed at which the car is operated, but it should not exceed 18 amp.

Second Speed Gear Slips Engagement

Editor THE AUTOMOBILE:—What would be the cause of the second speed gear slipping out when pulling up a hill. It is a Lozier type 82. I have deepened the notch in the shifter rod and also tightened the plunger spring, but without success.

Montreal, Que. W. O. G.

—It is probable that the second speed plunger has become worn and needs replacing and it may also be that the spring has become weakened and needs to be replaced with a new extra heavy spring.

Installing Ammeter on Hudson 6-40

Editor THE AUTOMOBILE:—Please publish directions for installing an ammeter on a 1914 Hudson model 6-40. What size wire should be used?

Lancaster, N. H. H. M. M.

—There are two terminals on the side of the generator, one immediately above the other. From the upper side of these two terminals a wire leads to the ignition and lighting switch and from the lower one a heavy cable leads to the storage battery. Immediately beneath the terminals is a brass strip forming an electrical connection between the two. All current going into the storage battery and all current coming out of it, with the exception, of course, of the cranking current, passes through this brass strip.

To connect an ammeter in the circuit, therefore, this brass strip may be removed or simply severed, using a hack-saw blade for the purpose, and the ammeter is then hooked up with the positive side connected to the upper terminal and the negative side connected to the lower terminal. No. 10 wire should be used.

Carbureter and Line Need Cleaning

Editor THE AUTOMOBILE:—I have a six-cylinder Albatross motor radial type with Remy magneto and Schebler Model D carbureter. When I prime the motor it gives about six revolutions and then stalls. The carbureter is new and the spark seems to be all right as it runs when I prime it.

Kindly advise me what your opinion is. Before starting I open the needle valve about two turns and open throttle about half.

Cleveland, Ohio. L. M.

—Evidently there is a stoppage somewhere, either in the tank or in the line between the tank and the carbureter or in the carbureter itself.

If the carbureter is taken off and thoroughly cleaned out and the tank and line are cleaned out, you should have no further trouble, as there is unquestionably dirt or foreign substance somewhere between the gasoline tank and the carbureter or in the carbureter in the nozzle, preventing same feeding properly.

Wants 1911 Regal Instruction Book

Editor THE AUTOMOBILE:—I would like to inquire through the columns of the Rostrum whether any of your readers has a copy of the instruction book issued by the Regal Motor Car Co., for its 1911 torpedo roadster, for which he has no further use?

I endeavored to obtain this book from the Regal Motor Car Co., but was informed that it was out of print and that they did not intend to reproduce the same. I would be glad to pay any reasonable price for the book.

New York City. P. F. S.

Steam Turbines Impractical for Cars

Editor THE AUTOMOBILE:—In THE AUTOMOBILE for Dec. 9, S. T. asks the question, "Could a steam turbine be used in the Stanley steam car to furnish the motive power? If not, why?"; and you reply, "No, because it has not so far been possible to make a steam turbine in small sizes." I beg to differ with you on this point.

To my certain knowledge steam turbines are made in very small sizes by several manufacturers and are used for a variety of light power work such as driving exhaust fans, blowers, cream separators, etc. The reason that a turbine is not a practical drive for the Stanley or any other steam-

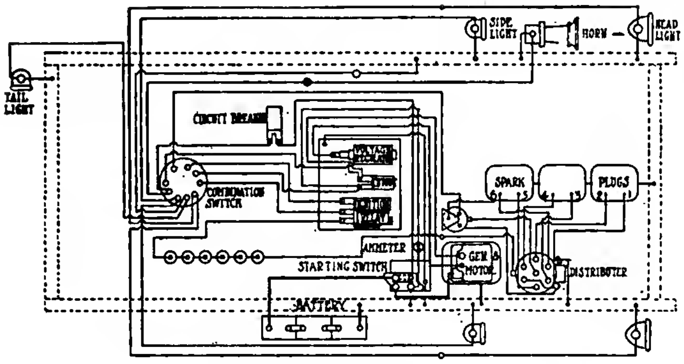

Fig. 1—Wiring an ammeter on a Buick C-55

propelled vehicle is because it has the inherent defect of possessing almost no starting torque. Steamships would be unable to use turbines but for the fact that there exists a large amount of slippage between the propeller blades and the water when starting slowly, and consequently very little load comes on the turbine till a high enough speed is attained to create sufficient friction against the propeller thrust to move the boat through the water. By this time the turbine has acquired momentum and is enabled to continue merrily on its way.

Newark, Del. R. R. W.

Must Keep Battery on Line

Editor THE AUTOMOBILE:—Will you please advise us what effect it has on a Delco generator to run a car with the storage battery removed, providing the wires are taped so that they are unable to ground?

Oneida, N. Y. O. M. C. Co.

—On none of the apparatus produced to date should a car be driven with the storage battery off the line. With the battery off the line the voltage of the generator rises to a very high limit so that it will burn out the headlights and also have an injurious effect on the ignition.

Replies to Hartford's Gnome Criticism

Editor THE AUTOMOBILE:—I noticed in THE AUTOMOBILE for Nov. 11 a criticism of an article on the Gnome rotary cylinder aeroplane engine. In this article Mr. Hartford says that the engine in question is also a reciprocating motor in that the pistons reciprocate in the cylinders. So far he is right, but he has failed to analyze further. The relative movement of the pistons and the cylinders is one of reciprocation, but the actual movement is rotary around a given center.

The cylinders revolve uniformly around the center of the crankshaft. The pistons revolve around the center of the crankpin. Owing to the design of the connecting-rods in the Gnome motor, the pistons do not revolve with a uniform speed exactly, but this difficulty has been overcome.

Mr. Hartford has fallen into the error of not appreciating the difference between relative and actual motion.

One pound of weight at 1 ft. from the center revolving at 1100 r.p.m., produces a centrifugal pressure of 412.6 lb.

San Francisco, Cal. A. F. B.

Information on Fuel Feed Systems

Editor THE AUTOMOBILE:—Will you kindly inform me of the relative merits of the several types of gasoline feed? So far as I know there are three types: gravity, vacuum and force feed, by air pressure. Of whom may I obtain literature on vacuum feed? I have air pressure feed and am always uneasy about leaks developing. Can one feel more secure with other types, or is he warranted in feeling greater security?

Norfolk, Va. M. E. R.

—Gravity feed, though usually efficient in level districts, sometimes fails to give best results when ascending steep grades. Even if entirely efficient, gravity feed requires location of the main gasoline tank either in the cowl or under the front seat, locations both dangerous and inconvenient.

Pressure feed requires an elaborate system of tubing and pressure pump, and needs constant attention on the part of the driver. Leaks are frequent. Its construction permits carrying the gasoline tank in the rear where it belongs, while at the same time forces the gasoline to the carbureter faster than needed, resulting in waste because of unconsumed gas.

Vacuum feed permits carrying the main gasoline tank in the right place, that is, in the rear, and carries gasoline unfailingly to the carbureter, without attention. A saving of gasoline consumption of from 10 to 12 per cent is shown over pressure feed, although no saving in fuel consumption is shown over gravity feed.

Proper Firing Time on 1911 Elmore

Editor THE AUTOMOBILE:—I have a 1911 Elmore 30 touring car on which I broke the timer arm. I would greatly appreciate it if you could send me instructions to time the ignition on this particular motor. It is equipped with an Atwater Kent system. The main trouble which I have had is to find the position of the distributer and piston at the proper firing time.

Cortland, N. Y. R. E. A.

—The spark in No. 1 cylinder should occur when the piston is between compression and power strokes.

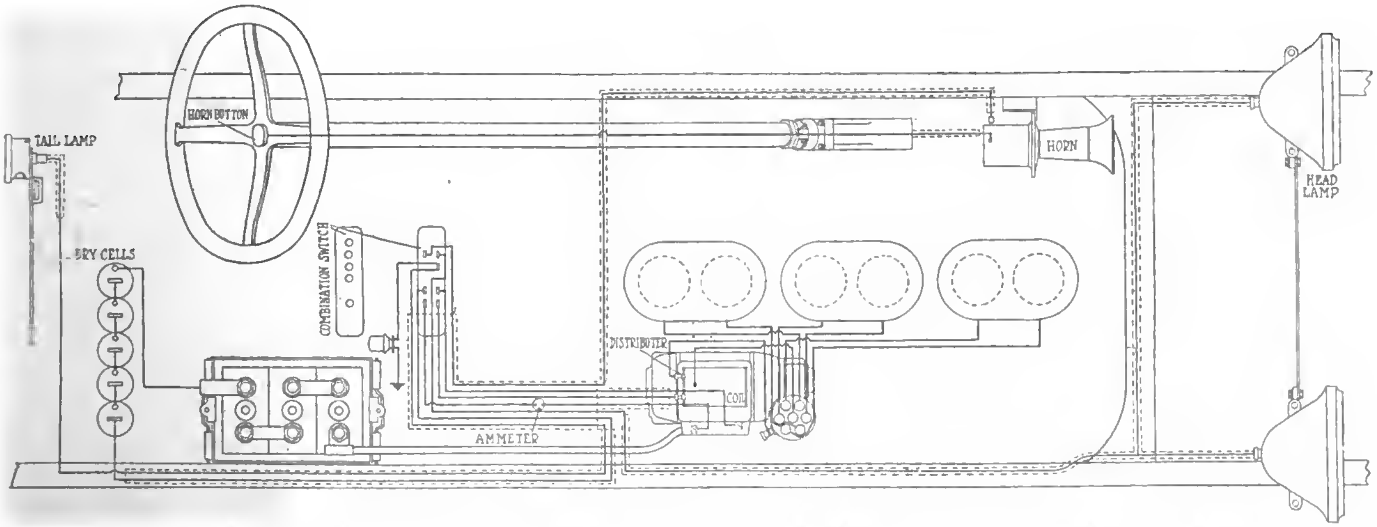

Fig. 2—Wiring diagram for installing ammeter on model B-55 Buick. Insert ammeter in No. 10 red wire between generator and switch

Bakelite—A Synthetic Resin

Formed by a Chemical Reaction Between Carbolic Acid and Formaldehyde—Used as an Insulator for Electric Starting, Lighting and Ignition Systems

ONE of the most noteworthy chemical achievements of recent years has been the work of the well-known chemist, Dr. L. H. Baekeland, in the line of phenolic condensation products which has resulted in giving to the world an entirely new and useful synthetic product, now familiarly known as Bakelite—or sometimes described by its more formidable chemical name of oxy-benzyl-methylen-glycol-anhydrite.

A Commercial Success

To the lay mind it is somewhat puzzling that two strong-smelling liquid substances—carbolic acid and formaldehyde—can be made to unite chemically with each other so as to produce a solid, transparent, amber-like substance, absolutely without taste or odor, and possessing entirely new chemical and physical characteristics. Yet this is exactly what is accomplished in the manufacture of Bakelite. In chemical products of this kind there is usually a wide gap between the laboratory stage and the final commercialization of same—but in the case of Bakelite it is an interesting fact that its commercial introduction met with almost instantaneous success, and the material is now being successfully used in a wide range of varying applications.

Bakelite in its pure form is a transparent, amber-like substance of marked chemical inertness. Physically, it is heat-resisting, mechanically strong, a high dielectric, impervious to most acids, steam and oils, and cannot be dissolved by any known solvents. In this form it is used for pipe stems, parasol handles, fountain pens, jewelry and similar applications.

A Good Insulator

For electrical insulation the pure Bakelite gum or resin is incorporated with various filling ingredients which give it strength, toughness, and other desirable qualities. Its largest, and perhaps most interesting application, is in the line of electrical insulation, where it seems indeed to have filled the proverbial long felt want and is now employed with notable successes in the electrical industry. It seems to have been particularly successful as applied to automobile ignition work. Bakelite does not burn or soften with heat like hard rubber or the shellac compositions; neither does it deteriorate with age or suffer injury from oils or moisture, which makes it peculiarly suitable for distributer blocks and other parts of electric starting, lighting and ignition systems. A large proportion of the leading lighting and ignition systems now use Bakelite insulation because ignition engineers must provide a dependable system, and dependability is largely a matter of high-grade insulation which is proof against heat and moisture.

Aside from strictly electrical applications, Bakelite is being successfully used on automobiles for many purely mechanical applications, such as radiator and gasoline tank caps, steering wheels, door strips, etc. And perhaps in no other use has it justified itself more fully than in the molding of delicate instrument covers, where extreme accuracy of dimensions, fine finish, permanency of color and chemical stability are of primary importance.

The Bakelite molding process is simple and very interesting. Steam-heated hydraulic presses are usually used for this purpose, the molding temperature being approximately 350 deg. Fahr. (120 lb. steam) and the hydraulic pressure from 1500 to 2000 lb. per square inch of mold surface. Hardened steel dies are necessary to insure the best results. The molding material is pre-

(*Continued on page* 50)

Good examples of Bakelite used as insulation and for other useful purposes in automobile design

New York's Sixteenth Show

THE sixteenth annual New York automobile show is unique in that it can be called the freakless show, a show without a single novelty-row candidate in the sense we have annually studied such during the past sixteen years. Every car in the show is a full-grown vehicle, a thought-out machine and not a sensation creator. In the accessory division the same freakless program prevails, in fact, freakiness is not present; it is not a symptom much less a factor in the atmosphere. For the time at least the creator of some pet hobby that an inventor has ridden to death, is not in manufacturing favor. To-day you walk through the four floors of the show, look over the 326 chassis and cars and glance at the hundreds of accessory exhibits and the dominating influence is one of feasibility, of practicability, of accomplishment.

For a new industry to discard entirely its sensationalism in less than a score of years, in approximately one-half a generation, is an accomplishment that few industries can boast of. It is but a score of years since America witnessed the practical birth of the automobile in the Times-Herald-Chicago race, and yet in that brief span much of the story of evolution has been written.

The present show demonstrates the impossibility of any one feature of construction stampeding the industry. The days of stampedes may return but the industry has emerged from a strenuous two-year test with eights and twelves, as the major stimulants to stampeding, and yet the spirit of developing along varied lines is stronger than it was a year ago. The makers are more busy in improving the general chassis and body rather than warring with one another for supremacy in some particular designs. The story of the industry's growth is a very general one, embracing all branches of the automobile. This healthy condition is certain to make the automobile a better balanced machine and at the same time serving as an adequate antitoxin to stampedes, which have been characteristic of many makers for many years.

Dimmer Regulation

OFFICIAL automobiledom has taken its first definite step in suggesting adequate ordinances to regulate the glaring headlight that is menacing our highways. By its recommendation of what a good light is, the Standards Committee of the Society of Automobile Engineers has set up an anti-dazzle bogey, which has been demonstrated as safe, conservative and yet adequate for the average automobilist. The recommendation is particularly opportune, coming as it does before the legislatures begin their country-wide annual campaign of anti-motor legislation. The recommendation is a sane suggestion for all legislators and one that no manufacturer or sane automobilist could reasonably object to.

By requiring adequate illumination to distinguish objects on the road at a distance of 150 ft., to distinguish objects on either side of the roadway at a point 10 ft. in advance of the car, and by requiring that the beams of light shall not be over 42 in. from the ground at a point 75 ft. or more in advance of the vehicle, the committee has practically covered the essentials of anti-glare legislation. Their recommendation is particularly commendable in that it makes no endeavor to suggest means of correcting existing glare devices, but rather leaves that to the versatile and inventive genius of the industry. There is not a single recommendation as to how the problem might be solved; only a sane recommendation as to the safety requirements that are necessary in connection with night driving. The recommendations have not been based on mere guesswork but are practically in accord with the findings of various investigating committees that have been analyzing headlight glare conditions in various cities during the past year. The general meeting of the society, held the day following that of the standards committee saw fit to modify this resolution, leaving only that part relating to restriction of light below 42 in., at 75 ft., and beyond and eliminating the parts defining adequate driving light. It seems a pity that the finding of the committee was not backed up by the general meeting; a pity that the membership as a whole has shown itself less courageous than the standards committee. Still the fact that the standards committee approved the resolution is of immense importance, for it means the whole society may approve something equally good before long.

Kelly-Springfield Raises Tire Prices

Increases Range from 7½ to 26%—More Cos. to Raise Lists

NEW YORK CITY, Jan. 4—The looked-for increase in the price of pneumatic tires which was expected to be announced by nearly all of the tire manufacturers Jan. 1 has been announced by only one concern, Kelly-Springfield, whose new prices represent an increase ranging from 7½ per cent on the smaller sizes such as 30 by 3 to approximately 26 per cent on such sizes as 37 by 5. Although none of the other companies has given any intimation of a rise, it is generally rumored in tire circles that one will come Jan. 8.

The present rise is due entirely to increase in the price of rubber, which has risen from 57 cents a pound in September and October to $1.05 yesterday. The rise in price, which has been going on steadily since Nov. 1, started with the reported closing of the Suez Canal, and although this great waterway through which comes all of the crude from the Federated Malay States and Ceylon has not been closed, the rubber price nevertheless has continued to rise. To date only one boat carrying rubber from the East has been torpedoed, this being the Langeon Hall with 500 tons of crude, which was torpedoed early in December. This loss is not sufficient to create any increase in price. At present 60 per cent of the crude used in America comes from the East, and while there has been no shortage of supply, the increase is largely due to the increased demand for rubber. This is due to the greatly increased number of cars in use, and is also due to the large increase in exports,. particularly solid tires, to certain of the belligerents.

Some of the Kelly-Springfield prices, new and old lists, follow:

Size	New	Old
30 x 3	$16.35	$15.20
34 x 4	32.95	27.45
34 x 4½	40.55	33.80
36 x 4	35.00	29.15
36 x 4½	42.95	35.80

N. A. C. C. Banquet Breaks Record

NEW YORK CITY, Jan. 5—The annual banquet of the National Automobile Chamber of Commerce, Inc., held last night at the Waldorf was one of the largest gatherings of automobile manufacturers in the history of the chamber, and perhaps the largest social event of show week. Three hundred men attended, the number representing the majority of the industry. In the absence of Charles Clifton, president of the chamber, due to illness, Wilfred C. Leland, Cadillac, presided. Senator Gore of Oklahoma was the only speaker and discussed preparedness from its many angles.

An entertaining novelty of the dinner was the menu which took the form of a stock certificate for 1000 shares of stock in the Blue Sky Motor Car Co., incorporated under the State of Collapse. Another novelty was the decorating of five automobile manufacturers for conspicuous accomplishments, the decorations taking the form of huge burlesque medals hung by red ribbons around the necks of the recipients. Those so decorated included John N. Willys, designated as the prince of production; Harry W. Ford, Saxon, for his financing; George Kissel as the knight of the all-winter body; and John F. and Horace E. Dodge for what they have done, their medal being split in two, each receiving a half.

Franklin Declares 100 Per Cent Stock Dividend on Common

SYRACUSE, N. Y., Jan. 5—The H. H. Franklin Mfg. Co., this city, has declared a 100 per cent stock dividend on its $900,000 outstanding common stock, payable Dec. 31. Cash dividends for the last half of the year total 38 per cent, one of 10 per cent having been declared for Dec. 31. The common stock was increased to $2,000,000. There is $600,000 preferred in the treasury.

The production for 1916 will be 3800 cars. The company at the first of the new year is two months ahead in orders for cars for delivery to the dealers.

White Motor Co. Elects Directors

CLEVELAND, OHIO, Jan. 4—At a meeting of the White Motor Co. held in this city to-day, the following were elected directors of the company: Warren Bicknell, E. W. Moore, Otto Miller and J. R. Nutt of Cleveland; J. H. Harding, of C. D. Barney & Co., Theodore Roosevelt, Jr., of Montgomery, Clothier & Tyler, E. R. Tinker, vice-president of the Chase National Bank of New York, and A. M. Hall, vice-president of the Liberty National Bank, all of New York.

Windsor T. White will shortly be added to the board and made president of the company. Other members to be included are: Walter C. White and M. B. Johnson of Cleveland.

Keim N. Y. Locomobile Manager

NEW YORK CITY, Dec. 31—Seymour de Benneville Keim has been appointed manager of the New York branch of the Locomobile Co. of America to succeed J. F. Plummer who resigned as manager of the New York branch a few weeks ago to pursue other business interests. Mr. Keim for several years has been manager of the Philadelphia branch, where he will be succeeded by Arthur Prince Hawes, at present manager of the Boston branch of the Locomobile company.

$3,000,000 Packard Preferred

New Issue of 7% Cumulative Stock Offered at 104 and Accrued Dividend

NEW YORK CITY, Jan. 3—The Packard Motor Car Co., Detroit, Mich., has sold $3,000,000 of 7 per cent cumulative preferred stock to William A. Read & Co., this city, and the latter concern is offering it to the public at 104 and accrued dividend. This stock is callable at any time on ninety days' notice at 110 and accrued dividend per share, and is subject to redemption at par on Aug. 30, 1939.

The cash received by the Packard company from the sale of this new stock will place the company in a position which will enable it to redeem all its outstanding debenture notes, which fall due next December.

The statement of the Packard company for its fiscal year ending Aug. 31, 1915, and published in THE AUTOMOBILE for Oct. 28, showed that the net current assets of the concern were approximately $10,000,000, and that the total tangible assets after very liberal deduction for depreciation were approximately $21,000,000. In the last fiscal year the company's net income available for preferred stock dividends, after depreciation reserves of more than $1,300,000, was $2,265,926. In the past five years investment in the property of surplus profits and reserves exceeded $13,000,000.

Packard 10 Per Cent Stock and 1¾ Per Cent Cash Dividend

DETROIT, MICH., Dec. 31—As a fitting climax to the ending of its busiest year, the Packard Motor Car Co. to-day announced that common stockholders will receive a 10 per cent stock dividend in addition to a cash dividend of 1¾ per cent. Payment will be made Feb. 1 to holders on record Jan. 15.

This is the first time a cash dividend is declared on the common stock. A 40 per cent stock dividend was declared Oct. 16, 1913.

Including the stock to be distributed Feb. 1, the total outstanding common stock will be approximately $7,771,830 out of the total of $8,000,000 authorized issue.

Reliance Engineering Capital, $1,720,000

LANSING, MICH., Jan. 3—The Reliance Engineering Co. has increased its capital stock from $1,250,000 to $1,720,000. This company recently took over the Saeger Engine Works, the Michigan Crank Shaft Co., and the Emergency Forge Co.

Chevrolet-G. M. C. Deal Strikes Snag

Eight of G. M. C. Directors Opposed to Merger Plan—Voting Trust Proposed

NEW YORK CITY, Jan. 4—A conference of directors of the General Motors Co., held in this city recently developed the fact that a majority of the directors of the company are opposed to the plan for a merger with the Chevrolet Motor Co., advanced by W. C. Durant, who proposed turning a controlling interest in the larger company over to the Chevrolet by means of an exchange of stock. The capital of the latter company, as a result of the plan, was increased from $20,000,000 to $80,000,000.

A letter has been sent to the General Motors stockholders by eight of the fourteen directors of the company stating that they are not a party to any arrangement looking to the vesting of control of the General Motors Co. in any other company, and that they favor the formation of a three-year voting trust beginning November, 1916, at which date the term of the present board of directors expires. These directors ask the stockholders to signify whether they wish to unite in forming such a voting trust, and state that if a sufficient number of the stockholders so desire, action to that end will be taken. The voting trust proposed, which they say is favored by a majority of the board, is to be made up of five members of the present board as trustees, to be selected by the present directors. The statement sent to the stockholders was signed by S. F. Pryor, A. H. Wiggin, Thomas Neal, C. H. Sabin, J. J. Storrow, C. S. Mott, Albert Strauss, and E. W. Clark.

Peerless Stock Syndicate Dissolved

NEW YORK CITY, Jan. 5—The Peerless Truck & Motor Corp. stock syndicate, which expired by limitation Jan. 3, has been dissolved and will not be renewed. This means that there are now no restrictions on the sale of the stock by subscribers.

In a statement sent to shareholders President Frederick Gilbart states that the aggregate sales by the company in the eleven months ended Nov. 30, 1915, were $11,458,513 and that net profits, after deduction of charges for maintenance and depreciation, before deducting interest obligations, cancelled or provided for in the formation of the corporation, were $1,903,058. This is at the rate of $9 a share per year, 18 per cent of par value, on the entire outstanding capital stock of $10,000,000, after providing for interest on the corporation's 6 per cent convertible gold notes now outstanding.

The consolidated balance sheet of the subsidiary companies of the Peerless Truck & Motor Corp., as of Nov. 30, follows:

ASSETS	
Patents, franchises and goodwill.. ($5,000,000 represented by common stock of General Vehicle Co., Inc., as per contra.)	$5,100,000
Land, buildings, plant and equip..	4,816,586
Investments	511,035
Inventories	1,428,265
Accounts and notes receivable....	655,695
Cash in banks and on hand........	2,147,008
Prepaid expenses and insurance..	65,418
Development, engineering ex., etc..	184,636
Total	$14,908,646

LIABILITIES	
Peerless Motor Car Co. 7% cum. pf.	$2,100,700
Peerless Motor Car Co. com. stock.	2,085.500
General Vehicle Co., Inc., 7% cum.pf	1,200,000
General Vehicle Co., Inc., com. st'k. (This amount represents patents, fr'nch's, goodwill as per contra.)	5.000.000
First mtge. serial gold 6% bonds of the Peerless Motor Car Co........	900,000
Less—Since retired or to be retired by the Peerless Motor Car Co...	300,000
Mortgage on real estate in N. Y. C.	300,000
Special deposits	175,490
Accounts payable	734,288
Peerless Truck & Motor Corp. advance	50,000
Sundry creditors, including accrued payroll	114,304
Reserves against inven., doubtful accounts, etc....................	250,360
Surplus capital created by cancellation of notes payable of General Vehicle Co., Inc., as of Oct. 31, '15.	900,000
Surplus	1,398,003
Total	$14.908,646

Standard Steel Car Takes Model Engine—To Double Output

PITTSBURGH, PA., Jan. 3—The Standard Steel Car Co., this city, has taken over the Pittsburgh Model Engine Co., with plants in Pittsburgh and Peru, Ind. The Model Engine Co.'s assets in property, buildings and machinery, when taken over, exceeded $1,000,000.

The production of Standard cars is to be doubled and the manufacture of Pittsburgh Model engines for the trade will be continued.

Six Hupmobile Men Promoted

DETROIT, MICH., Jan. 4—The Hupp Motor Car Corp., this city, has made a number of promotions in the factory organization, effective Jan. 1.

Lee Anderson, formerly sales and advertising manager, becomes commercial manager in charge of sales, service and advertising. J. E. Fields, formerly director of the Hupmobile national coupon service plan and special sales representative, becomes sales manager, with H. E. Westerdale as his assistant.

Frederick Dickinson, formerly assistant advertising manager, becomes advertising manager. R. D. Heartz, formerly assistant to Mr. Fields, becomes sales promotion manager. J. S. Patterson, who has handled the Hupmobile publicity, becomes assistant advertising manager. J. L. Kenyon becomes general service manager in charge of technical service, parts stock and orders and claims.

Calls for Gasoline Price Probe

Congressman Introduces Resolution Demanding Punishment of Price Boosters

WASHINGTON, D. C., Jan. 4—That the rapid increase in gasoline is almost certain to bring about a Federal inquiry was indicated to-day when the attention of Congress was directed to it. Congressman Steenerson of Minnesota, introducing a resolution calling upon the Department of Justice to advise whether it has begun prosecutions against those responsible for the increased prices. Price of gasoline in Washington was to-day advanced 1 cent a gallon from 20½ to 21½ cents.

The preamble of the Steenerson resolution asserts that the present price of gasoline is "unreasonable and extortionate" and that it is sufficiently high to injure the industries of the United States.

The resolution directs the Attorney-General to advise what steps he is taking in connection with reports that dealers in the commodity are violating the Sherman anti-trust law. If the department has not begun prosecution, the resolution provides, the Attorney-General shall explain why such prosecutions have not been started and if they are contemplated. The Steenerson resolution was referred to the judiciary committee.

"We will answer the resolution when it comes to us," said Assistant Attorney-General Todd this afternoon when advised of Congressman Steenerson's action in the House.

Monihan Forms New Company

NEW YORK CITY, Jan. 5—John G. Monihan, has resigned from active participation in the affairs of the Mutual Motors Co., of Jackson, Mich., and has formed a company of his own, known as the Co-operative Exhibitors of Motor Cars, with headquarters in Detroit, and offices in Cleveland and Buffalo. Mr. Monihan states that the purpose of his new concern is to distribute automobiles, but does not as yet announce the name of the car he is to handle, although it is understood that this will be an entirely new make.

Mr. Monihan retains his position as a stockholder of the Mutual company and as a member of the board of directors.

Snell Interstate Production Manager

MUNCIE, IND., Jan. 4—F. E. Snell, who was connected for many years with the Service Motor Truck Co., Wabash, Ind., and the Garford Motor Truck Co., has taken over the duties of production manager of the Inter-State Motor Co.

Gasoline Higher Despite Increase in Crude Output—Retardation Charged

Dept. of Justice and Federal Trade Commission Both Prepare to Investigate Reasons Given for Increasing Price of Fuel—220,000,000 Bbl. of Crude Held in Reserve

WASHINGTON, D. C., Jan. 1—With both the Department of Justice and the Federal Trade Commission preparing to investigate gasoline prices and with the probability that Congress will also take a hand in the matter, the subject is sure to receive a lot of attention during the next few weeks. Official government figures just made public disclosed that in the face of rising prices of gasoline, production of crude petroleum during the last year was greater than in 1914, although production was "purposely retarded as far as practicable," that reserve stocks of crude petroleum now being held in the country are the largest ever recorded, and that exports of gasoline, to which the rise in prices frequently has been attributed, were in the last ten months of 1915 less than the exports during the corresponding period of the two years previous.

A statement issued by the Geological Survey estimated the 1915 production of market petroleum at 267,400,000 barrels, 2000 barrels more than in 1914. "This," says the statement, "does not agree with the currently reported reason for the exceptionally high prices now prevailing for motor fuel. As a result of the overload put on the transporting and refining phases of the petroleum industry by the excess output of 1914, the year 1915 may be characterized as a period of readjustment, in which production activity was purposely retarded as far as practicable. The small increase, therefore, is more significant than the simple figures indicate."

Factors that might be expected to affect the price of gasoline, according to the survey officials, are production, consumption and prices of crude petroleum. Consumption figures, they said, were not available, though consumption was increasing. A low petroleum price level was reached in April and until August the price remained at $1.35 a barrel for the market standard. Then the price began to soar, and on Dec. 17 petroleum was selling at $2.15. Indications now are, says the statement, that the price soon will reach $2.50, its previous high record.

Reserve of 220,000,000 Barrels

One production fact brought out by the survey is that crude petroleum stocks held in reserve, the largest ever known, increased 50,000,000 barrels in 1915, and at present more than 220,000,000 barrels are being held. Field storage by producers accounts for 24,000,000 barrels of this.

Export figures for the first ten months of 1915 show that gasoline exports dropped far below the same period in 1914, and slightly below 1913. During the ten months ended with October last 98,471,466 barrels left the United States against 140,275,273 barrels for the same period of 1914 and 100,353,871 barrels for 1913.

The relation between the cost of crude petroleum and gasoline is hard to determine, according to officials who have given the subject study, because of the varying grades of petroleum and the variety of oils produced in refinement. An increased demand for gasoline, they say, means an increased production of kerosene, lubricating oils and other petroleum products. All petroleum products have risen in price.

Rittman Process Influence

Officials familiar with the situation say the recent discovery of Dr. Walter F. Rittman, a government chemist, of a process for obtaining from crude oils 200 per cent more gasoline than by old methods, probably will have a bearing on both production and price before another year had passed. Several companies already have started production under the new method. Their output, and the output of others to be started, it was said, would be felt soon on the market.

In connection with the gasoline question some interesting facts have been developed by Judson C. Welliver, of this city, who is an authority. Some points brought out in an interview with Mr. Welliver are of interest at this time. "The government's big investigation of the whole petroleum products situation in this country has thus far tended to increase the mystery about tendencies in the oil business," said Welliver. "Less than three years ago authorities on oil matters were diligently predicting that conditions, which were then thoroughly bad, were going to be worse. The refiners in the midcontinent field were pictured as practically all losing money with every indication that they were going to lose more or else be forced out of business.

"Despite this gloomy forecast the price of gasoline is now high and mounting higher. There has been prophecy lately that it would soon reach 25 cents the gallon, and might get to 35 at no distant period. The investigators want to know why; and they are not finding out very fast.

War Affected Supply Little

"One part of the explanation, which occurs promptly to the inquirer, is that the war has created a huge, unexpected demand. I asked one of the government authorities, and he declared that he did not consider this true. While detailed figures on export of petroleum products as affected by the war had not been studied, it was doubted if, in fact, any more gasoline had been sold since the war began than before. The explanation was that for a considerable time after war started the oil steamships, which were largely sailed under the British flag, were off the seas; there were too many German cruisers turning up in unexpected places. By the time these commerce destroyers were cleared away, a big volume of sales had been lost. Since then the Allies have been taking large quantities of gasoline, but they have not been able to take as much as they wanted, because there were not ships to handle it. Some of the midcontinent refiners have recently been quoted as saying that they could send several times as much gasoline abroad if they could get ships to carry it. Moreover, the big Austro-German market has been cut off entirely from commerce in the fuel in recent time.

Seeking Other Causes

"So the investigators are seeking other causes for the increase in gasoline's price. Among the possible causes is the fact that production in the great Cushing, Okla., field is beginning to diminish. This was the greatest oil field ever opened in the world. It turns out a very high grade of crude oil for gasoline purposes; so good, in fact, that refiners in other sections of the midcontinent field found themselves under necessity of extending pipe lines to Cushing or using great numbers of tank cars in order to supply themselves with this high-class crude. The business got adjusted to the notion of making Cushing oil the basis, and now that the production there is falling off it is suspected that there is difficulty readjusting."

Avery to Make Tractor at $295

PEORIA, ILL., Jan. 2—The Avery Farm Implement Co. has decided to add tractors to its line, and equipment has been installed to produce a new model which is to be placed upon the market this year for $295, the lowest price ever quoted for a farm tractor. Models were shown during the past fall at the leading fairs and implement shows of the United States and orders have been received for 800. It is planned to manufacture several thousand during the coming year. The new tractor displaces four horses, and in addition, can be belted to any farm machinery, developing 10 hp. when used as an engine. It will pull two plows of 12-in. width at a depth of 6 in. in ordinary stubble ground; a 6-ft. disk harrow over plowed ground; a four section spike tooth harrow over plowed ground; a grain drill; a road drag; two loaded farm wagons; or anything else upon the farm that requires four horses to move. It will also operate a silo filler or feed grinder or any other farm implements of the present day.

May Examine Mass. Motorists

BOSTON, MASS., Jan. 1—The Safety First propaganda is to be carried before the Legislature this year according to plans now being formed, and it is possible that all future motorists in Massachusetts may have to pass an examination. Secretary of State Langtry has filed a report with the Highway Commission urging the appointment of from 1000 to 1500 persons, motorists as well as non-motorists, to act as monitors throughout the State. They would be given a badge by the commission, and authorized to warn drivers seen operating recklessly, and also report them to the commission. If a driver were reported two or three times by different monitors that would be evidence enough to cause a suspension of his license. The monitors would not have police power to make arrests.

The other movement has been started by the Highway Safety League. Its secretary, Lawrence G. Brooks, has filed with the incoming Legislature a bill calling for the examination of all motorists as follows:

> Section 1. Before granting a license to operate a motor vehicle the Highway Commission shall make an investigation into the mental, moral and physical qualifications of the applicant, such investigation to include a practical test of the applicant's ability to operate a motor vehicle and of his familiarity with the motor vehicle laws, and no license shall be issued until the commission or its authorized agent is satisfied that the applicant is a proper person to receive it. The foregoing provision shall only apply to applications for licenses made after the passage of this act.
>
> Section 2. All acts or parts of acts inconsistent herewith are hereby repealed.
>
> Section 3. This act shall take effect upon its passage.

$20 Fine for Jaywalking

On top of this Boston has put into effect its ordinance compelling all pedestrians to cross the streets at cross-walks where police officers direct traffic, and there is a penalty of $20 for crossing when the officer has signaled to vehicles to proceed.

Porter With Smith Form-a-Truck

CHICAGO, ILL., Jan. 3—Samuel D. Porter has been appointed general sales manager for the Smith Form-a-Truck Co., this city.

Overland Larger Four $55 Lower

Quantity Production and Abundant Material Permits Reduction from $750 to $695

TOLEDO, OHIO, Jan. 4—The Willys-Overland company has reduced the price of its larger four-cylinder Overland car $55, or from $750 to $695. It is stated that this reduction is made possible by the foresight of President Willys of the Overland organization in purchasing materials before war sent prices soaring. As an example of the economy effected as compared with present prices of these materials, the company has been able to save $3,500,000 on aluminum alone, while the savings on steel and other raw materials is in proportion. Quantity production is another factor in the reduced price of this model 83-B, large factory additions recently completed having enabled the company to more than treble its output of a year ago.

More than 50,000 cars of this model have been sold in all parts of the world since June, breaking all Overland sales records, more cars having been delivered in the past few months than in any previous year of the company's history.

Federal Truck Announces 2-Tonner at $2,100

DETROIT, MICH., Dec. 31—The Federal Motor Truck Co. has brought out a new 2-ton model. This was made necessary owing to the increasing demand from Federal distributors for a truck having a greater carrying capacity than 1½ tons and yet less than the 3½-ton truck which the company is making. Many business houses have been inquiring for such a medium model.

The price of the new truck is $2,100. It will be optional with the purchaser to have his truck with either a wheelbase of 144 in. or of 168 in. The motor is a Continental 4⅛ by 5¼. The ignition is single, the Eisemann being used. The gearset is of the selective sliding gear type. The axle is of the floating type. Springs are semi-elliptic. The front solid tires are 36 by 4 in., the rear tires 36 by 6 single or 36 by 4 dual.

Lewis, of Mitchell-Lewis, Dies

RACINE, WIS., Dec. 30—William Turnor Lewis, second vice-president of the Mitchell-Lewis Motor Co., Racine, Wis., one of the founders and principal stockholders in the concern, died suddenly on Dec. 30 at his home, from apoplexy. Mr. Lewis was born in Utica, N. Y., on March 10, 1840. His first occupation was that of a telegrapher. Mr. Lewis served through the Civil War as a military operator. In 1864 he married Mary Mitchell, daughter of Henry Mitchell, the first wagon manufacturer in the Northwest and founder of the business which in later years became the $10,000,000 Mitchell-Lewis Motor Co. When the present concern was organized, Mr. Lewis preferred to take a post of lesser importance and made his son, Capt. Wm. Mitchell Lewis, president. However, Mr. Lewis took an active interest in the affairs of the company until the day of his death. He served two terms as a State Senator and once was a popular choice for the nomination for United States Senator from Wisconsin. He is survived by a son, Captain Lewis, two daughters, and the widow.

Kentucky Wagon to Assemble Cars for Dixie Co.

LOUISVILLE, KY., Jan. 1—At a special meeting held Friday, a contract whereby the Kentucky Wagon Manufacturing Co. will assemble automobiles for the Dixie Motor Car Co., a concern in process of organization, for a period of 5 years, was approved by the stockholders.

The proposed concern will pay the wagon company a stipulated sum to assemble the cars and manufacture certain parts. R. V. Board, president of the wagon company, will be president of the wagon company's new enterprise. He announced to the wagon works' shareholders at Friday's meeting that they would be privileged to subscribe to stock in the automobile company on a pro rata basis.

2000 Moline Tractors for 1916

MOLINE, ILL., Jan. 2—The Moline, Ill., Plow Co. will, during the coming year, manufacture 2000 farm plow tractors. The two-plow tractor with plows of 12 and 14 in. in width, will be specialized, as this style has the advantage of being able to make a very short turn at the end of each furrow. The price has been fixed at $750.

Ford Tractor Plant for Canada

FORD CITY, ONT., Jan. 4—The Ford Motor Co. of Canada has purchased a site for the erection of a tractor manufacturing plant. Mr. McGregor is manager.

Trumbull Receiver Appointed

BRIDGEPORT, CONN., Dec. 31—Attorney E. K. Nicholson of this city, has been appointed temporary receiver of the Trumbull Motor Car Co., this city, with a bond of $25,000. At a stockholders' meeting recently it was voted to discontinue the business of the concern and the officers asked for the appointment of a temporary receiver.

S.A.E. General Meeting Modifies Headlight Resolution

All New Standards Passed—Small Attendance at Business Session—Constitution of Nominations Committee Discussed

NEW YORK CITY, Jan. 5—The business session of the S. A. E. opened this morning at 10.30, an hour later than scheduled. The business was mainly of a formal character, including the election of officers for the session 1916-1917, the acceptance of the treasurer's report, and passing of the general meeting upon the new standard resolutions passed the day previous by the standards committee and the council.

All these standards resolutions are reported on pages 19 to 23 and every one was accepted by the general assembly with the exception of the headlight resolution, which was modified a good deal.

Headlight Resolution Modified

On the presentation of the report of the electrical equipment division, the chairman, A. L. Riker, who had been absent from the standards committee meeting on Tuesday on account of sickness, stated that he personally did not agree with the resolution propounded by his division. His idea was that it was too sweeping and outside the province of the society. He said he did not think the society should go into legal questions but should confine its attention to engineering matters. President VanDervoort, speaking from the chair, said that he thought the subject ought to be discussed very fully indeed as it was of such great importance, and indicated that his own feeling was not entirely in accord with the resolution as passed by the standards committee and quoted on page 21 of this issue.

Hot Discussion Follows

The discussion following Chairman Riker's announcement was one of the most vigorous ever heard. It was very long, occupying most of the morning, and the final result was that the resolution was cut down so as to read:

> "The Division suggests as recommended practice the following, as a standard provision for the regulation of headlight illumination.
>
> "The headlights shall be so arranged that no portion of the reflected beam of light, when measured 75 ft. or more ahead of the lamps, shall rise above 42 in. above the level surface on which the vehicle stands."

It will be observed that this amended resolution confines itself to what the lamps shall *not* do and omits all reference as to what they *shall* do.

In the discussion the many speakers changed their exact opinions a good deal as the discussion progressed, but the apparent main reasons for the action taken were two in number. First, it was pointed out by several speakers, that electric cars and trucks, especially the latter, very seldom had lamps that would illuminate the road 150 ft. ahead of the vehicle, and that the recommendation as it stood would compel the purchase of new lamps by a great many users of automobiles, should it be adopted for legislative purposes.

Secondly, there was a fairly strong feeling evident that the subject was a dangerous one, that the S. A. E. might find the result of standing back of such a resolution extremely troublesome. In other words that it would involve taking part in activities outside the proper sphere of the society.

Innumerable Angles

Nearly every speaker had a different viewpoint. K. W. Zimmerschied, chairman of the standards committee pleaded for the resolution as it stood originally, saying that the present legal restrictions in different parts of the country are such that no one headlight can comply with them all. That it was essential someone should set up a definite guiding rule for legislators. He preferred the original resolution, but would sooner have it as amended by Mr. Riker than have it referred back to the division. In this view Mr. Zimmerschied was supported by a few, notably B. B. Bachman who, as a man vitally interested in the running of trucks went on record to the effect that illumination of a thorough character was essential to the safe operation of any sort of vehicle.

It was stated that the electric passenger cars were among the worst offenders on the glare question despite the fact that their light was not good from the driver's viewpoint. The president added a comment that it would seem to be difficult to compel a man to have so much light, in many cities all the law enjoined was that there should be a white light on either side to render the approach of the vehicle visible to another road user.

This led to a side discussion as to whether or not a *sufficiency* of light for safe driving ought or ought not to be a subject of legislative activity.

Finally on being put to the vote Mr. Riker's amendment was accepted, and will go through the mails to the full membership.

Nomination System Discussed

Under the head of "new business" W. H. Conant proposed that the method of selecting members for the committee upon which devolves the nomination of officers should be changed. At present the committee has seven members and the idea is that they shall be truly representative of the industry. Mr. Conant held the view that the present committee gave too strong a representation to certain sections and he suggested a new rule to the effect that each section of the society should select one member giving the minimum membership of the committee as five.

In discussion, which was vigorous, it was ascertained that only about half the total membership of the society is contained within the sections. So J. N. Heald proposed that the committee should consist of two nominees, not members of sections and a nominee from each section in addition.

The president said that the matter would have to be submitted to the whole membership by mail, sixty days before the summer meeting before anything could be done, so it was left to Mr. Heald and Mr. Conant to prepare written suggestions which could be dealt with in this way.

New Members of Council

As usual every nominee was accepted, for the new officers and councilmen, Russell Huff becoming president, with vice-presidents Eugene S. Foljambe and Robert H. Combs. Members of council to serve one year are David Beecroft, Directing Editor THE AUTOMOBILE, Edwin R. Hall, Goodyear Tire & Rubber Co., and John G. Utz, Perfection Spring Co. To serve one year on the council, George W. Dunham, consulting engineer. For treasurer, Herbert Chase was chosen.

New U. H. Klaxon Horn at $12

NEW YORK CITY, Jan. 4—A new motor-driven horn styled U. H. Klaxon, has been brought out for $12 by the Lovell-

McConnell Mfg. Co., Newark, N. J. It resembles the Klaxonet in shape but is longer and in that the motor shaft is horizontal and carried in a housing directly back of the horn bell. This motor drives a cam with many teeth cut on it, which vibrates the diaphragm and thus produces the sound.

It operates on 6 volts and is finished in black, which is the standard finish for the coming year. The other models will be continued. These include the Klaxonet, $15; U. H. Klaxet, $6; and the Klaxon, $20.

Promotions for Three Goodyear Men

AKRON, OHIO, Dec. 31—At the annual meeting of the Goodyear Tire & Rubber Co., Akron, Ohio, the promotion of secretary G. M. Stadelman, who has been sales manager throughout the Goodyear up-building, to a vice-president. He continues as sales manager.

P. W. Litchfield, who has been with Goodyear as factory manager almost since the beginning, was also elected a vice-president. A. F. Osterloh was elected secretary. He is also assistant sales manager.

233,325 N. Y. Cars Registered

ALBANY, N. Y., Jan. 4—Receipts aggregating $1,905,153 are reported by the Automobile Bureau for the eleven months ending Dec. 31, 1915. The whole of 1914 totaled only $1,618,060.

For the eleven months a total of 233,325 automobiles had been registered by owners or dealers—231,126 by the former and 2199 by the latter. During the same months in 1914 a total of 169,966 cars were registered, or 61,160 less than this year; dealers numbered 1743 and owners 168,223.

There were 101,074 cars registered in the New York City district up to Jan. 1, 1916; 72,815 cars were registered in the Buffalo district, and 57,237 in the Albany district.

Springfield Metal Body Detroit Plant Ready by March 1

NEW YORK CITY, Jan. 1—The Detroit plant of the Springfield Metal Body Co. will be ready for occupancy between Feb. 15 and March 1. This plant is somewhat smaller in area than the other one, in Springfield, Mass. There is a possibility that the main office may be in Detroit, but as yet nothing has been settled in regard thereto.

Middleton Steel Products Representative

DETROIT, MICH., Dec. 31—Ray T. Middleton will be Michigan representative and manager of the local branch of the Steel Products Co., Cleveland, beginning Jan. 1. Headquarters have been opened in the Ford building.

Freight Car Shortage Again Acute

N. A. C. C. Announces 15,582 Carloads Shipped in Dec., an Increase of 144 Per Cent

NEW YORK CITY, Jan. 5—That the freight car situation has again become acute is brought to light by the report of the traffic committee of the National Automobile Chamber of Commerce submitted at the annual meeting to-day. The shipments of automobiles for the month of December amounted to 15,582 carloads. This is an increase of 144 per cent over the same month of last year when 6378 were shipped. The number of freight cars for automobiles now in service is 59,274 and these will shortly be increased by 10,000 as the New York Central will soon put on 9000 more freight cars and the Pennsylvania road 1000.

The traffic department of the Chamber of Commerce intends to have representatives visit all centers to confer with the local traffic organizations for the purpose of securing co-operation. The traffic department is also in correspondence with every railroad for the purpose of securing more cars and impressing on the freight departments the necessity for quick return of the unloaded cars to the proper terminals.

Besides the routine business taken up at the meeting to-day, the Chamber has approved the recommendations of the Society of Automobile Engineers on standardization of methods of numbering motors, the uniform license plate and the proposed anti-glare headlight ordinance. These matters are at present before the S. A. E. for adoption and the approval of the N. A. C. C. will undoubtedly carry considerable weight.

Percy Owen Retires from Active Service With Saxon

DETROIT, MICH., Dec. 31—Although remaining as a director of the Saxon Motor Car Co., of which he was one of the organizers, Percy Owen has retired from all active service according to an announcement made by officials of the Saxon company. Mr. Owen had been giving special attention to all matters pertaining to the sales of the company.

Motor & Accessory Manufacturers Meet

NEW YORK CITY, Jan. 5—A meeting of the Motor & Accessory Manufacturers' Assn., was held in this city to-day at the Waldorf-Astoria where action was taken in regard to the election of four new directors to succeed the four retiring as follows: F. Hallett Lovell, Jr., C. E. Thompson, Alfred P. Sloan, Jr., and C. E. Whitney. About 100 members were present at the meeting. The four directors are elected for three years.

President Lovell's report showed that there are 241 members in the association. C. W. Stiger, chairman of the finance committee and J. S. Marvin, of the traffic department, made reports.

To-morrow the association will meet at its offices to elect officers. The present officers are: President, F. Hallett Lovell, Jr.; vice-president, C. A. Stiger; second vice-president, C. E. Thompson; third vice-president, T. J. Wetzel; treasurer, L. M. Wainwright, and secretary and assistant treasurer, A. P. Sloan, Jr.

General Motors Common Pays 20 Per Cent

NEW YORK CITY, Jan. 5—At to-day's meeting of the board of directors of the General Motors Co. the main issue on which action was taken was the placing of the common stock on a regular dividend basis of 20 per cent yearly. L. G. Kaufman, president of the Chatham & Phoenix National Bank, this city, was elected chairman of the board to succeed Emory W. Clark of Detroit, who was re-elected to that capacity at the annual meeting on Nov. 16. In confirming the decision as to dividends Mr. Kaufman refused to make any statement as to the affairs of either the General Motors or Chevrolet interests.

Ross & Young Machine Capital Now $750,000

DETROIT, MICH., Jan. 4—The Ross & Young Machine Co., established in 1910 with a capital stock of $35,000 has increased its capital to $750,000. This company also operates and controls the Ross Automobile Co., which incorporated in July, and is capitalized at $300,000. The latter company is bringing out a new model eight this year and is now making arrangements for a large production. The new Ross is to be shown in Chicago in connection with the annual automobile show.

Fitzsimmons Steel Products Breaks Ground

MILWAUKEE, WIS., Jan. 2—The Fitzsimmons Steel Products Co., which is the Wisconsin interest of the Fitzsimmons Steel & Iron Co., Chicago, Ill., has broken ground for a new steel finishing mill and power house in the Menomonee Valley at Milwaukee, Wis. The plant will be used exclusively for the production of cold drawn steel products. The factory will be 105 by 200 ft. on a site 200 by 275 ft. fronting both on the canal and the railroad tracks. Carl and Ernst Prinz of Milwaukee are among the principal stockholders

$4,000,000 Co. May Take Grant

Detroit and Chicago Interests Forming Corporation—Syndicate to Market Stock

DETROIT, MICH., Jan. 3—Andrews & Co., of this city and Chicago, and Livingstone & Co. are interested in a new corporation now being formed with a capital stock of $4,000,000 to take over the business of the Grant Motor Co., Findlay, Ohio.

These brokers will take $1,000,000 in preferred stock and $2,000,000 in common stock. The balance of $1,000,000 of common stock is to be held to exchange it for the preferred stock.

A syndicate is now being formed by the purchasers for the purpose of underwriting $1,000,000 preferred and $600,000 common stock and place it on the market. The preferred stock, which will pay 7 per cent dividends, is to be convertible into common at the option of the stockholder, prior to Jan. 1, 1919. After that time it will be redeemable at 120 plus the accrued dividends.

The present capital stock of the Grant Motor Co., which was organized in 1913, is $200,000. This is double the original capitalization.

Rockwell-Drake to Make Ball Bearings—May Remove to Plainville

HARTFORD, CONN., Jan. 1—It is admitted by Hugh Rockwell and L. A. Drake of the recently organized Rockwell-Drake Corp., which, among other things, is to make ball bearings, will remove to some location other than that at 78 Grove Street in Hartford. Because of this fact, coupled with the knowledge that A. F. Rockwell, late of the New Departure Manufacturing Co., and father of the younger Rockwell, acquired a site in Plainville, it is assumed the firm will locate there. The members of the firm are non-committal on the subject and the senior Rockwell says he is not interested. Messrs. Rockwell and Drake were formerly with the New Departure Manufacturing Co.

Martin Rocking Fifth Wheel Co. Organized in Springfield

SPRINGFIELD, MASS., Dec. 31—The Martin Rocking Fifth Wheel Co. has taken over the business and the patent rights of C. H. Martin, this city. The officers of the new corporation are C. H. Martin, president, Adolf A. Geisel, treasurer and H. G. Farr, secretary. Mr. Geisel, who will have the general management of the business, has been connected with the automobile industry for the past fifteen years.

The tractor-semi-trailer business had grown to the point where it was necessary to take in additional capital in order to supply the fifth wheel connections as fast as they were ordered. In addition to making fifth wheels in different sizes—from one that makes a Ford roadster into a 1-ton tractor to one that makes a 5-ton truck into a 10-ton tractor—the new company plans to make semi-trailers for the Ford size.

Pfau Mfg. Co. Enters Field

CINCINNATI, OHIO, Jan. 1—The Pfau Mfg. Co., this city, which has been engaged in the manufacture of brass goods in this city for the last twenty-five years, will expand this department to enter the automobile field. The company will be prepared to furnish to the trade large quantities of brass specialties. The company is in a position to duplicate any articles of brass tube and rod, or stamped products of sheet steel, iron, copper or brass. It is not the intention to manufacture large sheet metal parts like hoods, fenders, etc., but to make small and medium-sized specialties for manufacturers of automobiles, and also for those engaged in the manufacture of automobile accessories such as radiators, gasoline tanks, etc.

Detroit Steel Products Co.'s Production Increased Sevenfold

DETROIT, MICH., Jan. 1—The automobile spring plant of the Detroit Steel Products Co. is now in a position to handle about seven times as much production as a year ago. Production increases throughout 1915 were marked, averaging 43 per cent in February, 30 per cent for May and 25 per cent for June, and 24 per cent in August. November production was held up slightly because of inability to obtain sufficient steel, but it is expected that December's production will have increased sevenfold over January's record.

Simplex Plant to Be Enlarged

NEW BRUNSWICK, N. J., Jan. 2—The plants of the Simplex Automobile Co., this city, are being materially enlarged for the manufacture of aeroplane motors on designs and under the patents of the French motor which representatives of the company have secured in France through the assistance of the French government. The motors, which are being made for the Wright Aeroplane Co., will be made under license, free of charge.

Contracts for the construction of additional buildings at the Simplex plant to cost $300,000 have already been let and more than $200,000 worth of new machinery has been ordered. It is planned to increase the output of the Simplex plant to 100 motors a day.

A. B. C. Starter Co. Formed

C. P. Sieder, Alexander Churchward and B. S. Colburn, Incorporators

NEW YORK CITY, Jan. 4—The A. B. C. Starter Co. has been incorporated in Michigan for $150,000 by Charles P. Sieder, Alexander Churchward and B. S. Colburn. Mr. Sieder is president and general manager; Mr. Churchward, vice-president and chief engineer, and Mr. Colburn, secretary and treasurer. The company will manufacture a lighting and starting system adaptable to Ford cars. The system is of Mr. Churchward's design and has independent units for starting and lighting. The entire outfit, according to Mr. Churchward, will weigh less than 100 lb. and will be on exhibition at the Ward Leonard booth at the Grand Central Palace show before the end of the week.

The starting motor is series wound and provided with a Bendix gear. It will have 150 lb. stalling torque and is fitted with a Bendix drive geared 14 to 1 to the flywheel. The generator is driven from the same belt as drives the fan, this being a patented feature. The generator is a slow-speed machine and its ratio to the crankshaft is 1¼ to 1. The generator cuts in at 8 m.p.h. and carries a full lamp load at 10 m.p.h. It is designed to operate in conjunction with a 6-volt, 60-amp. battery, and is fitted with the Ward Leonard magnetic regulating system.

American Rotary Valve Discontinues Electric Motors

ANDERSON, IND., Jan. 1—The American Rotary Valve Co., this city, announces that, due to the development of business on the Arvac universal joint, which it manufactures, and to which the company will now devote its entire effort, the manufacture of electric motors, press drives and its present line of vacuum cleaners will be discontinued. It will fill orders at present in hand, and continue to provide repair service on all these lines.

New Factory for S. K. F.

HARTFORD, CONN., Jan. 1—A permit to build a factory of brick, one and two stories to cost $150,000 has been issued to the S. K. F. Ball Bearing Co. The building is to be 180 by 200 ft.

Piston Ring Co. Expands

MUSKEGON, MICH., Dec. 29—Twelve lots have recently been purchased by the Piston Ring Co. and the company will put up a new large building, 125 by 180 ft., which will more than double the present factory capacity. Between 100 and 150 more men will be added to the working force. The new building will cost about $20,000 and about as much will be spent for additional equipment and machinery. At the present time day and night shifts are working and the company has more orders than at any other time since it started in business.

It is said that president Charles E. Johnson of the Piston Ring Co. will back a new company now being formed and which will make automobile parts. This concern's business will not interfere with that of the piston ring company.

American Tire Fabric Co. Formed, Capital $1,500,000

BOSTON, MASS., Dec. 31—The American Tire Fabric Co. of Boston and New York has organized under Massachusetts laws with an authorized capital of $1,500,000, consisting of 35,000 first preferred, 65,000 second preferred and 50,000 common, all of $100 par value. The purpose of the company is to manufacture, buy and sell cotton, yarn and other textile fabrics.

Auto Parts Co. Reorganizes and Absorbs Badger Specialties

MILWAUKEE, WIS., Jan. 3—The Auto Parts Mfg. Co., 528-532 Broadway, Milwaukee, has effected a reorganization and absorbed the Badger Specialties Mfg. Co., also engaged in the manufacture of accessories, sundries, parts, etc. Andreas M. Soennichsen recently retired from the company to organize the A. M. S. Mfg. Co. The active management of the Auto Parts company is now in the hands of W. N. Schwab, general manager; C. W. Beckler, sales and advertising manager, and F. B. Sykes, factory manager. B. L. Hibbard is president of the company and the other directors are: P. D. Durant, T. J. Pringle, J. D. Millar, H. Nauman, Charles Thompson, E. O. Ellsworth and William Lindsay.

$1,000,000 Goodyear Plant for Canada

NEW TORONTO, ONT., Jan. 3—Arrangements are being made by the Goodyear Tire & Rubber Co., Akron, Ohio, to establish a Canadian plant at New Toronto. A by-law will be shortly submitted to the ratepayers to grant a fixed assessment of $1,000 an acre on the 27 acres to be used for the plant. The Goodyear people have agreed to spend $1,000,000 on the plant.

Rock Hill Co. Makes Ford Bodies

ROCK HILL, S. C., Dec. 31—The Rock Hill Buggy Co., this city, is building standard commercial bodies for the Ford chassis in quantities.

12,000,000 Champion Plugs in 1916

Annual Convention Held at Factory Attended by Complete Sales Organization

TOLEDO, OHIO, Dec. 30.—The annual sales convention of the Champion Spark Plug Co. was brought to a close here yesterday. The complete sales organization, which since 1913 has grown from three to twenty-six members, being in attendance during the three days of the convention. Full details of the company's policies during the present year were discussed and from the enthusiasm at the various meetings, it seems likely that the output of 12,000,000 spark plugs for 1916 will be more than sold. Among those present were: D. M. Barrett, editor of Salesmanship; Henry Paine, general attorney; Harry Harper, sales manager; Willys-Overland Co.; Wilbur Owen, Champion Spark Plug Co. patent attorney; M. DeWitt, president, J-D Co.; President R. A. Stranahan, Advertising Manager H. L. Corey, Treasurer F. D. Stranahan, Sales Manager F. D. Caswell, Purchasing Agent J. F. Barr, H. W. Biddle, C. B. Clark, J. T. Moultroup, George French, Jr., Charles Corwin, H. A. Kaiser, E. M. Stern, W. F. Minnich, H. C. Thanasse, W. J. Shay, C. L. Ughetti, K. Latta, H. MacLaren, Harold E. Butcher, E. H. Blackwell, H. A. Krause, E. C. McKinney, R. C. Parrish, J. B. Cox, H. A. Houston, O. C. Rohe, Charles DeWar.

Goodyear Gives Insurance Policies to Employees

AKRON, OHIO, Dec. 31—The Goodyear Tire & Rubber Co. will give its employees an insurance policy for $1,000, free of all cost, provided the employee is or becomes a member of the Goodyear Relief Assn., which provides sick and disability insurance. Under its new plan it establishes retirement awards, and also a group insurance plan. The retirement awards make provision for stated monthly payments for life to men who have reached the age of seventy and women who have reached sixty-five, and there is also a condition under which old employees may retire, with awards, under the age limits mentioned.

Robbins & Myers Gives Insurance Policy to Each Employee

SPRINGFIELD, OHIO, Dec. 31—The Robbins & Myers Co., this city, manufacturer of electric motors, generators, etc., handed an announcement to each of its employees on Thursday, Dec. 23, to the effect that a life insurance policy had been taken out by the company for every employee. The policy is paid for by the company and all premiums are paid as long as the employee is connected with the concern. The amount of the policy increases with the length of time of the employee's service, as follows:

One year or less	$500
One year and under two	600
Two years and under three	700
Three years and under four	800
Four years and under five	900
Five years and over	1,000

Jeffery Gift of $40,000 to Employees

KENOSHA, WIS., Jan. 2—The largest distribution of profits to employees ever made by a Kenosha concern was the gift of $40,000 to the 3000 operatives in the plants of the Thomas B. Jeffery Co., Kenosha, Wis., in connection with the weekly pay-roll on Dec. 27. The regular pay-roll amounted to $60,000, making a total distribution of in excess of $100,000. A full week's pay was given to each of the 2700 employees working for the company on June 1, 1915, and one-half week's pay to the 300 employees who have been with the concern since that time.

Harper's Latest Trailer

SOUTH BEND, IND., Dec. 31—The Harper Buggy Co., Columbia City, Ind., is manufacturing a trailer of 1500 lb. capacity, arranged to be attached to a motor vehicle by means of a universal joint connection.

Hudson Gives Christmas Presents

DETROIT, MICH., Dec. 30—The Christmas gift of the Hudson Motor Car Co. to those of its factory workers on the payroll six months or longer was a week's wages, while all office employees with the company one year or longer also received an extra week's pay. It is said that over 700 employees came within these regulations and that about $20,000 was involved.

Dort Employees Receive Present

FLINT, MICH., Dec. 24—The Christmas present of the Dort Motor Car Co., and the Durant-Dort Carriage Co., to their employees, was in the shape of $300 which has been deposited with the Flint Vehicle Factories Mutual Benefit Assn. The money is to be credited upon the insurance accounts of all the employees of both concerns.

Cash Gift for Bowser Employees

FORT WAYNE, IND., Jan. 1—All employees of the Bowser Tank & Pump Works, this city, received a cash Christmas gift from the company when between $6,000 and $7,000 were given directly or sent to the 1700 persons connected with the institution. The gifts were from $2 to $5 each.

New Finance Plan for S. R. B.

Assessment of $730,713 to Reduce Debt and Capital $1,908,077

PHILADELPHIA, PA., Jan. 2—Stockholders and creditors of the Standard Roller Bearing Co., this city, have been presented with a plan for the refinancing of the company. The company proposes to make an assessment of $730,713 on stockholders, and .to reduce the debt and capital from $5,799,835 to $3,891,758, with further provisions that the holders of notes and other payable accounts are to be offered the alternative of 60 per cent of their claims in cash as payment of debts in full, or 80 per cent of their claims in the shape of redeemable income certificates covering a period of twenty years. The assessment will be made on the basis of $15 per share of first preferred, in return for which the holders will receive 7 per cent new preferred and 50 per cent of the present holdings in new common stock. Second preferred will be assessed $7.50 per share, in return for which new preferred will be paid, in addition to 25 per cent of holdings in common stock. The assessment will also include common stockholders who will receive 20 per cent of their holdings in common stock.

Premier Motor Corp. Incorporated

DOVER, DEL., Dec. 30—The Premier Motor Corp. has been incorporated in this State with a capital of $2,000,000. The incorporators are: H. E. Latter, N. P. Coffin, C. M. Egner, all of Wilmington.

N. A. C. C. Book on Supervision of Automobile Equipment

NEW YORK CITY, Jan. 1—The traffic department of the N. A. C. C. and the Motor and Accessory Manufacturers has compiled a booklet to facilitate the return of automobiles sent by rail and to serve as a ready reference. This book has been distributed so that better supervision of automobile equipment will be made by the railroads over which approximately 140,000 carloads of automobiles were shipped in 1914. It is expected that shipments in 1915 will exceed 200,000 carloads.

Westcott Not in Indiana Merger

RICHMOND, IND., Jan. 2—The recent publication of a rumor that the Westcott Motor Car Co. is to enter a combination of Indiana automobile and parts companies has brought a vigorous denial from H. G. Root, general manager of the Westcott company. Mr. Root declares that the Westcott company will not enter the proposed merger and has not even been contemplating such action.

Morgan & Wright Add $600,000

DETROIT, MICH., Dec. 31—Morgan & Wright, this city, have increased their capital stock from $5,000,000 to $5,600,000. Approximately $500,000 of the new capital will be issued at once while the remainder will be held in reserve. It is said that plans are under way for increasing the expansion of facilities of the company which has been going on for some time.

Goodrich Directors Meet Jan. 26

AKRON, OHIO, Jan. 3—The directors of the B. F. Goodrich Co. will meet for action on the common dividend, Jan. 26.

Hupp Gains 25 Per Cent in Quarter

DETROIT, MICH., Dec. 30—During the last quarter of 1915, the production and sales of the Hupp Motor Car Co. were 26 per cent better than during October, November and December, 1914. Orders on the books now for immediate delivery are 100 per cent greater than at this time a year ago, according to Commercial Manager Lee Anderson.

Higher Prices for Materials

Para Rubber Reaches 96 Cents—Open-Hearth at $34 a Ton—Pa. Crude Rises to $2.25

NEW YORK CITY, Jan. 4—Steel, rubber, copper and lead prices last week reached new high marks. These four materials have seen a steady rise during the last few months. There is an unprecedented demand for these materials and it is expected that a further rise in prices will occur. Bessemer and open-hearth steel have reached $33 and $34 per ton, respectively. Sharp advances occurred in the crude rubber market both here and in London. Up-River fine was quoted at all the way from 93 cents to $1 a pound and first latex pale at $1.02 to $1.05. The rise of prices in rubber is at the present time of importance to the trade in general because of the pending general rise in tire prices. Copper last week rose from 21½ to 23 cents. The demand for copper continues large and sales at the high prices are limited. Lead was firm at $5.50 per 100 pounds.

An advance of 10 cents a barrel to $2.25 occurred last week in the price of Pennsylvania crude oil. Oil authorities expressed some hope that this latest rise would bring out stocks now in the hands of producers, which are badly needed by refineries because of the tremendous demand for oil for domestic and foreign use. As to what will develop with regard to the production of crude oil, nothing at the present time can be ascertained, but provided the ratio of decrease in supply to demand continues, the finding of a substitute for gasoline, it is said, will in the future be the only solution of the high price problem. Apropos of the present prices of gasoline, the question of using kerosene as a substitute for that fuel has been the cause of many experiments along that line. Europeans since the war have had their eyes opened to the adaptability of the American automobile engine to a low gravity gasoline. Some of the French makes of cars require 68 to 76 deg. gravity, whereas the American-made motors use 60 to 62 deg. gravity.

Ajax Elects Directors

NEW YORK CITY, Dec. 31—The following directors of the Ajax Rubber Co. have been elected: Horace De Lisser, W. G. Grieb, H. W. Stimson, J. C. Matlack, L. P. Destribats, R. A. Patterson, H. K. Pritchitt.

Autocar Dividend of 5 Per Cent

ARDMORE, PA., Dec. 31—The directors of the Autocar company, this city, have voted that a 5 per cent cash dividend be declared, payable to-day, to stockholders of record at the date of the meeting, the first cash dividend declared for a number of years. They also voted that $400,000 of their accumulated surplus be made permanent capital by issuing capital stock therefor. The capital of the company was increased on Oct. 14 from $1,000,000 to $2,000,000.

Lozier Motor Capital to Be $3,000,000?

DETROIT, MICH., Dec. 31—The Lozier Motor Co. has succeeded the Associated Lozier Purchasers, which was the name under which the purchasers of the assets of the old Lozier company had incorporated last year. It was stated at the offices of the Lozier company that the reorganized company will be incorporated some time in January and that the capital stock will be between $3,000,000 and $5,000,000.

Canadian Ford Dividend to Be Paid Jan. 8

FORD, ONT., Dec. 31—Stockholders of the Ford Motor Co. of Canada, Ltd., have been notified that the 600 per cent stock dividend recently declared will be paid to stockholders of record Jan. 8. From Jan. 8 to 12 the books of the company will be closed, and during that time old stock certificates must be surrendered.

Regular Dividends Declared

Packard Motor Car Co.; cash dividend of 1¾ per cent and stock dividend of 10 per cent on common, payable Feb. 1.

Kelly-Springfield Tire Co.; quarterly of 3 per cent on common, payable Feb. 1 to stock of Jan. 15.

Tire Stocks Are Higher

Firestone Common Rises 20 Points—Miller Rubber Common Shows 25-Point Gain

NEW YORK CITY, Jan. 4.—Activities in last week's securities were for the most part based on pre-dividend announcements. A number of the companies will hold directors' meetings this month to decide on dividends. A Goodrich meeting is scheduled for Jan. 26. It is expected in financial circles that a resumption of dividends on the common stock will be at a rate around 4 per cent. The Maxwell dividend on the first preferred disposes of the accumulation on the first preferred stock. The first preferred stock holders have the option to use their warrants in paying for new first preferred stock at par at any time on and after Jan. 3 and up to June 30, 1916. Ajax Rubber stockholders, it is stated, will not have to wait for dividends. During the present month the directors will declare the initial quarterly dividend of $1.25 a share on the new stock and dividends will be maintained regularly thereafter at the rate of $5 a share with frequent extra disbursements. This stock first appeared on the market several weeks ago at 65. It sold yesterday at 71¾.

The market yesterday showed strength under the test of evil news from the Mediterranean where much submarine warfare has been carried on lately. Much strength was shown in tire issues, especially in Miller Rubber, Firestone and Goodyear. Miller Rubber common went up 25 points, closing at 260; Firestone rose 20 points to 710, and Goodyear common went up 7 points to 342.

Maxwell first preferred closed Saturday at 92 and went up another point yesterday, making a gain of 11 points. Packard common went up 5 points and Peerless closed at 27 with a 7-point gain.

A number of the automobile stocks were lower last week. Reo Motor Car went down 35 points on the ex-dividend of 100 per cent. Willys-Overland common dropped 7 points to 232 and Studebaker common dropped 2½ points.

Quotations on the Detroit Exchange were lower, with the exception of General Motors common, which rose 32½ points to 460. Maxwell first preferred dropped 8½ points to 91, presumably on account of the payment of the dividend on that stock. Packard common closed at 185 with a 3-point loss. Studebaker common rose 2 points to 166½.

Recent Changes in Capitalization

FOSTORIA, OHIO, Dec. 31—The Allen Motor Co. has decreased its capital from $500,000 to $400,000.

AKRON, OHIO, Dec. 31—The Mohawk Rubber Co. has increased its capital from $250,000 to $500,000.

DETROIT, MICH., Dec. 31—Goodspeed-Detroit Mfg. Co., capital increased from $20,000 to $50,000.

NORTH DETROIT, MICH., Dec. 31—Russel Motor Axle Co., capital increased from $150,000 to $250,000.

DETROIT, MICH., Jan. 3—Morgan & Wright, capital stock increased from $5,000,000 to $5,600,000.

Boston Show Space Insufficient

May Have To Secure Another Hall—Chicago Show a Japanese Garden

Boston, Mass., Dec. 31—The officials of the Boston Automobile Dealers Association are faced with the alternative of either hiring an additional hall for the motor show or turning away applicants for space. At Boston a big share of space is taken by the truck dealers, and so that means the space that was available in the past when there were two distinct shows is allotted. Some of the passenger car men would like to have the trucks put in another hall, for they realize that to exhibit outside will hardly pay. The matter will be put up to the applicants and they can make the decision. If enough of them decide to go in the other hall will be engaged.

Chicago Show a Japanese Garden

New York City, Dec. 31—Samuel A. Miles, general manager of Chicago Automobile Show to be held in the Coliseum and Armory, Jan. 22-29, announces that the decoration scheme in the Coliseum will be in the form of a Japanese garden. This scheme will be carried out by covering the entire ceiling with Japanese kiosks, together with Japanese lamps, etc., throughout the building.

New Machinery for Duplex

Charlotte, Mich., Dec. 31—More machinery is being added to the equipment of the Duplex Power Car Co. Further enlargements of the plant are also contemplated. Business on hand will keep the plant running to full capacity well into the new year.

Indianapolis Entry Blanks Out

Indianapolis, Ind., Dec. 31—Entry blanks have been sent out for the 300-mile race to be held May 30 on the Indianapolis speedway. The purse for the race has been reduced from $50,000 to $30,000, the first prize $12,000. There will be ten prizes, the same as in former years.

New Cast-Steel Wheel

Syracuse, N. Y., Dec. 31—The Smith Wheel, Inc., of this city is shortly to produce a new form of cast-steel wheel especially for motor trucks. It is of the hollow one-piece type, with twelve spokes, like a wooden wheel, thus avoiding the odd appearance common to some steel wheels. Each spoke is a graceful smooth exterior oval, blending naturally with the felloe and hub. It is fitted with reinforcements in its cored-out interior and has no holes except the regular hub flange holes, which are standard, thus permitting the wheel to be interchangeable with standard wood wheels.

The wheel is made both for single and dual tires and is adapted to either pressed-on or demountable solid tires.

In tests it is claimed that the wheel was able to take a load of 30 tons in a horizontal direction before the wheel dished ¼ in., when with the pressure withdrawn, it sprang back into its normal shape. Individual spoke sections were also stressed up to 30 tons, it is stated, the wheel load being taken by six spokes three upper and three lower in practice.

Reo Refuses War Order for 1000 Motor Trucks

Lansing, Mich., Dec. 30—The Reo Motor Truck Co. was approached recently with regard to furnishing 1000 trucks to one of the European belligerent nations. R. C. Rueschaw, sales manager of the company, states that the order was not accepted because the Reo company is not looking for business from those countries at this time. The reason is that the domestic business of the Reo Motor Truck Co., has been increasing so rapidly that it has not been possible to take care of it as would have been desirable. To have accepted the foreign order would have been the cause of still greater disturbance in taking care of the American business.

A. C. A. Tests Four-in-One Heater

New York City, Jan. 3—The testing laboratory of the Automobile Club of America has made a series of tests to determine the effect of the Four-in-One heater, manufactured by the Continental Auto Heater Co., 18 E. Forty-first Street, New York, upon fuel consumption, power output and back pressure. It was found that while the power output and fuel consumption were unaffected, back pressure was reduced to a marked degree. With the heater valve open the back pressure was less than one-half of what it was without the heater attached, and with the heater valve closed the back pressure was less than without the heater in the line. The device is a radiator heated by exhaust gas.

Dann Inserts Cost Less

Chicago, Ill., Jan. 1—Dann cushion spring inserts have been reduced in price, sets formerly selling for $8 now being priced at $5.70 each.

Bosch Holds Annual Convention

New York City, Dec. 30—The Bosch Magneto Co. held its annual distributors' convention on Dec. 30, an all-day session being held in the offices of the company. After a morning session begun at 9.30, luncheon was served to the delegates at 1.00. Business was resumed after luncheon and the session continued until 7 o'clock. A banquet was served at Reisenweber's immediately afterward and the party disbanded to meet on Friday for a trip of inspection through the Springfield works.

Bosch Adds Eighteen Concerns

New York City, Jan. 1—The Bosch Magneto Co., this city, has signed contracts with eighteen concerns in the automobile and commercial vehicle fields to use Bosch magnetos for the coming season, making a total of 176 closed during the past season. The eighteen new contracts are as follows:

Nordyke & Marmon Co.	Indianapolis, Ind.
The Russell & Co.	Massillon, Ohio
Croce Automobile Co.	Asbury Park, N. J.
Bessemer Motor Truck Co.	Grove City, Pa.
Harwood-Barley Mfg. Co.	Marion, Ind.
Diamond T Motor Car Co.	Chicago, Ill.
Krebs Commercial Car Co.	Clyde, Ohio
D. F. Poyer Co.	Menominee, Mich.
Service Motor Truck Co.	Wabash, Ind.
J. D. Fate Co.	Plymouth, Ohio
The New-Way Motor Co.	Lansing, Mich.
Signal Motor Truck Company	Detroit, Mich.
Zeitler & Lamson	Chicago, Ill.
Walden W. Shaw Livery Co.	Chicago, Ill.
Winton Co.	Cleveland, Ohio
Transport Tractor Co.	Long Island City, N. Y.
Old Reliable Motor Truck Co.	Chicago, Ill.
Chester County Motor Co.	Coatesville, Pa.

Overland Factory Office for Seattle

Seattle, Wash., Jan. 1—The Willys-Overland Co. will establish a factory office in this city, controlling the territory of Washington, Oregon, Idaho, Montana and British Columbia. J. V. Hough will have charge of the office.

Cox Raises C-C Shock Absorber Price

New York City, Jan. 3—Increased cost of production due to improvements in design, material and workmanship are responsible for an increase in the price of the C-C heavy type shock absorber manufactured by the Cox Brass Mfg. Co., Albany, N. Y. The price is now $12 per set of four, as against the former price of $10 per set. The Ford type remains at $8 per set or $4.50 per pair.

Dinner Tendered to Kennerdell

New York City, Jan. 4—A complimentary dinner was tendered Richard Kennerdell last night at the Biltmore by President Wilson of the American Automobile Assn. and thirty of his associates on the contest board. Mr. Kennerdell was presented with a watch in recognition of his services as chairman of the committee.

Gets Crane-Simplex on Coast

New York City, Jan. 2—The Arnold-Stelling Co., Inc., has secured the Pacific Coast agency for the Crane model Simplex cars and will open representation in San Francisco at Hotel St. Francis, Feb. 1. A salesroom will be opened in March. In addition to the exclusive rights for the Pacific Coast, Arnold-Stelling have all territory west of the Mississippi which is open at present. Jan H. Stelling, president, has been sales manager of the DeDion in New York for eight years, and Geo. K. Arnold, secretary, has been connected with the business in New York.

—

Anderson Electric Managers Meet

DETROIT, MICH., Dec. 31—The first annual convention of branch managers and road men of the Anderson Electric Car Co. was held here this week. Those in attendance reported this to have been the biggest year in history for electric passenger cars while prospects for next year are very encouraging. The Anderson company is planning a greatly increased production for 1916.

—

Allen Banquet Celebrates Addition

FOSTORIA, OHIO, Jan. 3—By way of celebrating the completion of its new chassis assembly plant, the Allen Motor Co., last week entertained its employes and about 500 guests at a banquet. The new building increases the floorspace of the Allen company by 32,000 sq. ft. Following a program of entertainment, the gathering was addressed by E. W. Allen, who stated that the present capacity of the factory was eighteen cars per day and that this will be increased to fifty cars by March 1. Others who spoke at the gathering were S. M. Hopkins, W. O. Allen, Judge George Schroth and J. P. Hunting.

—

Eisemann Magnetos Exclusively on 1916 Pierce-Arrow Trucks

BUFFALO, N. Y., Dec. 31—For the coming year, the 3-ton Pierce-Arrow trucks will use exclusively Eisemann magneto type EM4 dual and Eisemann coil type DCR. The Pierce-Arrow 2-ton trucks will use exclusively Eisemann magneto waterproof type G4. Deliveries will begin in February.

—

White Adopts Eisemann Magneto

NEW YORK CITY, Jan. 1—The Eisemann Magneto Co. will begin deliveries in January on a contract made some months ago, of the Eisemann type G 4 magneto to the White Motor Co., Cleveland, Ohio, which has adopted this magneto as standard equipment for all its trucks.

—

Doehler Die Casting to Add

TOLEDO, OHIO, Dec. 31—The Doehler Die Casting Co. is planning to build factory structures estimated to cost $69,514. Three buildings are planned in the 1900 block, on Smead Avenue. All are to be of steel, concrete and brick. One building, estimated to cost $42,746.77 will consist of two stories and a basement, and will be 50 ft. wide by 260 ft. long. A new foundry will cost $8,922 and will be one story and a basement, 50 by 180 ft. The third building, a warehouse, 50 by 160 ft., will cost $17,844.82, and will be one story, with basement.

—

Toledo Machine Sold to N. Y. Interests

TOLEDO, OHIO, Dec. 31—The Toledo Machine & Tool Co. has been bought by Hoit, McWilliam & Co. of New York for clients. The company is capitalized at $6,000,000, the stock having been increased through the distribution of a 400 per cent stock dividend. The company has specialized in the manufacture of machinery for making sheet metal products.

—

Mich. Hearse & Motor Co. Reorganized

GRAND RAPIDS, MICH., Dec. 31—The Michigan Hearse & Motor Co. has been reorganized. Walter Ioor has been elected president, succeeding Alvah W. Brown. Mark Norris is vice-president; A. C. Chapman is secretary and sales manager and E. W. Aumeal, general manager. The factory has been enlarged through a three-story addition, 40 by 100 ft.

Proposed Eighth Report of Iron and Steel Division

(*Continued from page* 23)

(c) Tension and bend test specimens for plates and shapes shall be of the full thickness of material as rolled; and may be machined to the form and dimensions shown in Fig. 1 (see proof for sheet 15a of Vol. I of Handbook) or with both edges parallel.

(d) Tension and bend test specimens for rolled bars and forgings of uniform cross-section 1½ in. or less in thickness or diameter, may be of the full-size section of material as rolled or forged, or may be machined for a length of at least 9 in., in which case the gage length shall be 8 in. Tension test specimens should preferably be of the S. A. E. standard form as illustrated in Fig. 2 (See proof for sheet 15xa of Vol. I of Handbook).

(e) The axis of tension and bend test specimens for rolled bars and forgings of uniform cross-section over 1½ in. thickness or diameter, and for forgings of irregular sections, when practicable, shall be located at any point midway between the center and surface when solid, and at any point midway between the inner and outer surfaces of the wall when bored, and shall be parallel to the axis of the piece in the direction in which the metal is most drawn out. Tension test specimens shall be of the form and dimensions shown in Fig. 2. Bend test specimens shall be ½ in. square in section with corners rounded to a radius not over 1/16 in., and need not exceed 6 in. in length.

Number of Tests

13 (a) Unless otherwise specified by the purchaser, one tension and one bend test shall be made from each melt; except that if material rolled from one melt differs ⅜ in. or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded; in which case the manufacturer and the purchaser or his representative shall agree upon the selection of another specimen in its stead.

(c) If the percentage of elongation of any tension test specimen is less than that specified and any part of the fracture is more than ¾ in. from the center of the gage length of a 2 in. specimen or is outside the middle third of the gage length of an 8 in. specimen, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

Finish

14. The material shall be free from injurious defects and shall have a workmanlike finish.

Inspection and Rejection

Inspection

15. (a) The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered. The manufacturer shall afford the inspector, free of cost, all reasonable facilities to satisfy him that the material is being furnished in accordance with these specifications. Tests and inspection at the place of manufacture shall be made prior to shipment.

(b) The purchaser may make the tests to govern the acceptance or rejection of the material in his own laboratory or elsewhere. Such tests, however, shall be made at the expense of the purchaser.

(c) All tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

Rejection

(a) Unless otherwise specified, any rejection based on tests made in accordance with Section 15 (b) shall be reported within ten working days from the receipt of samples.

(b) Material which shows injurious defects while being finished by the purchaser will be rejected, and the manufacturer shall be notified.

Rehearing

17. Samples rejected in accordance with Section 15 (b) shall be preserved for one month from the date of the test report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

Regarding Specifications, and Notes and Instructions

The notes and instructions following the Specifications given above are not to be considered in any way a part of these Specifications. They are added solely for the information of the user of the steels and the guidance of the purchaser in the selection of proper materials for his different purposes. They should not be incorporated in the Specifications when ordering steel except under such conditions as are imposed in the Specifications themselves.

(End of Seventh Report Revision)

Standard Test Specimens

Shock Test

It is recommended that the 10 by 10 mm. test piece 40 mm. long with notch 2 mm. deep and 1 mm. wide be adopted as the standard specimen for shock test. The bottom of the notch is to be of 0.5 mm. radius, smooth and free from scratches. (See proof of sheet 15xb of Vol. I of Handbook).

Flat Tension Specimen

It is recommended that we adopt the standard flat strip test specimen of the American Society for Testing Materials. The gage width of specimens ¼ in. or less in thickness should be equal to five times the thickness, except that in no case shall the width be less than ¾ in. The gage length should equal twenty-four times the thickness of the specimen, except that in no case shall it be less than 2 in. (See proof of sheet 15xa of Vol. I. of Handbook).

It is recommended that our present flat tension test specimen be called recommended practice for use in cases where the standard specimen cannot be made. (See proof of sheet 15a of Vol. I of Handbook).

Alternating Stress Specimen

The removal of the present alternating stress test specimen (see sheet 15b of Vol. 1 of Handbook) from the list of standards is recommended as it is very little used in its present form.

Gray Iron Specimens

It is recommended that the A. S. T. M. gray iron specimens be adopted as standard of the S. A. E. (See sheet 15c of Vol. I of Handbook).

Finish on Standard Specimen

It is recommended that instructions be appended to the present standard 2 in. tension test specimen, calling for finished lapping or grinding of the gage length. (See proof of sheet 15 of Vol. I of Handbook).

Brinell Test

It is recommended that instructions for the Brinell test, based upon the recommended practice of the A. S. T. M. (See proof of sheet 15xd of Vol. I of Handbook) be published as the standard method of this Society.

"Temper" of Sheets and Tubing

A sub-committee constituted of Messrs. Johnson and Zimmerschied were appointed to investigate the advisability of establishing standard practice or nomenclature relating to the various "tempers" or physical conditions of sheet steel and seamless drawn tubing.

Standard Color

A sub-committee consisting of Messrs. Rys, Johnson and Trabold was appointed to investigate the feasibility of establishing a scale of standard colors for painting each of the various grades of S. A. E. carbon steels, it being recognized that the alloy steel grades are too numerous to lend themselves to a suffciently simple scheme of designation by colors.

Bakelite—A Synthetic Resin

(*Continued from page 36*)

pared in the form of a dry, granular powder or sometimes in thin, hard sheets which soften readily on being slightly heated so that they can be cut or otherwise manipulated for loading the dies.

The first application of heat and pressure applied to this material has the effect of momentarily softening it so that it fluxes freely, taking accurately the form of the mold. The continued application of heat and pressure brings about a chemical reaction which causes it rapidly to harden or "set," into a solid homogeneous mass, after which it cannot be softened again by further heating. The time of this "cure" will vary from 5 to 8 min., depending upon the size of the piece. The work comes finished from the die, excepting for a slight "fin" where the halves of the die come together, which has to be dressed off. Bakelite parts can be molded with great accuracy and will take a high molding finish. Metal inserts can also be readily molded in the material, which in many cases reduces the item of assembly costs.

The great flexibility in the properties which finished Bakelite may have is largely responsible for its extended use. Bakelite can be made to combine many different groups of essential or desirable properties. It is also made as a liquid or varnish in which form it is largely used for impregnating armature and other coils. In a somewhat modified form it is also used as a lacquer and protective enamel which can be applied by dipping, brushing or spraying. It differs essentially from other insulating compounds used for impregnating armature coils. When subjected to heat, Bakelite hardens, whereas most other compounds soften. After hardening, Bakelite has no melting point, but at temperatures in excess of 575 deg. F. it gradually carbonizes and disintegrates. Bakelite impregnating material bonds wires into a solid mass, preventing abrasive friction. It facilitates the dissipation of heat from the interior of the coils so much more rapidly than ordinary insulating compound that there is little danger from burnouts.

Bakelite micarta and dilecta are trade names for a material built up of laminations of paper coated and impregnated with Bakelite. These materials have qualifications which render them superior to fiber.

While there is as yet no accepted standard test piece or test method for measuring dielectric strength, the product as applied to automobile use will have a resistance of 250 to 300 volts per mil. Other properties are specific gravity, 1.33, temperature resistance 250 to 300 deg. F., and tensile strength of 4000 to 4500 lb. per sq. in.

Factory Miscellany

Hyatt Top to Establish Plant—The Hyatt Auto Top Co., Trenton, N. J., will establish a plant on Wood Street, Trenton.

Columbia Truck Will Build—The Columbia Motor Truck & Trailer Co., Pontiac, Mich., will build a plant 60 by 200 ft. at Pontiac.

Brockway Truck to Build—The Brockway Motor Truck Co., Corning, N. Y., is taking bids for its factory, which will be 40 by 186 ft., two stories.

Perfection Oiler to Build—The Perfection Automobile Oiler Co., Seattle, Wash., will build a plant to manufacture its devices. This concern was recently incorporated with $100,000 capital stock.

Beaver Motor Adds—The Beaver Motor Car Co., Gresham, Ore., will construct an addition to its factory, 32 by 70 ft., to be used as a foundry. It will be equipped with the latest type of machinery.

Pierce-Arrow to Build Laboratory—The Pierce-Arrow Motor Car Co., Buffalo, N. Y., has let contract for the erection of a laboratory and experimental building, 50 by 90 ft., two stories, at its plant at Elmwood Avenue and New York Central Railroad Line.

Akron Double Tread Adds—The Akron Double Tread & Tire Co., Jefferson Avenue, Akron, Ohio, contemplates constructing a two-story reinforced concrete, brick and steel factory addition to cost $30,000. No details decided.

Schacht Truck Moves Plant—The G. A. Schacht Motor Truck Co., Cincinnati, is moving its plant from Spring Grove Avenue to the manufacturing building at Gest and Evans streets. It will increase its manufacturing facilities.

Mutual Wheel to Add—The Mutual Wheel Co., Third Avenue and Sixth Street, Moline, Ill., has taken out a permit to build a four-story building to cost $10,000. It will be of brick, and will be used for the manufacture of automobile wheels. The company has been making wagon and buggy wheels.

Milwaukee Engine Co. Adds—The Milwaukee Auto Engine & Supply Co., 708 Winnebago Street, Milwaukee, Wis., has awarded contracts for the erection of its new factory at Twenty-eighth Street and Meinecka Avenue. The building will be of brick and steel construction, fireproof, one and two stories high, 60 by 120 ft. in size and contains an electric elevator.

Frome Co. Adds—The R. L. Frome Mfg. Co., box manufacturer, Howard's Grove, Wis., plans to manufacture motor trucks on a small scale. A 36 by 38-ft. addition is being made to the plant, to accommodate experimental work. The company plans to be ready to start production in March.

St. Albans Buildings Leased—The old buildings of the St. Albans Foundry & Implement Co., St. Albans, Vt., have been leased to the Foundry, Motor Car & Manufacturing Co., representing several St. Albans interests, and will be used for the carrying on of a general automobile business as well as manufacturing and general machine work.

To Make Tops—The Consolidated Auto Top Co., Detroit, Mich., has been organized and incorporated, its capital stock being $10,000, to make automobile tops. The incorporators of the new concern are C. P. Sieder, formerly president of the Sieder Mfg. Co.; L. N. Gay, formerly manager of the American Top Co., and H. R. Bidwell, formerly foreman of the American Top Co.

The Automobile Calendar

Dec. 31-Jan. 8	New York City, Sixteenth Annual National Automobile Show; Grand Central Palace; N.A.C.C.
1916	
Jan. 5-6	New York City, S. A. E. Winter Session, Standards Committee Meeting.
Jan. 7, 8, 10, 11	New York City Convention National Assn. of Automobile Accessory Jobbers.
Jan. 7-13	Milwaukee, Wis., Show, Auditorium.
Jan. 8-15	Cleveland, Ohio, Show, Wigmore Coliseum, Cleveland Automobile Show Co.
Jan. 8-15	Philadelphia, Pa., Show, Philadelphia Auto Trade Assn.
Jan. 13-18	Columbus, Ohio, Show, Memorial Hall, Columbus Automobile Club and Columbus Auto Trades Assn.
Jan. 14-22	Dayton, O., Show, Delco Bldg., Dayton Automobile Dealers' Assn., and Dayton Accessory Dealers' Assn.
Jan. 10-15	Fort Wayne, Ind., Show, Auto Trade Assn.
Jan. 10-15	New Bedford, Mass., Show, State Armory.
Jan. 15-22	Detroit, Mich., Show, Detroit Automobile Dealers' Assn.
Jan. 17-22	Rochester, N.Y., Show, Exposition Park, C. A. Simmons, Mgr.
Jan. 17-22	Wilmington, Del., Show, Wilmington Automobile Show Assn.
Jan. 18-21	Fargo, N. D., Show, North Dakota and Minnesota Automobile Dealers' Assn.
Jan. 18-22	Baltimore, Md., Show, Fifth Regiment Armory.
Jan. 18-22	Lancaster, Pa., Show, Conestoga Park Pavilion.
Jan. 22-29	Montreal, Que., Show, Almy's Bldg., Automobile Trade Assn., Ltd.
Jan. 22-29	Chicago, Ill., Show, National Automobile Chamber of Commerce; Coliseum and First Regiment Armory.
Jan. 24-30	Portland, Ore., Show, Armory, Portland Automobile Dealers' Trade Assn.
Jan. 24-29	Buffalo, N. Y., Show, Buffalo Automobile Dealers' Assn., Broadway Auditorium.
Jan. 29-Feb. 5	Columbus, Ohio, Show, Memorial Hall, Columbus Automobile Show Co.
Jan. 29-Feb. 5	Minneapolis, Minn., Show, National Guard Armory, Minneapolis Trade Assn.
Feb. 1-3	Frederick, Md., Show, Armory.
Feb. 2-5	Poughkeepsie, N. Y., Show, State Armory.
Feb. 7-12	Kansas City, Mo., Show, J. I. Case T. M. Bldg., Kansas City Motor Dealers' Assn.
Feb. 8-11	Grand Forks, N. D., Show, Auditorium.
Feb. 9-12	Peoria, Ill., Show, Coliseum, Peoria Automobile and Accessory Assn.
Feb. 12-19	Hartford, Conn., Show, First Regiment Armory, Hartford Automobile Dealers' Assn.
Feb. 14-19	Des Moines, Ia., Show, Des Moines Auto. Dealers' Assn.
Feb. 14-19	Winnipeg, Man., Show, Ford Plant, Winnipeg Motor Trades Assn.
Feb. 19	Newark, N. J., Show.
Feb. 20-27	Grand Rapids, Mich., Show, Klingman Furniture Exhibition Bldg., Automobile Business Assn.
Feb. 21-26	Louisville, Ky., Show, First Regiment Armory.
Feb. 21-26	Omaha, Neb., Show, Omaha Automobile Show Assn.
Feb. 21-26	Portland, Me., Show, Exposition Bldg.
Feb. 21-26	Syracuse, N. Y., Show, Syracuse Automobile Dealers.
Feb. 28-Mar. 3	Pittsburgh, Pa., Convention of American Road Builders' Assn., Mechanical Hall.
Feb. 29-Mar. 4	Ft. Dodge, Ia., Show, Terminal Bldg., Ft. Dodge Automobile Dealers' Assn.
March 4-11	Boston, Mass., Car and Truck Show, Mechanics Bldg.
Mar. 8-11	Mason City, Ia., Show, Armory.
Mar. 21-25	Deadwood, S. D., Show, Auditorium, Deadwood Business Club.
Mar. 28-Apr. 3	Manchester, N. H., Show, Under Auspices Couture Bros, Academy.
May 13	New York City, Vanderbilt Cup, Sheepshead Bay Speedway Race.
May 20	Chicago, Ill., Amateur Drivers' Race, Chicago Motor Speedway.
May 30	Indianapolis Track Race.
June 17	Chicago Track Race.
June 28	Des Moines, Ia., Track Race.
July 4	Minneapolis Track Race.
July 4	Sioux City Track Race.
July 15	Omaha, Neb., Track Race.
Aug. 5	Tacoma Track Race.
Aug. 18-19	Elgin Road Race.
Sept. 4	Des Moines Track Meet.
Sept. 15	Indianapolis Track Race.
Sept. 16	Providence Track Race.
Sept. 30	New York City Sheepshead Bay Race.
Oct. 7	Omaha Track Race.
Oct. 14	Chicago Track Race.

The Week in the Industry

Tracy Promoted—R. B. Tracy, formerly central manager of the Michelin Tire Co., Milltown, N. J., is now factory representative.

Mead Heads Vermont Firm—B. E. Mead has been appointed manager of the Vermont Auto Sales Co., Brattleboro, Vt., Chalmers agent. He was previously with Manley Bros., Vermont agents for the Hudson.

Middleton Succeeds DeWitt—R. T. Middleton has succeeded Frank DeWitt as Michigan representative and manager of the Steel Products Co. branch office in Cleveland, Ohio. Mr. Middleton has been the company's Central Western States' representative.

Neill G. M. Truck Mgr.—H. A. Neill has been appointed manager of the Kansas City, Mo., branch of the General Motors Truck Co., to succeed Estel Scott, who recently resigned as the result of ill health. Mr. Neill was district representative of the company in Atlanta.

Suess Assumes Duties—J. B. Suess, who succeeded Don Johnson as manager of the San Francisco branch of the Stewart Warner Corp., has assumed his duties. Mr. Suess formerly managed the company's branch in Kansas City.

Vedder Makes Change—E. G. Vedder has been made salesmanager for the Gray Motor Co., Minneapolis, Minn., Studebaker dealer. R. A. Briggs has been sent over to the St. Paul branch, which has been established in a new building at Franklin and Ninth Streets, to take Mr. Vedder's place as manager there.

Reed Succeeds Murray—M. E. Murray, who was recently appointed assistant general manager of the Republic Rubber Co. of Youngstown, Ohio, has been succeeded as president of the Republic Rubber Co. of California, the Pacific Coast branch of the Youngstown factory, by Irwin Reed. The latter was formerly manager of the Los Angeles branch.

New McGraw Tire Mgrs.—The McGraw Tire & Rubber Co., East Palestine, Ohio, has established truck tire branches in Buffalo, Detroit and Kansas City. G. J. Marshall will manage the Buffalo department; the Detroit branch is in charge of G. W. Tiffany, with headquarters in the Dime Savings Bank Bldg., and the service station at 26 Franklin Street; and the Kansas City department is under management of C. H. Connelly, who also has charge of the pneumatic sales in that territory.

Motor Men in New Roles

McClellan Tire Agent—J. R. McClellan has been named manufacturer and sales agent in Philadelphia for the McClellan tire, with headquarters at 817 North Broad Street.

Brebner Maxwell's New Castle Superintendent—Frankl Brebner has been appointed general superintendent of the Maxwell Motor Co. plant in New Castle, Ind. He succeeds W. B. Jameson.

Mayl Firestone Memphis Mgr.—J. E. Mayl, formerly sales manager of the St. Louis branch of the Firestone Tire Co., has been appointed branch manager for the same company at Memphis, Tenn.

Bartling Makes Change—E. F. Bartling, formerly general manager of the Auto Tire Sales Co., St. Louis, has become connected with the Nat L. McGuire Oil & Supply Co., 2924 Locust Street, St. Louis.

U. S. Tire Changes—Tom Wilkinson has been appointed manager of the San Francisco branch of the United States Tire Co., New York City, succeeding W. B. Rigdon, who goes to the Boston branch.

Damon Heads Boston Hollier—H. A. Damon, formerly sales manager of the New England agency for Michigan cars, with headquarters at Boston, Mass., has been placed in charge of the sales of the Hollier Motor Car Co.

Davis Heads Portland McGraw Tire—C. E. Davis of Portland, Ore., has been appointed manager of the Portland, Ore., branch of the McGraw Tire & Rubber Co., which has established quarters at 344-348 Burnside Street.

Brandt Makes Cleveland Connection—J. A. Brandt, formerly with the Quaker Tire & Rubber Co., has been appointed manager of the Euclid Avenue branch of the Collister & Sayle Co., automobile accessories and supplies, at Cleveland, Ohio.

Topken in Tacoma—F. W. Topken, A.S.M.E., for 11 years chief designing engineer of the Chicago Pneumatic Tool Co., is now in complete charge of the mechanical and garage departments of the Hunter-Smith Sales Co., Tacoma, Wash.

Schaeffer Enters Motor Field—L. P. Schaeffer of Seattle, Wash., and for many years a well-known figure in banking circles, has joined the automobile merchandisers in that city and has become vice-president and manager of the William T. Patten Motor Car Co., distributer of Hupmobiles in Seattle and King County, Washington.

Raymond Heads Columbus Concern—The Brasher Motor Car Co., Gay and Fourth Streets, Columbus, Ohio, has made H. G. Raymond manager of the concern. H. L. Taylor will continue in the same capacity as assistant to the manager.

Riley Resigns—N. S. Riley, manager of the Studebaker automobile branch at Kansas City, Mo., has tendered his resignation. Mr. Riley was formerly connected with the vehicle department.

Ford Joins Stackpole Carbon—D. E. Ford has been made sales manager for the new Twin City branch of the Stackpole Carbon Co., with temporary quarters at 133 Hennepin Avenue. The Twin Cities have been put on a free delivery basis and a battery factory is to be built in Minneapolis.

Roberts Goes to St. Louis—H. J. Roberts, formerly with the Hudson and Chalmers companies in Detroit has been appointed sales manager of the George C. Brinkman Motor Car Co. of St. Louis, Maxwell distributers in eastern Missouri and southern Illinois.

Dr. Treat Joins G. M.—Dr. D. L. Treat, who was president of the National Bank of Commerce of Adrian, Mich., resigned to become head of the new welfare department of the General Motors Co. In this new institution Dr. Treat will not only supervise the hospital and medical work, but under his direction will be the educational work, the promotion of moral and sanitary work, the health department and many other works and departments, all having some relation to general welfare.

Firestone Appoints District Managers—The Firestone Tire & Rubber Co., Akron, Ohio, announces the appointment of three district managers, who will have headquarters at the home office and at the same time will work closely with the sales organization in the field.

D. C. Swander, formerly branch manager at New York City, will have charge of the Eastern district. He will be succeeded in New York by C. D. Studebaker, who becomes branch manager. E. W. BeSaw, formerly Des Moines branch manager, will look after the Western branches. G. A. Spohr, former salesman, succeeds Mr. BeSaw as Des Moines manager. N. B. Burwell of the home office sales department will take care of the South.

Trade News from the Southwest—The El Paso Rubber Co., El Paso, Tex., has moved into new quarters at 205 West San Antonio Street. A full line of Quaker, Goodrich, Diamond and United States tires is carried.

Mansfield & Condron are now handling the Simplex trailer at Tucson, Ariz.

R. W. Koerner, factory representative of the Ajax-Grieb Rubber Co., will shortly arrange for the opening of a branch in Phoenix, Ariz. Ajax tires have been handled there for the last year by Peters & Pemberton.

W. R. Edison recently purchased the Mission garage, El Paso, Tex., and has decided to do a straight garage business hereafter. In line with this policy he has relinquished the agencies for Chevrolet and Cole cars and Ajax tires. The Chevrolet is to be handled in El Paso territory by the Myers Motor Co., with Guy Watts as sales manager.

A. E. Culbertson, formerly of Phoenix, is now sales manager for the D. L. Meloy Motor Co. at Globe and Miami, Ariz. He is devoting most of his time to the sale of Studebakers. E. L. Meloy, Jr., is handling Chevrolets for the firm.

The Goodyear Rubber Co. has opened a branch at Phoenix, Ariz. Temporary quarters have been secured at 133 North Central Avenue. The new building was ready for occupancy Jan. 1. H. T. Roseland, formerly of Syracuse, N. Y., is manager.

Dodge Bros. Add Shop—Dodge Bros., Detroit, Mich., are erecting a press and die shop, four stories.

Kansas City Items—The Hudson-Brace Motor Co., 1717 McGee Street, Kansas City, Mo., has doubled its space by constructing a new one-story building extending back to Oak Street. The company is the distributor of the Hudson car in the Kansas City territory.

Bruening Bros. Auto Co., 1712 Grand Avenue, will move into the quarters now occupied by the Studebaker Corp. at 162 Grand Avenue. The Studebaker company will move into a new five-story building at Twenty-first Street and Grand Avenue. Bruening Bros are distributors for the Apperson and KisselKar.

Seattle Trade Happenings—The Federal Rubber Mfg. Co., Milwaukee, Wis., has opened a direct factory branch in Seattle, Wash., to supply the trade in this city and the Northwest territory. A spacious location at 1921 Fifth Avenue has been obtained. F. B. Bloom, who is well known in the tire business on the Pacific Coast, is in charge of the branch.

Construction of a two-story building at the corner of East Pine Street and Bellevue Avenue, to be occupied by motor car, repair shops and body painters, has been begun, and the structure will be ready for occupancy by Feb. 1. It will be the new home of G. L. Trotter, agent for Reo and Stewart trucks and Stearns-Knight cars; R. S. Taylor, machine shops, and Pike & Lind, automobile body painters. The building is completely electrified, even to the heating system.

New Simms Stations—The following concerns have been appointed service stations for Simms magnetos and Simms-Huff electric starting and lighting systems. They are prepared to give factory service and prices, as well as guarantee work: Panhandle Motor Co., 604 Polk Street, Amarillo, Tex.; E. H. Odom Bros. Co., 43 Ivy Street, Atlanta, Ga.; Dallas Magneto & Starter Co., 529 S. Ervay Street, Dallas, Tex.; Edwards-Sutton Specialty Co., Armory Bldg., Sixth and Canal Streets, Dayton, Ohio; Denver Auto Goods Co., 1600 Broadway, Denver, Colo.; Kelley Hardware Co., 118 W. Superior Street, Duluth, Minn.; Indiana Electrical Service Co., 419 N. Capitol Avenue, Indianapolis, Ind.; Reinhard Bros. Co., Minneapolis, Minn.; Essex Storage Battery & Supply Co., 272 Halsey Street, Newark, N. J., and Ignition Specialties Co., 798 Seventh Avenue, New York, N. Y.

New Willard Stations—The Willard Storage Battery Co., Cleveland, Ohio, has brought the number from 500 to nearly 600 within a few months. There are now 579 Willard stations, as a result of the adding of the following: I. Lesses, Kingston, Ont.; W. J. Patton, Portsmouth, Ohio; Wolverton Electric Co., Lawton, Okla.; Chillicothe Battery & Supply Co., Chillicothe, Mo.; Miller & Reed, Clay Center, Kans.; Dodge City Vulcanizing & Storage Battery Station, Dodge City, Kans.; Ray Ryan Electric Co., Pittsburgh, Kans.; Albert Lea Storage Battery Co., Albert Lea, Minn.; F. J. Barnes, Blue Earth, Minn.; Nelson Auto Company, Benson, Minn.; National Garage, Crookston, Minn.; W. H. & Webster Jones Co., Brattleboro, Vt.; David City Battery Service Station, David City, Neb.; The Hanford Garage, Hanford, Cal.; Lounsbury & Shaffer, Merced, Cal.; Bogles Electrical Works, San Rafael, Cal., and the Electric Garage, Tulare, Cal.

Seattle Overland to Enlarge—Nine hundred thousand dollars in improvements is to be spent within the next few months by the J. W. Leavitt Co., Seattle, Wash., Pacific Coast distributor of the Willys-Overland Co., in enlarging and bettering the facilities of the firm's branches.

Ground has been purchased in San Francisco at the corner of Van Ness Avenue and Bush Street, upon which will be erected a building costing $400,000, which, it is declared, will be the finest automobile building in the world. The Los Angeles branch is to be improved to the extent of $250,000; Pasadena, $50,000; Oakland, $60,000; Sacramento, $100,000. These new structures, along with the recently completed buildings in Seattle and Portland, will give the Leavitt corporation a total of 436,500 ft. of floor space devoted to the sale, storage and mechanical service shops of Overland cars.

Late Illinois Items—A new garage and sales agency will shortly be opened in Havana, Ill. R. O. Curless of Peoria, is to be the proprietor. He has leased the vacant building of the J. B. Smith Manufacturing Co. on South Water Street, at the corner of Jefferson Street. C. P. Schmidt has been engaged to look after the mechanical and service department. The new firm is to be known as the Havana Auto Co. The Reo car will be handled at the outset and others may be taken on later.

The Auto Tire Boot Co., Chicago, has been incorporated with a capital stock of $2,500, to manufacture and deal in automobile supplies, parts and accessories. The promoters are Samuel Dulsky, Louis Dulsky, and Hanna Schooler.

The Mendota, Ill., Auto Co. has been incorporated with capital stock of $50,000 to deal in automobiles, motors and gasoline engines. The incorporators are John Goebel, August Goebel and V. C. Schaller.

A new service and assembling plant for the Pinkerton Motor Co., distributor of Ford cars, was opened in Pekin, Ill., on Jan. 1. L. J. Malone will be the manager. Ten machinists will be employed in assembling the cars after shipment from the factory.

The firm of McClure & Slingoff, for several years engaged in handling automobiles and supplies in Arrowsmith, Ill., has moved to 217 East Front Street, Bloomington, Ill., and will handle the Velie and Interstate cars.

Recent Baltimore Trade News—The Monumental Motor Car Co., agent for the Kissel, with temporary quarters at Howard and Franklin Streets, Baltimore, Md., has opened a service station at 504 St. Paul Street.

The Storage Battery Service Co., Inc., has opened for business at 1014 Morton Street, Baltimore, Md.

The Auto Supply Co., T. G. Young, president, 217 West Saratoga Street, Baltimore, Md., has taken the agency for Maryland for Wonder Mist, manufactured by the Wonder Mist Co., Boston, Mass.

Tabernacle Garage in York—A tabernacle converted into a garage is the latest plan of the J. W. Richley Automobile Co., 237 East Philadelphia Street, York. The company this week purchased the spacious tabernacle on the old reservoir lot, South Queen Street. The building will be used by the automobile concern for storage purposes and to display automobiles. Mr. Richley has the agency for the Ford, Buick and Hudson cars.

Patented by Hudson
December 28, 1915
Patent No. 1165861

Hudson Super-Six

Eights and Twelves Defeated by a Six

THE facts about the Super-Six seem almost like fiction.

Think of increasing motor efficiency 80 per cent at one jump without adding size or cylinders.

Think of a small, light Six—cylinders 3½ x 5—developing 76 horsepower.

Think of that Six, in official tests, breaking all stock-car records.

Think of a simple, light-weight Six out-matching Eights and Twelves.

And think of a $1375 car proving itself, beyond possible question, the best performing car of the day.

MEN WILL HAVE THAT 80%

This motor's capacity is 288 cubic inches. The best former motors in that size delivered about 42 horsepower. The Super-Six delivers 76 horsepower.

Any motor which shows about half that efficiency will have no attraction now.

This extra 80 per cent means more than added reserve power. It comes through ending vibration. All this super-efficiency comes through saving power which former motors wasted within themselves.

So it means vast economy. It means such smoothness as you never have known before. It means matchless flexibility. It means, as shown by official tests, record quick response.

Every quality men prize in a motor has been bettered vastly in this Super-Six.

EXCLUSIVELY HUDSON

Now, for the first time, a premier attraction is found in one car only.

The Super-Six is a Hudson invention controlled by Hudson patents. So no other car will have it. And any like performance is impossible without it.

Eights and Twelves of the finest types have been utterly defeated. Every reason for a double motor, with its extra weight, has vanished. Not a Six of the old type has any chance in comparison.

So this invention gives the palm to Hudson, over all cars in the field. One ride in the Super-Six will convince you of that.

$42,000,000 OUTPUT

We have doubled our factory because of this invention. And we shall build this season $42,000,000 worth of these Super-Sixes.

They come equipped with most luxurious bodies. All that we save by this doubled production has gone into extra elegance.

So the Super-Six will stand supreme both in motor and in looks. Any Hudson dealer stands ready to prove that to your fullest satisfaction.

7-Passenger Phaeton, $1375 at Detroit.

Five Other Body Styles.

Super-Six Catalog Is Ready.

HUDSON MOTOR CAR
COMPANY, DETROIT

World's Records Broken

All Records up to 100 Miles

Made at Sheepshead Bay under supervision of American Automobile Association, with a 7-passenger stock-car Super-Six. Breaking all stock-car records for any size, or any price, or any number of cylinders.

100 miles in 80 min., 21.4 sec., averaging *74.67 miles per hour*, with driver and passenger.

Previous best stock-car record was made with a multi-cylinder car carrying driver only.

75.69 miles in one hour with driver and passenger.

Two laps made at 76.75 miles per hour.

Standing start to 50 miles per hour in 16.2 sec. A new record in quick acceleration.

Digitized by Google

Experiment or

(Means uncertainty of success)

Experience

(Means certainty of success)

TWO letters are all the difference in the *LOOKS* of these two words, but "*experiment*" means *uncertainty* and "*experience*" means *certainty*, based on expert knowledge, when applied to speedometer construction.

Long ago we discarded the uncertain centrifugal principle of speedometer construction, as our experience, and that of 95% of all car makers, proved that the MAGNETIC PRINCIPLE is the only correct one for speedometers.

Experiments along *any other* lines have always proved unsatisfactory.

Every car owner wants the Stewart, which is the product of all that experience dictates to give lasting service with absolute accuracy under all conditions. FORD Owners must buy their speedometers from dealers now. They demand the Stewart. Why take chances at all?

Stewart Speedometer

MAGNETIC TYPE

for FORD Cars - $10

The AUTOMOBILE

Truck Industry Triumphant

Foreign and Domestic Demands Eclipse All Records—Better Trucks, Better Finance and Better Prospects Rule for 1916

By A. Ludlow Clayden

ABSORBED as we have been in the spectacle of prosperity presented by the passenger-car industry, we may, perhaps, have overlooked that of the sister industry caring for the demands of users of commercial vehicles. Yet never before has there been such a year of advancement in the truck field, never before have prospects for the future looked so bright throughout the world.

There is a tendency to look upon American truck-building prosperity as a thing fostered by war and sure to wane as peace once more resumes its sway over the civilized world. But, though fostered by war, without doubt there is no more reason for anticipating a slump with peace than there is reason to assume that the roses will wither directly the manure around the roots of the tree is absorbed. Growing slowly from year to year the commercial motor vehicle needed a stimulus to jump it from its adolescence to its manhood, and war has supplied that need. Once man's estate is reached and realized, however, one can never be a child again, and so with the motor truck industry—it can never again lose the place it now occupies, but will go on to work out its great destiny.

War has supplied three things: It has supplied money, money to buy trucks and so keep running the premier factories throughout the world on war supplies. It has supplied money that is being applied to the betterment of those premier companies—money which will see them in a better state at the end of their war orders than they were before the war orders began.

It has supplied advertising, the greatest advertising any industry ever had. To open an illustrated paper in America, France, England, Italy or Germany, without seeing a picture of motor trucks at work is almost an impossibility and has so been for nearly two years past.

Every civilized man now knows that the armies of the belligerents depend for everything, almost, upon their mechanical transport. That men, food and goods of warlike nature need the motor truck more than the horse; that animal transport is of infinitely less importance than automobile.

It has supplied a market, for war has stripped Europe of its horses and depleted the supply of animals throughout the globe. Every merchant who has to handle goods must for ten years and more to come pay a higher price for animals than ever in history. For years it will be actually hard to obtain horses for ordinary trade purposes throughout Europe. Hence the economies of motor transport, for goods will be obtainable at a capital outlay exceeding that necessary for horse equipment by a smaller amount than ever before.

Thus it may be said with conviction that if war has brought prosperity to the commercial motor vehicle industry, this prosperity will be one of the all too few *good* things that war will leave behind it when the events of the present have become but a nightmare memory.

We have seen throughout the world a year in which the domestic demand for trucks has eclipsed all previous records—a year in which the export demands have eclipsed all previous records also, *apart from war orders*. Between January, 1914, and January, 1917, the motor truck comes into its own.

In 1915 competition in the truck field has been less

United States

*Including Greater New York, Greater Boston, Greater Los Angeles and St. Paul with Minneapolis.

keen for two reasons. One is that the firms securing war orders have had so many less trucks to dispose of domestically. In round figures, 24,000 trucks have been exported, and that 24,000 represents just about 30 per cent of the total output. You cannot remove a third of an industry's product without easing competition in the disposal of the remaining two-thirds.

The other reason is that for the 74,000 trucks which were sold in America last year there were more than that number of buyers. The demand has exceeded the supply, and selling is easy under such a condition.

From these generalities there arise many interesting questions for speculation and analysis. For instance, it may be asked what effect has the absorption of certain makes of trucks for war purposes had upon the domestic trade of these manufacturers? Several of the leading makers of trucks in America have secured orders covering a very large share of their output. Is their trade eventually to gain or lose by this war business?

This is a question that each man must answer as he sees it, but it is easy to observe that those firms who are enjoying the war orders are mostly also enjoying a home demand for their trucks greater than ever before. It seems that each war supplying firm has had a row of buyers sitting on its doorstep waiting patiently for such odd trucks as they could snatch. Some of the concerns most deeply involved have, by increasing their capacity, been able to enlarge their domestic sales as well as taking on a few thousand foreign orders.

We have to-day in the truck field full manufacturers who make every part of their trucks, partial manufacturers who buy some parts and make others, and assemblers who make none of their parts. The latter lead, as in the passenger-car field.

Looking around we can see the unmistakable nuclei of great truck-assembling factories with an easily traceable future leading up to outputs of 10,000 or more chassis per year. We see factories making nothing but truck axles, nothing but truck motors, all building, all adding new equipment. This development is natural, was bound to take place, but had it not been for the war it would have been much longer in reaching its present stage, perhaps.

We have said that the removal or partial removal from the competitive home market of some of our big producers has helped the smaller men, and it is reasonable to ask what may then happen when the former have completed their war contracts. One can but speculate, but there is good reason to assume that the other firms have made such good use of the opportunity offered them that their position will be unassailable. The present American demand is capable of absorbing many more trucks than are now available. The world is able to take five times the number, so there should be no room for doubt as to the prosperity of the next few years not merely continuing but growing even greater.

Export Field is Wide

What markets there are in the world as yet hardly touched. All Europe is waiting for the inexpensive American commercial vehicle as well as for her own more costly product. There is room, after the war, for all the outputs of all the European factories and half those of the American plants as well. There is the British Empire, starved for supplies of motor vehicles of all kinds. There is Russia in Asia, where a tremendous wave of civilizing development is looked for after the war. By war a good half of the

Few Local Manufacturers

Local, confined to a city or county	2 2/3

Most Makers Build Bodies

Below, in percentages, is given the different policies in regard to factory-built bodies:

Body policy	Percentage
Standard bodies supplied	76
Stripped chassis only	13 1/4
Seldom supply bodies	8 3/8
All chassis sold with bodies	2 3/8

Many Concerns Extend Credit

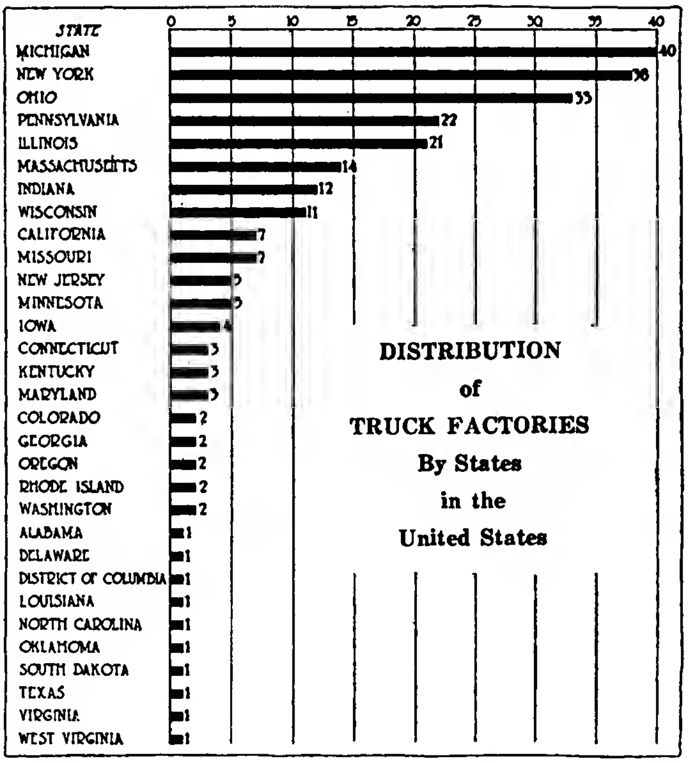
Credit policies of different manufacturers are given as to per cent in the table below:

Credit policy	Percentage
Have a credit scheme	46
Refuse to grant credit	40 1/2
Leave it to banks and credit brokers	5 3/8
Rarely grant credit	4
Leave matter to dealers	2 3/4
Extend credit locally only	1 3/8

world's road-transport vehicles, animal and mechanical, have been used up—destroyed forever. That the animal part will ever be replaced fully is more than doubtful, so the mechanical will be needed more than ever. No longer will it require educational work lasting over months to sell a truck, for there are hundreds of thousands of buyers waiting check book in hand for the chance to take delivery.

So much for the general situation as regards sales of the present and of the future. Internally, apart from the overseas market, there are changes to be observed which have an effect upon the whole situation.

For instance, the use of the trailer is growing immensely, and it is enlarging the scope of a truck. It is allowing a man with much to haul, in suitable country, to haul it more cheaply; it is making the motor truck still more economical in certain classes of application. The truck makers have been slow to approve the trailer, to-day none of them are actively opposed to it, most of them are ready to approve it within reason, and the balance approve it with certain restrictions as to loading and general usage. The present position is that the trailer will be used whatever the truck maker may think about it, so that the trailer may be regarded as having been forced upon the truck industry, the latter not being unwilling but merely a little coy regarding its new partner.



That the great commercial development should have gone hand in hand with engineering progress is natural; it is almost a law that one sort of progress should be accompanied by another, and thus we see the truck of 1916 a distinctly better machine as well as a distinctly cheaper one, on the average.

Methods of commercial handling of the business have changed a little also. There is a distinct increase in credit selling where the makers are absolutely satisfied that the buyer will find the use of the truck a real advantage. To take greater care in selecting credit customers and to be more ready to give credit to those who deserve it is the spirit of the hour. That the truck industry is being regarded rather more hopefully and confidently by the banking interests is also a fact, and doubtless this is partly owing to the creditable showing of the industry during the year.

There have been a number of reorganizations tending toward economy, there have been many new firms come into the business, but we have seen extremely few collapses, few instances of frenzied methods of business. It is as though every man in the truck trade was planning to make it his life's work; it is an industry lately almost untouched by that variety of speculator which the solid financial interests of the country distrust.

We have lately had occasion to remark that never did the immediate future of the passenger-car trade appear so fortunate. That we may truthfully say the same of its sister industry is much more than a happy coincidence. The purpose, the value—in a word the *efficiency* of the automobile was put to the supreme test in the fall of 1914.

The first six months of war proved that neither the truck trade nor the car trade could be injured by civilization's greatest catastrophe; proved that the automobile industry, in the widest sense of the word, is now one of the world's greatest necessities.

Most Trucks Are Assembled

Below are tabulated percentages of makers of motor trucks according to three methods:

Method of manufacture	Percentage
Assembled from standard parts	65 2/3
Partially assembled	23 1/3
Manufactured by maker	11

Trailers Are Generally Approved

The following symposium represents current opinion as to trailers among truck companies:

Trailer policy	Percentage
Approved	35 1/2
Not indorsed	18 3/4
Provision made for attachment	15 1/4
Indorsed under restrictions	13 1/3
Noncommittal	10 2/3
Optional with purchaser	5 1/4
Indorsed for country work only	1 1/4

Starter Question Unsettled

In the table below sentiment among builders is tabulated as to electric systems:

Electric starter policy	Percentage
Supplied on buyer's option	31 3/4
Not indorsed	22 2/3
Approved	21
Refuse to provide	7 1/3
Installed as stock equipment	6 1/3
Electric lighting only supplied	4 1/2
Noncommittal	3 2/3
Will be stock equipment later	1 3/4
Used on light capacities only	1

Truck Design Shows Many Changes

Worm Drive Gains Greatly—Average Capacity Enlarged—General Simplicity Improved

By J. Edward Schipper

TWO thoughts, either of which may be dominant according to the viewpoint taken, are suggested by a study of the past year in the motor truck industry. First, from the economical standpoint, trucks are better adapted to the particular task for which they are used than ever before. Secondly, from an engineering standpoint the mechanics and design of the vehicle have progressed far beyond the usual normal advance for a year. Behind these two conditions there are broad underlying reasons which at first sight would seem only indirectly connected with industrial and mechanical progress, but which on close examination prove to be the immediate cause of development.

Worm Drive Gains 100 per Cent

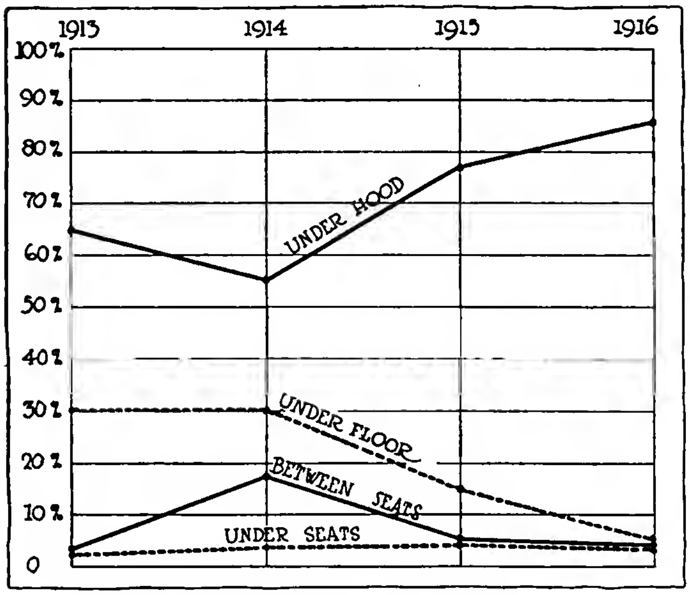
For instance, it seems far-fetched to suggest that Austria's ultimatum to Servia has anything to do with the fact that worm drive has increased over 100 per cent during one year on American motor trucks. And yet, the great war, which that ultimatum, like a torch, kindled throughout Europe, has had more to do with the phenomenal development of the motor truck industry in the United States than can possibly be conceived, except by careful analysis. The percentage of the $65,000,000 received from foreign countries for American trucks that found its way into the engineering departments of the manufacturers has done wonders in the improvement in design. The vast demand had enabled manufacturers to clean their stocks and start afresh on what was realized to be the best practice but which required great sums of money to put in operation. Better graduated capacities, better power plants, better power transmission systems and more efficient control layouts can be directly laid at the door of the greatest year ever known for export business.

One of the first things which manufacturers have done since the opportunity has been offered to supply what previous experience has shown to be essential for success is carefully to scrutinize the capacity problem. There have been some remarkable tendencies in this direction during the past year. The high spot is the development of the 2-ton truck. The overloaded 1-ton and 1½-ton vehicle is passing away, and in its place consumers who formerly through false economy believed that they could carry an occasional high overload are coming to realize that this is a mistake. The average capacity of gasoline motor trucks for 1915 was 4500 lb. For 1916 the average carrying capacity is 4840 lb. This is an increase of 340 lb. per vehicle, or approximately 7½ per cent.

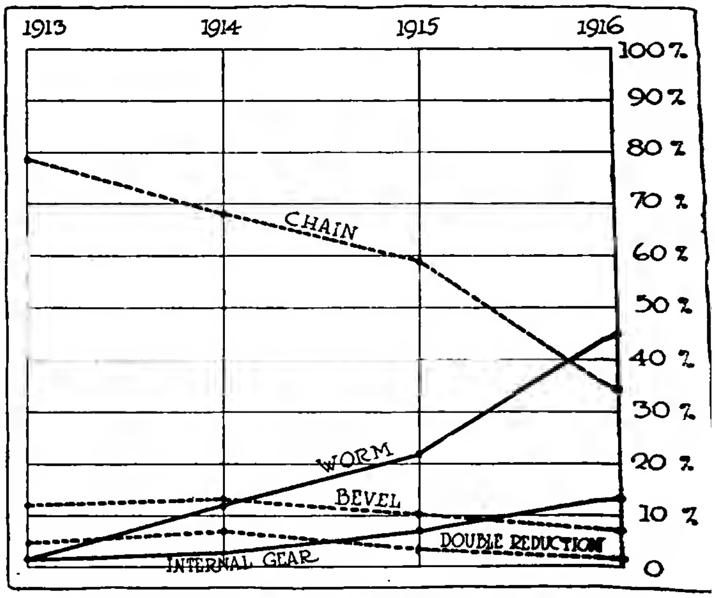
This change in the average capacity is more significant than that it merely represents an increase in the size of the body and the springs on the part of the maker. The manufacturer must supply what the consumer demands, and the fact that the capacity is higher shows that the consumer is buying larger trucks—not because the individual loads moved are any greater than they were a year ago, but because he is willing to pay relatively more for the truck and get what is economically correct.

Coming to the other great development of the year, shaft drive: this is another instance where the purchasers' wants are expressed in tangible form. Public opinion demands the worm drive, and the result is that chain drive has fallen from 58.7 per cent in 1915 to 33.4 per cent in 1916. Worm drive has increased from 21.5 per cent to 44.7. Internal-gear drive has increased from 7.3 to 12.2 per cent, while bevel drive has fallen from 10 to 7. Silence in truck operation has been demanded, and shaft drive is proving to be the answer. When a man buys a commercial vehicle he looks at the question from a business standpoint. In the first place he wants good service from the vehicle. This, in the light of present development, he has a right to expect, and he will receive it. He also wants ease of riding as a protection to the chassis and of the load, should the latter be fragile.

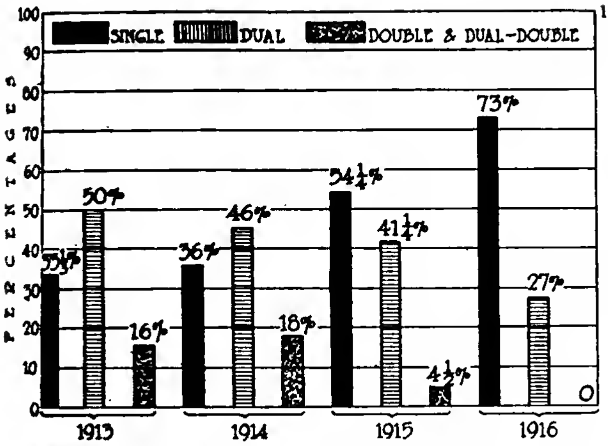
Noise, parts to clean, parts to replace and other inconve-



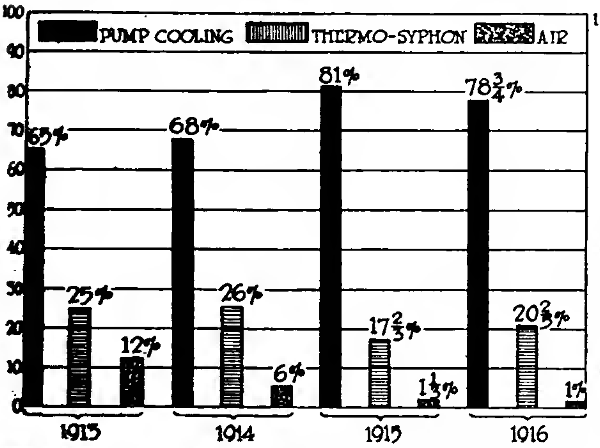
There is a marked trend toward the motor-under-hood construction



A feature of the year is the great gain of shaft drive



Progress in ignition shows a trend toward single systems



Pump cooling has fallen off slightly in favor of thermo-syphon, due to improved radiator construction

siences must be eliminated. When an intending purchaser is shown two trucks both doing their work equally well, one in silence and the other with noisy effort, he quickly turns to the quieter; this also for good business reasons.

As happens in every industry, as developments go on prices can be cut. More efficient tools, better design and big production have been the factors which have cut the prices in the manufacture of motor trucks. In 1915 the average price of a truck was $2,528. For 1916 the price is close to $2,413.

Better Trucks at Lower Prices

Trends in truck design follow somewhat along the lines of those in passenger-car work. The careful concentration on higher efficiency carries the two branches of motor car design along lines that are, in many instances, parallel. This is evidenced in the power plant to a great degree. In the first place the location of the motor under the hood instead of in less accessible locations is growing. Last year, 77 per cent of the chassis had the motors under the hood and in 1916 the percentage is 86. The gain in the under-hood location has been due to the falling off of the under-floor type. This has dropped from 13 per cent in 1915 to 4.2 per cent in 1916.

It would hardly be expected that the multi-cylinder motor would find favor in the truck field. This supposition is borne out and over 96 per cent of all gasoline commercial vehicles have four-cylinder motors. Sixes are represented by 1 per cent and twos by 2.4 per cent. This is the first year in a long time that there has been no representation of the three-cylinder two-cycle design, but it has now dropped to zero. The Duryea two-cylinder two-cycle delivery vehicle is the sole survivor of the two-stroke tribe.

Another way in which power plant design for the commercial vehicle parallels that of the passenger car is in the size. It is becoming smaller as time goes on and greater efficiency is obtained from smaller displacements. The average of all 1915 motors had a bore of 4.16 and a stroke of 5.25 in. The average 1916 truck motor is a 4 by 5.20 in. The smaller motor represents the trend toward compactness and this is further carried out by an increase in the percentage of block-cast cylinders from 54.2 in 1915 to 59 for 1916. To further increase the compactness of the average motor the T-head percentage is suffering in comparison with the gains made by the L-head. There are only 14 per cent which are T-heads now as compared to 17.5 per cent a year ago. The L-head is used on 82.3 per cent.

With the compact block casting with the neat L-head cylinder shape representing the average of truck design due to its preponderance in the percentage tables, it will not be surprising to note that the same trends toward compactness and simplicity will be found throughout the chassis. Take for illustration thermo-syphon cooling which shows a slight gain, and another point of great importance, the unit power plant which has jumped in one year from one-third of the installations to over one-half, the percentage readings for 1915 and 1916, respectively, being 33 and 52.2; the amidships location has gained 5.75 per cent over a year ago, this being due to the more extensive use of worm drive. This involves in some cases great shaft lengths which may very conveniently be reduced by placing the gearset mid-length of it, thus cutting down the free length. The unit jackshaft locations loss has been commensurate with the reduction in the number of chain-driven models.

Apropos of the question of driveshaft lengths, this is a problem introduced by shaft drive which is as yet unsolved. A shaft of too great length will whip and whirl in action, to the great detriment of its universals and the end bearings. One

Left steer's gain has been consistent. Right steer survives mainly for export sale

Italian Truck Makers Flourishing

Plants Are Able to Supply Other Countries as Well as Italian Army—Many New Designs—Fiats Predominate

By W. F. Bradley

Paris correspondent of THE AUTOMOBILE, *recently returned from examining the busy and prosperous automobile and motor truck industry in Italy. The following is the first of a series of articles on the subject and reviews the truck field*

Top—Scat motor for 4-ton army truck. Four-cylinder block 3.9 by 5.9-in. bore and stroke

Middle—Heavy duty Spa 3.7 by 7.8-in. bore and stroke for gun-carrying truck. Splitdorf magneto is fitted

Bottom—Lancia 2-ton truck, 3.9 by 5.5-in. bore and stroke motor. Note wood fan of aeroplane type

WITH a 700-mile front, it is obvious that the Italian army must make a very extensive use of automobile trucks. Prior to the war Fiat was the only firm producing trucks in big quantities and, although all other firms have devoted their attention to army vehicles, Fiats still predominate. This company's output is sufficient to supply the Italian army and leave a surplus for England, France, Belgium and Russia. The biggest type used in the Italian army is a 4-ton truck, which is of course a specially designed truck proposition; the smallest are 1-ton trucks on pneumatic tires, generally with twin tires on the rear wheels.

All Fiat trucks of 2-ton capacity and upward have inclosed chain drive; Spa, another big maker of trucks, also uses inclosed chains for final drive. Scat, the only other firm specializing in trucks, uses internal gear drive. These three firms are the only ones having paid really serious attention to truck design before the war, and building a truck which is not a touring car development. These firms, as well as all the others in Italy, are building shaft and bevel drive trucks of 1-, 1½- and 2-ton capacity, which are really nothing more than heavy touring cars. The greater proportion of these 1,- 1½- and 2-ton trucks are equipped with pneumatic tires, singles on the front wheels and twins on the rear.

No European army employs such a proportion of pneumatic-tired trucks as the Italian. The explanation is that the authorities wished to make use of trucks built in the country, and it was quicker for the manufacturers to fit a special rear axle and strengthen up the touring chassis generally, equipping it with twin pneumatics, than to get out special truck designs. It is certain that the arrangement is not the most economical, for all the Italian trucks are driven too fast and tire upkeep must be enormous.

Disk Wheels for Small Trucks

One of the distinctive features of Italian construction is the use of disk wheels for trucks up to 2-ton load. These wheels are detachable by unscrewing five or six nuts, and are very easy and cheap to construct, for they consist merely of a stamped steel disk riveted, and welded to a steel rim. The same type of wheel has been put on the market in France by Michelin, and is being used to a moderate extent for touring cars, but very little for trucks. In Italy, on the other hand, the disk wheel is used on all Fiat light trucks, this firm manufacturing them in its own shops, and on about 80 per cent of the entire Italian output of trucks up to 2-ton capacity. Cast steel wheels are employed almost exclusively for the heavier trucks, although the high price of the castings at the present time—about 17 cents per pound—has caused some attention to be paid to wood wheels. It is found, however, that there is very little saving in price.

It appears to be a general practice for the Italian makers to use close grained cast iron instead of aluminum for their heavy truck crankcases. This is done by both Fiat and Spa. This latter firm does not use paper gaskets at the base of the cylinders and between crankchamber and oil pan. The surfaces are so finely ground that they can be put together without any joint between them, and there is absolutely no oil leakage. This is done on trucks as well as on touring cars. The interiors of cast-iron crankchambers are painted as a protection against rust.

No Four-Wheel Drives

There appear to be no four-wheel drive tractors in Italy; at any rate none are being made by the Italian manufacturers. Heavy gasoline tractors, intended to operate away from made roads, and designed primarily for the haulage of heavy artillery, are being produced by several firms, notably Fiat, Isotta-Fraschini and Spa, and are claimed to give results equal to those obtained with the all-wheel drive type. The Fiat tractor is a chain-driven machine with 70-hp. motor under a hood, four-speed gearbox, jackshaft and incased chains driving large diameter cast-steel wheels with ribbed faces. Front wheels are fitted with Goodrich single-band tires.

The motor, which has a bore and stroke of 5.1 by 7.8 in., is L-type with cylinders cast in pairs, and is the only non-monobloc casting seen in Italy. Except for the pair casting it does not differ appreciably from Fiat truck motors. It is carried on a sub-frame and has half compression device which automatically retards the magneto, the advance being given with full compression and remaining fixed. On a cold morning it is not likely to be an easy matter to start a motor of these dimensions, and in consequence the starting handle is made of sufficient length for three men to get hold of it.

The position of the water pump is somewhat distinctive on the right-hand side of the motor, in a central position, with an inlet pipe to each group of cylinders. The magneto is immediately to the rear of the pump and driven off the same shaft. The gilled tube radiator is mounted in trunnions, and has a whistle in the filler gap, so as to give warning to the driver if steam begins to form.

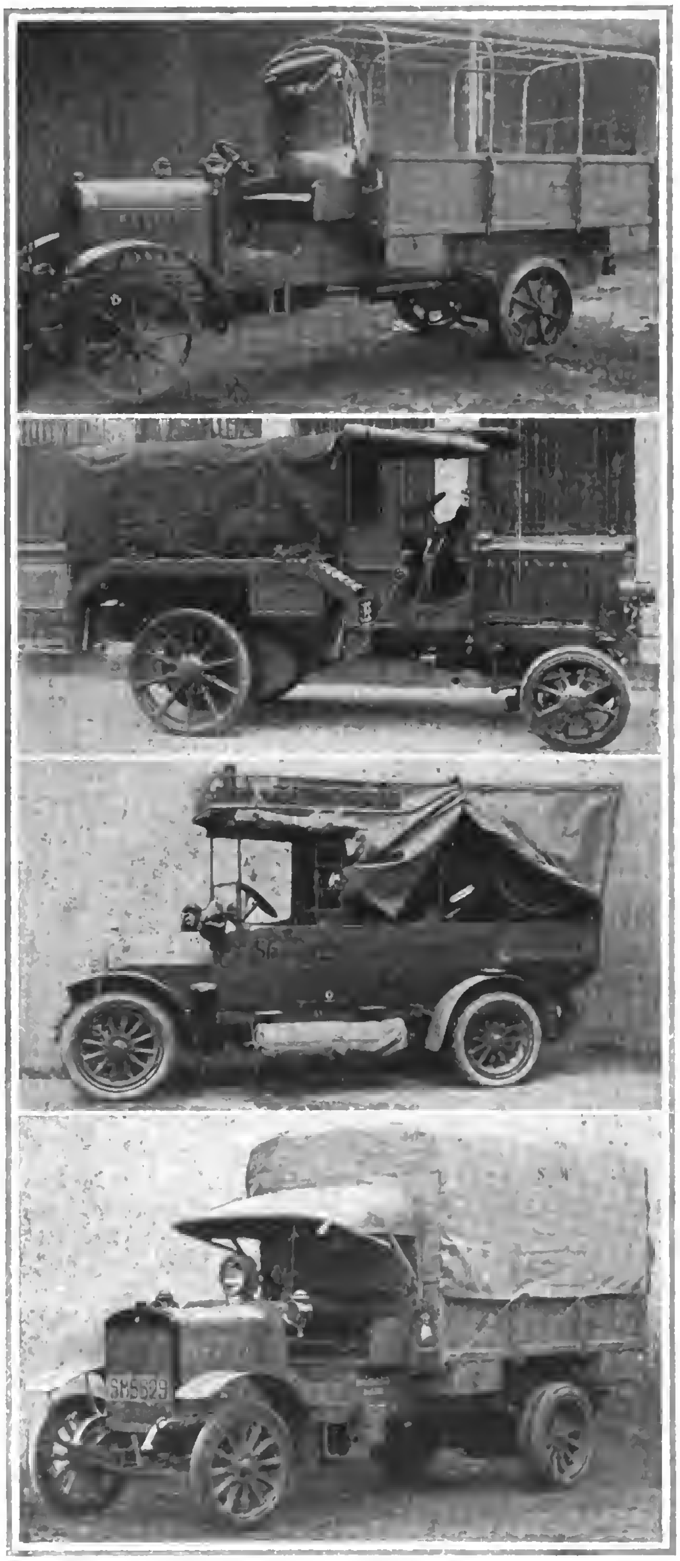
Cross-Members and Gussets for Strength

A very rigid chassis construction is obtained by closely placed cross-members and gussets. Between the motor and gearbox is a cast-iron housing attached direct to the frame members, containing the gearshifter mechanism, the brake control, and silent chain drive from main shaft to the winch shaft running alongside the left-hand frame member. It is by means of a dog-clutch, operated by the change speed lever, that the driving chain can be put into motion, all the gears then being locked in neutral.

Differential Lock on Fiat Tractor

The winch is mounted horizontally within the rear of the chassis and has about 50 yd. of ½-in. steel cable. There are guides on the chassis to allow the cable to be brought forward for hauling a vehicle in front without touching any of the mechanism. A differential lock is fitted; there are two water-cooled brakes on the jackshaft and on the rear wheels. The jackshaft brakes are operated together by pedal through a balance lever, but have a special mechanism by which they can be applied separately when going round sharp mountain turns. The chain cases are a stout casting, with sheet metal facing, having the radius rods combined with them and capable of taking the weight of the vehicle if the road wheels sink in soft ground.

All shackle pins are of big diameter and are bronze bushed. The rear spring shackles have a big oil reservoir cast with them, so that lubricant is automatically fed to the shackle pins. Spring clips are not often used on Italian trucks. Instead, the springs have a groove down their full length, to prevent them splaying sideways, and are assembled by being forced into a forged box, which is bolted to the spring seating on the axles. This does away with the center bolt and by rea-



A group of products of the Italian motor truck factories which are designed especially for use by the Italian army and comprising motor trucks, tractors for hauling heavy guns and special constructions for searchlight work. Note the camparatively short wheelbases of the vehicles and their simple but substantial construction, rendering them eminently suitable for field work of the roughest sort. Some of the chassis details are illustrated on pages 62 and 63

Top—Itala army type 3-ton truck

Upper Middle—Fiat military tractor used in the Alps for hauling heavy guns. Note flexible band for attaching to rear wheels. Goodrich band tires are used in front

Lower Middle—Fiat automobile searchlight for Italian army

Bottom—Diatto 3-ton truck for Italian army son of the bigger surface holds the leaves together more effectively than a single bolt. Scat has extended this idea to touring cars by putting the springs through the axle.

Can Be Caterpillar at Will

One of the patented features of the Fiat tractor is the caterpillar band attached to the driving wheels. When working under normal conditions, these bands are carried on a kind of platform forming a rear wheel fender. There are projecting studs from the inner face of the rear wheels, by means of which the bands are attached to the wheels. By means of these bands the tractor is able to operate across

Although similar in external appearance to the touring car type, the truck motor differs by reason of the external exhaust manifold, cast iron instead of aluminum for crankchamber, and the lower number of revolutions at which it is designed to run. Transmission is through four-speed gearbox to jackshaft, with double water-cooled brakes mounted on it, and final drive by inclosed side chains.

Many Special Army Trucks

A large number of special vehicles for military operations are being produced by the Italian factories. Fiat is build-

Lancia 2-ton chassis used by the British and Italian armies as an armored car

ing numbers of searchlights carried on a 2-ton chassis using pneumatic tires. The dynamo is mounted over the gearbox and driven by inclosed silent chain. The searchlight, which has a face diameter of 35 in. is mounted on a wire-wheel bogey. It is brought out of the car on rails and can operate several hundred yards from the generating car. A similar type of chassis is employed for wireless telegraphy. The English and French method of carrying gasoline is by means of 2-gal. cans. The Italians are making use of tank wagons, with pump and measuring instrument mounted on the rear end of the tank, this proving a much more economical and satisfactory manner of handling gasoline than the use of cans. Armored cars, generally fitted with two machine guns, are being produced in moderately large quantities for the Italian and other armies.

The armor plating is chrome-nickel steel 5 mm. thick capable of turning a rifle bullet at close range. Practically all these cars have twin pneumatic tires on the rear, with a housing around them brought as low as possible compatible with clearance. In some cases band tires are fitted on the front wheels, without any protection, the wheels being either cast steel or steel disk type. Other special machines are motor workshops, aeroplane tenders and trailers.

Before the war Italy did not possess a great number of automobile drivers, for practically her entire fleet of automobiles consisted of passenger cars. Thus, since the army has put into service several thousands of automobiles and trucks, it has been necessary to train drivers for them, with the result that more or less green men have been in charge of military material. The situation, however, has not been as difficult as in England and France, where there is in addition to the military fleet a very important commercial motor fleet for which drivers are found with difficulty.

When war broke out the Italian military authorities requisitioned practically all private cars. This part of the Italian military organization does not appear to have been managed in a very satisfactory manner. It is declared that the officers alone were judges of the value of a car, with the result that in some cases a fancy price would be paid, and in others the owner would get much less than the real value of his machine. Experience has shown that the best scheme is that in force in France, where the impressment officers have to work to a definite scale, based on the number of cylinders, horsepower, age, type of body, nature of tires, etc. Under this scheme the owner is at a disadvantage if his car has just come out of the factory or has just been completely overhauled, and the state loses if the car has been run as long as possible without extensive repairs.

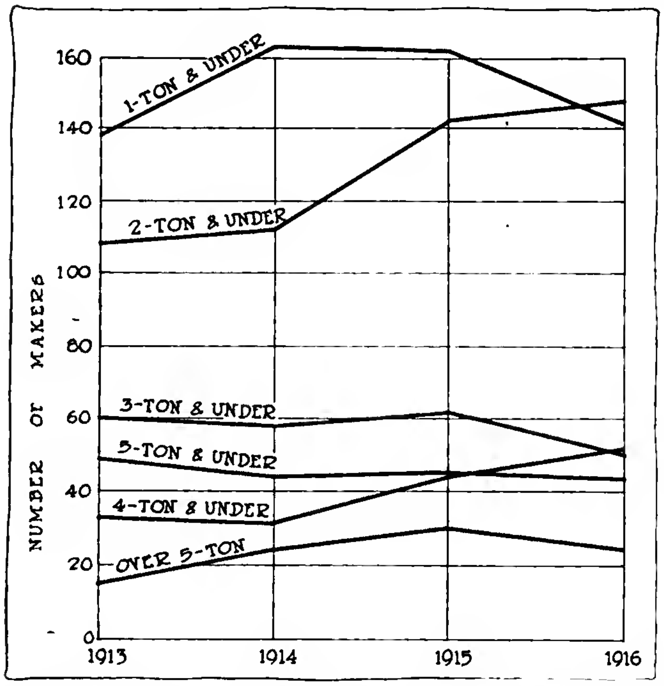
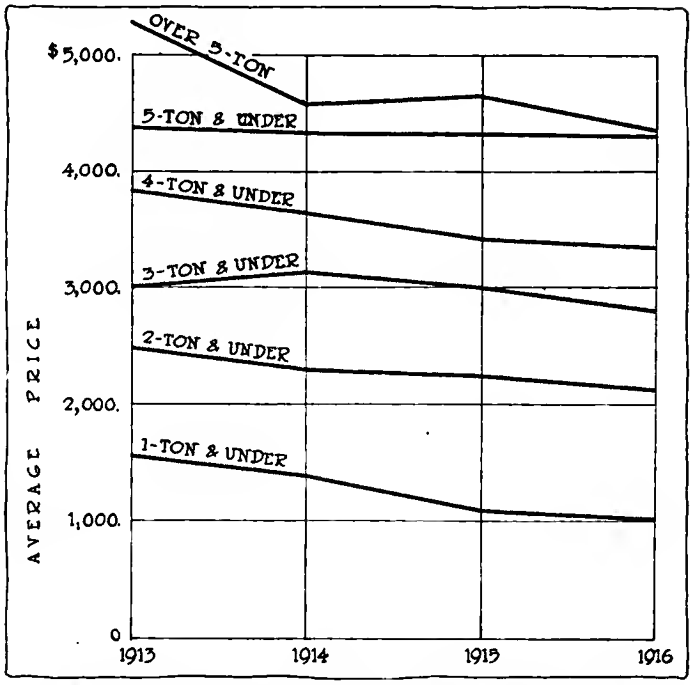
An Analysis of Tendencies in Load Capacities and Prices of Commercial Vehicles for Four Years



Above are illustrated the trends in load capacity, the number of makers of trucks of 1 ton and under jumping from 138 in 1913 to 163 in 1914 and holding to 162 the following year, the past year, however, showing a marked decrease to 141, a loss more than made up by the great increase in the number of makers of vehicles of 2 tons and under



Truck prices have been going down steadily during the past four years, the average 1-ton truck being $530.56 cheaper now than in 1913. Almost as marked a decline in price is shown in the 4-ton and under class which decreased its average price from $3,839.58 in 1913 to $3,413.64 for 1915 and $3,346.97 for 1916. There was a sharp drop in the price of the over 5-ton class during 1915

ENGINEERS COMPLETE WINTER SESSION

Nothing Settled by Ignition Talk

S.A.E. Discussion of Magneto versus Battery Inconclusive—Argument and Counter-Argument Leave Question Undecided

NEW YORK CITY, Jan. 6—The dominant feature of the winter professional session of the Society of Automobile Engineers, held at the Engineering Society Building here to-day, and which concluded the annual winter session of the society, was the discussion of battery vs. magneto ignition. That each has its field and its well-defined advantages was the conclusion reached by the majority of members, who were keenly interested in the discussion of this most pertinent factor of modern motor development. The session was well attended and demonstrated that the concentration of the professional work in one day is the wisest course.

The papers discussed were:

"Magneto vs. Battery Ignition," by Francis R. Hoyt, electrical engineer Simms Magneto Co., which stated the case for the magneto, claiming more power and general greater efficiency for the magneto system.

"Notes on Battery Ignition," by Alexander Churchward of the A. B. C. Starter Co., and "Battery vs. Magneto Ignition," by Frank Conrad, electrical engineer Westinghouse Electric & Mfg. Co., the two last named being opposed in their conclusions to the first paper.

Papers Taken Together

The papers were summarized in the last issue of THE AUTOMOBILE, and the discussion remained so general in character that there is no need to quote either paper in full detail.

Albion D. Libby, engineer of the Splitdorf Electrical Co., suggested that the discussion on all the ignition papers be taken together, and this was agreed to by K. W. Zimmerschied, chairman of the Standards Committee, who was presiding.

Battery Classification

Glenn S. Whitten failed to see the value of Mr. Churchward's classification of battery system, in which he mentions three different types, that having manual advance, that having automatic and that having semi-automatic advance. The proper classification he believes is the open and closed circuit.

Frank Conrad, Westinghouse electrical engineer, believes that in discussing ignition problems of to-day it is useless to bring up as an example a four-cylinder motor running at 1400 or 1500 r.p.m. The problem confronting ignition engineers now is eight- and twelve-cylinder motors running at 3000 r.p.m. Mr. Conrad declared it is not true that in the magneto the heat of the spark increases as the speed of the magneto increases. He said that this condition was merely due to the fact that there is an optical illusion in observing the discharge at the plug, because more sparks are created in a given amount of time. In justifying the claims for battery ignition, Mr. Conrad referred to the growing number using the battery ignition system.

Wm. G. Wall, National engineer, believes that all those who have used both types of ignition are likely to be prejudiced in favor of the magneto, and that he used to think magnetos were better because of the automatic advance feature, but has found that the advance is inappreciable and therefore, does not give any gain. "Of course," he went on, "the battery system has nothing to approach the automatic advance, although I think the magneto has advantages at high speed and I have had more horsepower output with magnetos. I had credited this to the follow-up current in the magneto. We see that the magneto is a self-contained instrument whereas the battery requires auxiliaries, and a generator is necessary. Furthermore, it is dependent upon the battery.

Question of Cost

"Both battery and magneto systems require power to drive them and the details are quite alike. The magneto has most of its parts near the driving system, while the battery has considerable wiring subject to troubles which may arise. There is no question that the battery system has great advantages and has been decreased greatly in cost. Therefore, many are coming to use it."

L. B. Brown of New York suggested that instead of the open-circuit and closed-circuit classification, the battery system be divided into cam-break and spring-break classes. In analyzing the advantages of the closed circuit, he stated that, if an ignition device were being designed for a single-cylinder motor, the period of contact of the primary would be made as short as possible. This same theory should apply to multi-cylinders.

R. H. Combs, Prest-O-Lite, took exception to Mr. Wall's remarks on the difficulties with battery systems due to the scattering of the units and said that as yet he has been unable to note any trouble due to this source.

Mr. Libby stated that while in his belief both battery and magneto ignition have their separate fields, it is incorrect to use a battery system on a car and then mark the switch as magneto. He also expressed himself as differing with Mr. Conrad's remark in his paper that there are space limitations with the magneto, thus cutting the voltage. He said that these remarks should not apply to the stationary-coil design on which there can be as many turns of secondary wire as are wanted.

Battery Exchange System

Regarding the battery situation, Mr. Libby said it is quite important to note the present tendency toward adjustments in battery exchange in the same way that adjustments are made on tires.

"This is a dangerous practice, as it results in the owner not giving attention to the battery, since he believes that for $5 he can secure a new battery. It often happens that owners will neglect the battery during the spring and summer and the result is that in the winter when the capacity of the battery is a limited percentage of the total rated capacity, the motor will not start." As an illustration to bring out the force of this statement, he stated that at 3 deg. above 0 deg. Fahr., the capacity of the battery is only 50 per cent of the rating.

Francis R. Hoyt took exception to Mr. Conrad's statement in saying that the spark heat does not increase with the speed on magneto ignition. He stated that this is entirely a matter of individual design and can be arranged to suit the engine. The reason for not furnishing more heat is simply that it is not necessary and not because it cannot be given. Another point which he brought out is that an error in timing of 1 deg. in the battery system is 2 deg. on the crankshaft, whereas generally magnetos are driven at crankshaft speed.

Herbert Chase, chief engineer of the Automobile Club of America, emphasized the point that in making ignition tests, the actual position of the spark in the cylinder is what should be observed and not merely the position of the spark lever on the steering wheel quadrant. He also said that Mr. Hoyt's statement that flame propagation depends upon the size of the spark has never been proved. He pointed out that once ignition is accomplished, no more effect occurs from a follow-up spark. Speaking from experience, as service manager at the Automobile Club of America, Mr. Chase said that the batteries on the car cause more trouble than any other detail.

Russell Huff, chief engineer of Dodge Bros. and president-elect of the S. A. E., said, "We are likely to lose sight of the part the carbureter plays in the successful ignition of the car. I would refer you to tests which have been made covering this identical subject. One speaker mentions the prolonged spark as a benefit. True, with poor carburetion a magneto will give more power, but when perfect mixtures are furnished it is not possible to get any more power from a magneto than from a battery. The magneto has not the range of advance of the battery system and I have found that the battery-ignited car will pull away from the magneto-ignited car on high speed. I have made tests on a motor which stood in a room 8 deg. below zero and the motor started on the third revolution of the crankshaft. I have seen this same motor fail to start in a warm atmosphere when suffering from a bad carbureter adjustment."

Examples of Large Advance

C. T. Kettering, vice-president of the Dayton Engineering Laboratories Co., cited a few examples of advance. He said that the Cadillac eight at 3000 r.p.m. and the Packard twelve at the same speed had 28 deg. advance while the Hudson six at 3000 has 27 deg. advance. Furthermore, he stated that it is not fair to attempt to analyze the whole problem from one type of ignition.

The Past and Future of the S. A. E.

President and President-Elect Review the Work Accomplished and the Tasks Ahead of the Society

NEW YORK CITY, Jan. 6—At the opening of the professional session of the S. A. E. in the Engineering Societies Building, President VanDervoort and President-Elect Russell Huff, each gave their views as to the past and future of the S. A. E.

President VanDervoort in opening the meeting made his parting address as a president of the S. A. E. He dwelt upon the accomplishments of the year and upon the outlook into the future. He stated that he had fully realized the responsibility of his position as president and that his only regret is that he was not able to accomplish more. He spoke of the importance of wisely selecting the officers and committees of the society in order that the work which has been planned will be successfully carried to a termination. Looking back over the year, Mr. VanDervoort said that the year had been one of constructive work by the society.

Following President VanDervoort, President-Elect Russell Huff told how he had taken part in the earlier development of the society and dwelt especially on the vast importance of the standardization work, saying that it had saved millions of dollars to the industry though as yet the work had but scratched the surface of what remained to be done.

Extracts from Presidentisl Address

After stating his appreciation of the position he held as president of the society Mr. VanDervoort continued:

"I have keenly appreciated the friendly and loyal support you have all given me and shall always look back upon the year of work and association with you as a most pleasant one. It has been a year of constructive work marked at every turn with that spirit of unselfishness, of cooperation and untiring effort on the part of all that has become characteristic of the entire industry of which the Society of Automobile Engineers constitutes so important an element. The story of the development of this industry reads like a fairy tale and to the engineer is due in large measure credit for the remarkable growth of the industry.

"It is to be regretted that our membership has, during the past year, fallen off somewhat. We believe, however, the standard of membership has improved. The past year included several of the very worst months of the recent business depression. Many good members found it necessary, for financial reasons, to drop out, and for the same reason much good material found it impossible to join. Again, we have systematically cleaned the membership lists of much dead material, leaving it at the present time in a most healthy condition. It has also been the policy of the council to scrutinize most carefully the qualifications of all applicants in the belief that we should first build up the quality of our membership and its work with the assurance that by so doing we will attract to the society the best membership material. I believe that although slightly weaker numerically, we have gained much in efficiency, 'By our efforts they shall know us.' Let us all look upon our membership in the Society of Automobile Engineers as an asset of no mean value and let us gain in our work that recognition which will bring the unqualified support of every engineer and manager associated with the automobile industry.

Standards Not Realized

"I fear that the managements of many of our great automobile and accessory companies are not well informed as to the work the Society of Automobile Engineers is doing. They are all interested in the work of the society, either directly or indirectly, and we should use every effort to stimulate this interest in every way possible. We must have their interest in our work and their appreciation. This society has come to be a very necessary factor in the development of this greatest of American manufacturing industries and the unqualified support of those high up in the management of the affairs of these great institutions is absolutely essential to the healthy growth and development of our society.

Value Is Great

"We must labor for a keener appreciation of the stamp of the S. A. E., impressing upon all the desirability of following those recommendations made after a careful investigation and study of the various problems that are continually arising in this work. As engineers you are devoting your full energies toward the advancement of your employers' interests and it is only right that the employer should appreciate to the fullest extent your efforts. Largely through the instrumentality of this society you are kept in accord with that which is latest in automobile engineering work. In turn you are giving to others the benefit of your experience and judgment. Impress this fact upon those for whom you labor. Impress it upon those you feel would raise the standard of the society and be benefited themselves by membership in it.

"The success of this organization is due to the fact that its membership includes many of the best engineers in this line of work; that it has accomplished much in the way of research; that it has, in a measure, received the support of those higher up in the management of automobile industrial affairs. It is now verging, I predict, upon a still greater success, as indicated by the greater activities in the various sections, the greater interest shown in the work by those who heretofore have been passive in their recognition of the society. Better work means more and better members; more financial support; the widening of our lines of activities and the keener appreciation of our work by all. The measure of our success will be very largely determined by the wisdom of the policies as laid down by our manager and the council; by the thoroughness of the work accomplished by our standards committee; by the efforts of the individual members in the papers they present for publication; by the membership committee in its endeavor to interest good material in our work; by the enthusiasm of the members in the work of the sections and by the financial support we receive.

"The detail work that has devolved upon the chairman of the standards committee has become so great that steps will shortly have to be taken to relieve this officer of a still greater portion of this work through the organization of a suitable staff to take over the details of this most important branch of our activities.

"One of the most promising indications, to my mind, lies in the very marked activities of the various sections during the past year. Enthusiastic meetings have been held by all of the several sections and much good work accomplished. These meetings while benefiting directly the members, have had an equally broad, beneficial influence on the manufacturers in the various localities, as expressed by their recognition of the work of the society.

Officers of S. A. E.

President
Russell Huff

Vice-Presidents
E. S. Foljambe
R. H. Combs

Members of Council
To Serve Two Years
David Beecroft
E. R. Hall
J. G. Utz

To Serve One Year
G. W. Dunham

Treasurer
Herbert Chase

"The Midwest section starts its career under most favorable auspices and with a full realization of its responsibility to its members, the society and the automobile industry. Its membership includes many of the most earnest workers in the society and I feel sure that the Midwest section will make a good record for itself and bring honor to the society.

"The reorganization of the Pennsylvania section is of very great importance. This section again active in the work gives the society six localized centers of activities which with the support of the parent body can be depended upon for much good work.

Navy Board Appointment

"We have been honored with the request, and have elected two of our members to serve on the Naval Department Advisory Committee appointed by Secretary of the Navy Daniels. That our society will be well represented we feel sure, and in turn we can assure this committee and our government that unqualified support of every member of the S. A. E. should their services be required.

"Along the lines of standardization, it is the desire of the society to bring about a closer relationship between the manufacturers of the United States and European countries. While we fully appreciate the many serious obstacles standing in the way of international standards, we nevertheless believe that an effort should be made toward co-operation in that direction at this time, feeling that the situation can never become more favorable than it is to-day. We have placed our views on this subject and other features of our standardization work before the United States Bureau of Standards and have assurance of its support so far as consistently possible."

Following the president, Russell Huff spoke briefly in somewhat similar strain. He said:

"I have watched the growth of this society with keen interest for many years and when I review the vast amount of good work done by it since it was organized in 1905, it makes me feel proud to be one of its members. You have bestowed upon me the highest honor the society offers to its members in electing me to the presidency for the ensuing year. I fully appreciate your good intentions in this matter and am delighted to have this opportunity of extending to you my heartiest thanks for the faith and confidence which you show in me by this election.

"There is a great work ahead of us in carrying out the comprehensive plans which have been laid down by the society in the past. While the standards committee has already accomplished wonders in the pursuit of its work, it has really only scratched the surface, as is apparent when one stops to survey the field and sees the great possibilities for standardization work which are still untouched. This standardization work is a most worthy cause, and it needs your closest attention and constant support. While it is impossible to actually estimate in dollars and cents what our standards have saved the car manufacturer, the truck manufacturer, the tire manufacturer, the parts manufacturer and last but not least the customer, we know from the promptness with which manufacturers adopt our standards, from the high esteem in which this phase of our cause is held by the captains of this big industry, and from past records that it has saved the industry and consumer millions of dollars in added convenience and lower costs.

"It is my earnest hope that we can still further increase the sphere of influence of this society. We already have six live sections and one student branch, but I believe there is room for more student branches and possibly more sections. A number of new lines of endeavor closely allied to automobile engineering should receive our attention. I have in mind the good roads movement, aeroplane and motor boat engine development, and manufacturing engineering. We also need a comprehensive library and a good engineering digest. I simply cite these few examples out of many new lines of work which this society could take up and work at for the benefit of the industry, to show the many possibilities for growth and influence."

Electric Lighting Itemized

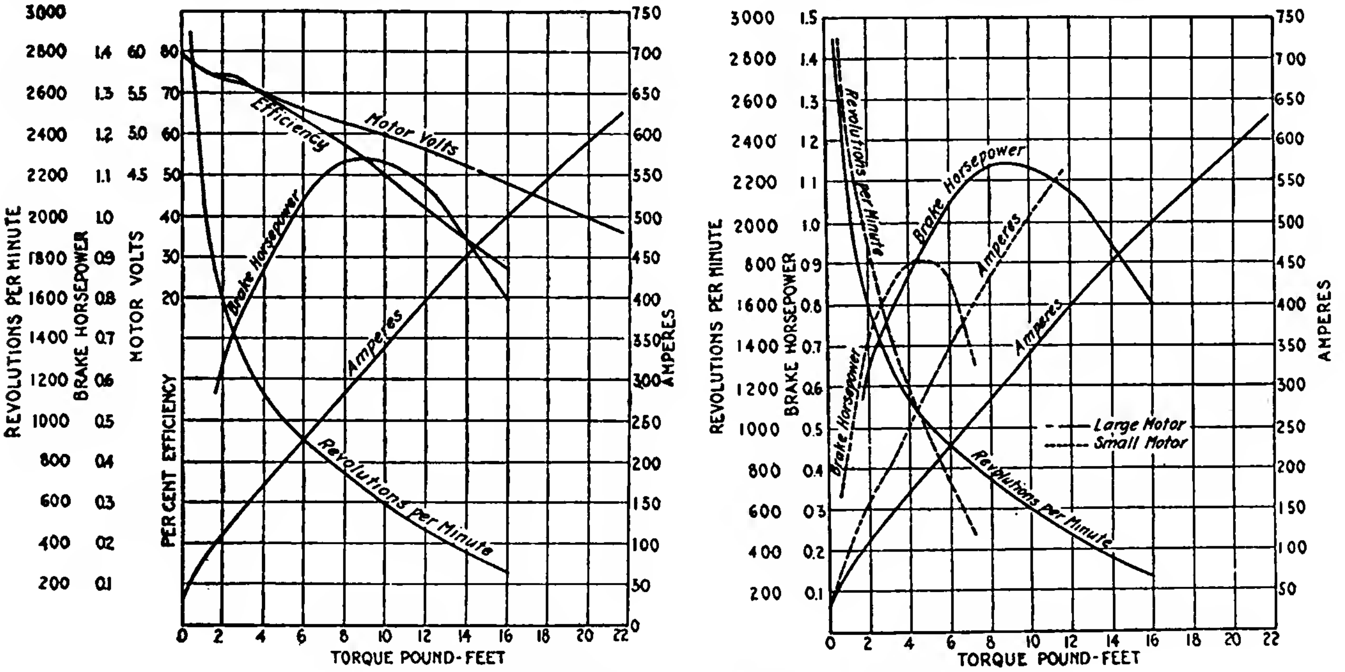
Joseph Bijur and Henry Schroeder Deal with Manufacture of Generators, Motors and Lamp Bulbs

NEW YORK CITY, Jan. 6—At the eleventh annual meeting of the S. A. E., the subject of lighting and starting was dealt with very fully by two authors who observed different sides of the manufacturing problem, these two papers making a completion of the review of automobile electricity commenced by the three other papers on the ignition systems of the day.

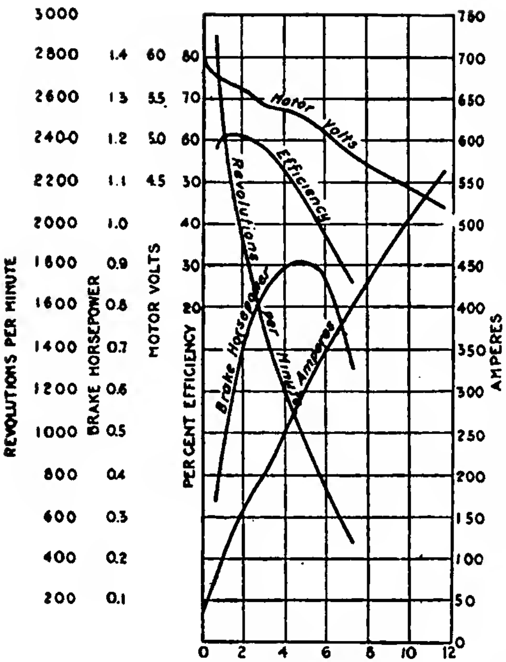
The first part of Joseph Bijur's paper dealt with the general principles of electrical equipment. The following is the second part of the paper and deals with the details of design.

Advantages of Bipolar Units

While the simplest generator to consider is a two-pole, one having a horseshoe or other shaped magnet, such generators have certain disadvantages; briefly, they have brushes 180 deg. apart, which usually means that if one brush is located so as to be accessible, the other, 180 deg. away, is necessarily inaccessible; also in such a bipolar generator the whole the flux has to pass through the entire length of the magnet circuit. If, as in a four-pole generator, we can split the flux so that we have to pass only half of it through half the length of the magnetic circuit, we can get a much more intense flux with the same amount of excitation. In such generators the brushes are 90 deg. apart at the commutator, which permits both brushes to be located in the upper or outer half-circle where both are accessible. If we consider such a four-pole generator and imagine that the exciting winding of the field magnet, known as the shunt winding, is connected across two main brushes, and that the iron always has some magnetism left in it at the beginning of rotation in the proper direction, the action will be as follows: The conductors cutting the residual flux generate a slight voltage and the sum of their added voltages appears as a difference of potential between the two brushes. Since the shunt winding is connected to these, a slight current flows through it, set up by this potential, thereby slightly increasing the excitation of the field magnet over the original residual excitation. The voltage of the armature is therefore higher, which in turn increases the field excitation, so that the voltage of the generator as a whole builds up to a value at which equilibrium is reached for any given speed of rotation. As the speed increases, the voltage of the generator rises from, say, zero to 7, at which point it is high enough to be useful in putting charge into the battery. Usually an automatic switch, excited by the generator voltage, closes at this time and connects the generator to the battery. Such a switch may be made by an arrangement of an electromagnet, having a spring-retracted armature which normally holds the circuit open, but closes it if the armature is attracted to the magnet core. The latter is energized by a fine-wire winding responsive to the voltage of the generator brushes. A coarse-wire coil of a few turns wound on the same magnet core is connected so as to be in series between the generator and the battery when the switch is closed, and its excitation by current from the generator in a direction to charge the battery, increases the pull of the fine-wire coil.



Characteristic curves for generator on left and starting motors on right



Characteristic curves of small starting motor

When the voltage of the generator falls below that of the battery, so that the battery discharges into the generator, the reversal of excitation of this coarse-wire coil neutralizes that of the fine-wire coil until the circuit is opened by the spring pulling the armature away. Assuming now that a generator and such a switch are provided, and that the switch is closed, current will pass from the generator to the battery, due to the fact that the difference of potential at the generator is higher than and overpowers the voltage of the battery. As current flows, even though the speed be not altered, the difference of potential at the generator brushes drops because the flow of current is accompanied by a resistance loss in the armature, brushes, etc., so that the increasing flow of current is accompanied by decreasing generator potential and thus equilibrium is reached. If the generator speed be now increased, a correspondingly larger current flows into the battery unless other factors enter into the operation. One of these factors is due to what is known as the reaction of the armature. The flow of current in the conductors of the armature is such that its cylindrical iron core is powerfully magnetized and opposite sides of it become strong magnetic poles. Magnetic flux is set up in this iron armature in the same way that is set up in any other iron body magnetized by a coil. With ordinary position for the brushes, this magnetic flux of the armature, or armature reaction, sets up a magnetizing force at right angle to the magnetic flux produced by the field magnets. The intensity of this cross-magnetization is proportionate to the number of turns on the armature and to the current flowing through them; that is to say, the more the turns on the armature and the greater the current they carry, the higher this cross-magnetization will be. This disurbing factor produces a resultant flux which tends to be stronger at the trailing edge of each pole and weaker at the entering edge, so that the intensity of flux is no longer distributed evenly over the air-gap between pole surface and armature, but is crowded or denser near one side of the pole than the other. In addition to this distortion, some of the armature reaction is directly opposed to the main magnetic flux of the field magnet and opposes and weakens it; thus it comes about that the rising current flow through the armature is accompanied by a distortion and weakening of the magnetic flux, which originally produced the potential from which the flow of current arose. Therefore, when current is taken out of an armature, there is a drop of potential from brush to brush, caused partly by resistance drop in the armature and partly by a loss of effective magnetic lines resulting from armature reaction.

Regulation of Generators

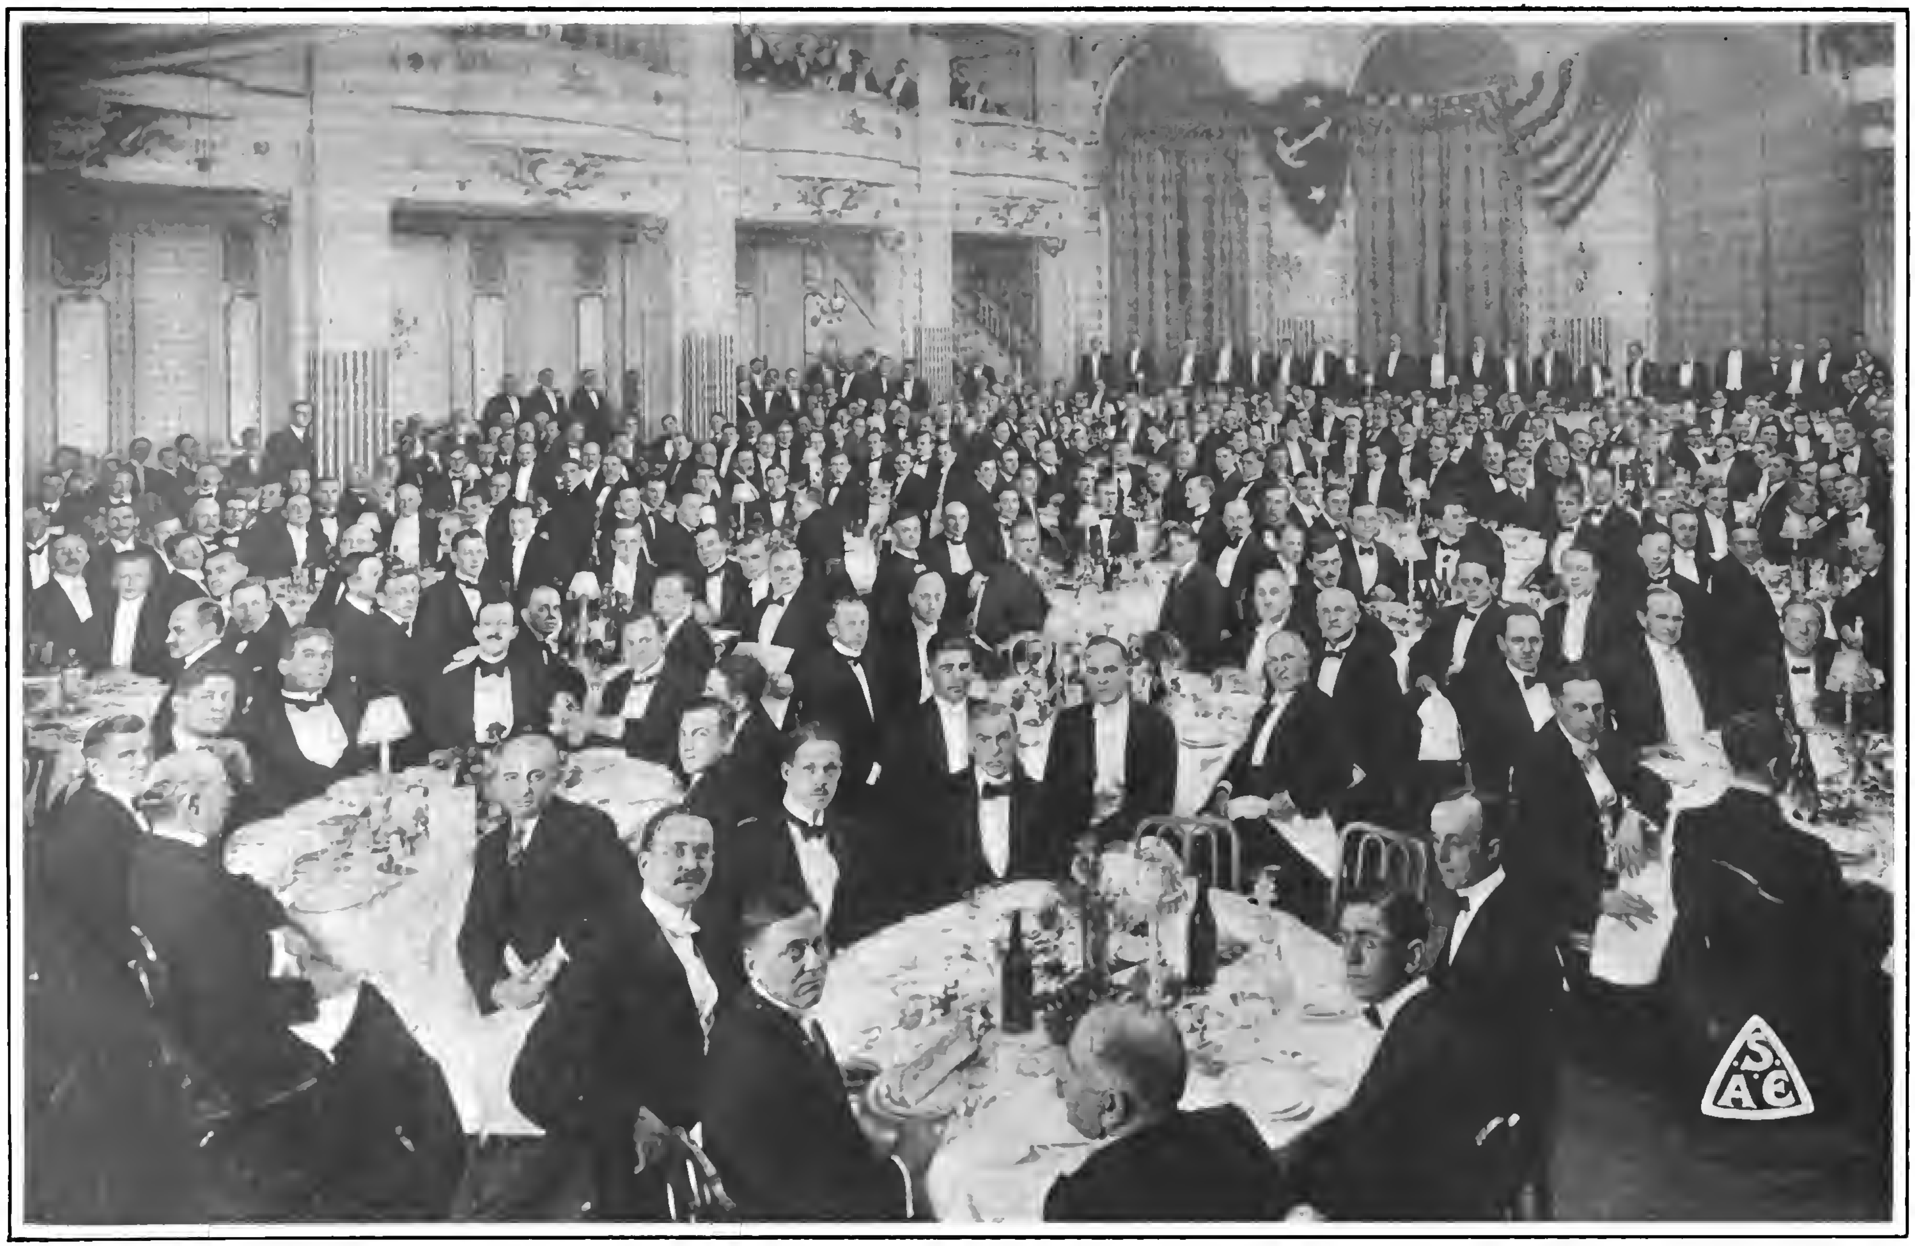
With increasing speed and therefore increasing current, we do not reach the speed at which some kind of regulation must be used until the current becomes excessive, in spite of the factors which tend to hold it down. From this point on we will either have excessive current or have to do something to diminish the useful flux which the armature conductors cut. It is conceivable that we might use a generator having so many turns of small wire and such a poorly arranged magnetic circuit, that the resistance drop of the armature and the blowing-out of the magnetic flux might alone reduce the voltage with rising speed to such an extent that the generator would not overheat and burn up. But such a machine has losses which, while helping to save it from heating at higher speeds, prevent it from giving anywhere near a good output at low speeds. Therefore, we will continue to consider the usual generators having relatively few turns on the armature and these of ample cross-section. With such a machine, to prevent a rise of voltage in the higher ranges of speed, we employ some method of weakening the magnetic field. In a general way the field is weakened by some peculiarity in the construction of the generator, such that increasing current decreases field excitation. This is known as inherent regulation. If instead, the generator itself be of the plain shunt-wound type, the weakening of the field is accomplished by the action of a separate regulator responsive to either current or voltage, or both, this regulator being arranged to vary the strength of the exciting field current. This might be termed "regulator regulation."

With inherent regulation it is difficult to make a construction in which the control of the machine is responsive to anything but current in some circuit, that is to say, either in the dynamo output circuit or in the battery branch circuit. To make such a machine regulate in response to its electrical potential alone, is so difficult or costly that machines of this type have not come into commercial use. On the other hand, when a separate regulator is employed, the regulator can be constructed to control the generator in response to either generator current or generator voltage independently of the generator current. Without at this time referring to the exact differences between the result when the generator is regulated purely in response to the voltage, and the result when it is regulated purely in response to current, it can be stated that the regulation in response to voltage alone has certain very attractive features. As just pointed out, this regulation cannot be accomplished with reasonable space and cost without using a separate regulator. On the other hand, if a separate regular is used, it can be made responsive to voltage alone in substantially the same space and at only slightly higher cost than if made responsive to current. Under these circumstances there is a tendency to regulate according to voltage whenever the circumstances warrant the cost of an independent regulator; whereas, if it is satisfactory to employ regulation responsive to current, this can be obtained without the use of a separate regulator and therefore without its cost and added parts; and in some respects the current regulation that can be had from certain types of inherently regulated machines, such as third-brush generators, is preferable to even the regulation obtainable from a separate "current" regulator. As a whole, the indication is that where the electrical load is large and the machine should be able to give out high amounts of current to take care of this load and to recharge a battery which has been subjected to this load, voltage regulation is desirable, even though it is attained at a somewhat higher cost. Where, on the contrary, the lighting load is not very high and the starting load and the drainage from standing idle constitute a larger factor in the total current consumption, current regulation can be employed to good advantage, especially when it is considered that generators for the purpose can be manufactured at less cost.

Factors Governing Size and Speed

Regardless of the method of regulation, the generator size and speed must correspond to the conditions of the car to ensure adequate current supply.

(To be concluded)



S. A. E. annual dinner held Jan. 6 at Hotel Plaza, New York City. The number present eclipsed all previous records, reaching a total of 550. Addresses were given by Secretary of the Navy Daniels and Major General Wood, U. S. A., Commander of the Department of the East.

EIGHTH annual banquet of the Motor and Accessories Manufacturers' Association, held on Wednesday evening, Jan. 5, at the Waldorf-Astoria, New York City. This was the largest gathering in the history of the association, 450 being in attendance. There were no speeches whatever, with the exception of President Lovell's announcement to the effect that the evening was to be entirely devoted to sociability and the enjoyment of the repast and the cabaret entertainment provided, which lasted till nearly midnight.

ANNUAL banquet of the National Automobile Chamber of Commerce, Inc., held at the Waldorf-Astoria, New York City, Tuesday evening, Jan. 4. This was one of the largest gatherings of automobile manufacturers in the history of the chamber, 300 men being present as representatives of the majority of the industry. As Charles Clifton, president of the chamber, was absent, owing to illness, Wilfred C. Leland, of the Cadillac company, presided. Senator Gore, of Oklahoma, was the only speaker of the evening, and his subject was "Preparedness," which he discussed from its various angles and in different phases. The menu for the banquet was in the form of a stock certificate for 1000 shares in the Blue Sky Motor Car Co., incorporated under the State of Collapse. Another novelty was the decorating of John N. Willys, Harry W. Ford, George Kissel, and John F. and Horace E. Dodge with huge burlesque medals for various accomplishments in the manufacturing field. The medals were hung about the necks of the recipients by red ribbons.

The History of the American Automobile Industry—12

Increased Activity in Steam Vehicles Follows Pecqueur's Invention of the Differential and Modern Type of Steering Gear—Adverse Laws Smother Development in England

By David Beecroft

FOLLOWING the broad inventions of the Frenchman Pecqueur in 1828 of the differential as used to-day, of the modern design of steering gear and also the two-speed planetary gearset, there was a very general increase in the wave of steam activity. Pecqueur did much to blaze the road of future progress. His startling inventions set hundreds thinking and gave an atmosphere of practicability to the steam vehicle that it had not previously possessed.

In 1833 Richard Roberts patented in Great Britain the balance gear or differential shown by Pecqueur in France in 1828. This gear was also used by F. Hill, who in 1840 built vehicles weighing 4 tons with speeds of 12 to 16 m.p.h., which were known to make 20 m.p.h. on special occasions, and 128 miles per day over difficult roads were accomplished by Hills' coaches, which was twice as fast as horse coach speed, and the expense was claimed to be but half as much. His vehicles used wheels 6½ ft. in diameter.

It is often said that any new device may know it has arrived when the joke makers and comic artists take it up. So common did the motor vehicles become in this early period that George Cruikshank, London, who has been called the father of caricature, based a number of his funniest drawings on the new vehicle, about 1828 to 1830.

John Scott Russell, in England, best known as the designer and builder of the Great Eastern steamboat, made a small model steam automobile quite early, built a half dozen full-sized soon after, and in 1834 furnished the vehicles for a steam carriage company coach line. These vehicles carried from thirty to forty passengers. He attempted to improve the steam boiler, by making it light and staying its walls together, some of his boilers having as many as 1300 stays.

Red Flag Legislation

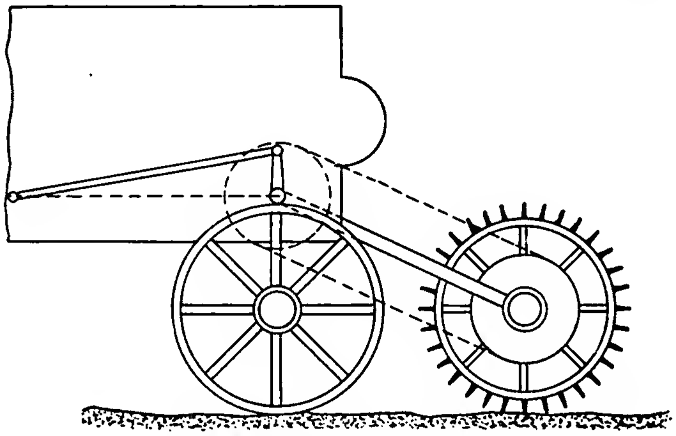
The high tolls imposed on motor vehicles in England, the constant objections of the vested interests represented by the coachmen and horse users generally, and finally a law which compelled each steam automobile to be preceded by a man carrying a red flag—all worked to suppress this promising movement with the result that although some inventors kept working, England practically disappears from the development of the automobile about 1845.

Several names appear in France keeping alive the movement there, among them being Dietz, who built an eight-wheel drag about 1834, driven by steam.

Doubtless political events had much to do with this cessation of mechanical vehicle development, but whatever the cause the steam vehicle for common roads languished. Occasional workers could not suppress their ambitions, so sporadic attempts were frequently found, but the great wave had subsided, and for the next 25 years little progress was made.

Begun as a carriage, developed into a coach, it diversified into the traction engine on the common road and the locomotive on rails. All the elements of the modern automobile that could be adapted to the traction engine or the locomotive had been developed to a fair degree of perfection during this period, so it is now possible to confine our consideration more closely to the light steam engine, to the velocipede or bicycle, to the gas engine, and to what may be termed carriage construction.

In spite of the drastic tolls and restrictive legis-



REAR-END PROPULSION

Many steam inventors were firm in their belief that some form of toothed wheel mounted back of the rear axle of a vehicle would prove the most satisfactory means of propulsion, many of these devices appearing between 1800 and as late as 1860. These rear driving wheels, resembling the paddle wheel on a Mississippi steamer, were driven by chain or belt, according to the ideas of the inventors lation and the rapid acceptance of the locomotive and traction engine, the automobile idea did not wholly die. Occasional work in spite of the restrictions kept it alive, and about 1860 there was another wave of popularity, principally marked by the work of Rickett of Buckingham, who built a number of passenger locomotives, beginning about 1858. Most of these were of the type shown, having three wheels, of which the rear wheels did the driving and most of the load carrying. They weighed 3000 lb. and carried 1200 lb. of water and 300 lb. of coal. The boiler carried 130 lb. of steam pressure and fed a two-cylinder engine. At the rear was a place for the stoker and the forward seat was wide enough for three or four.

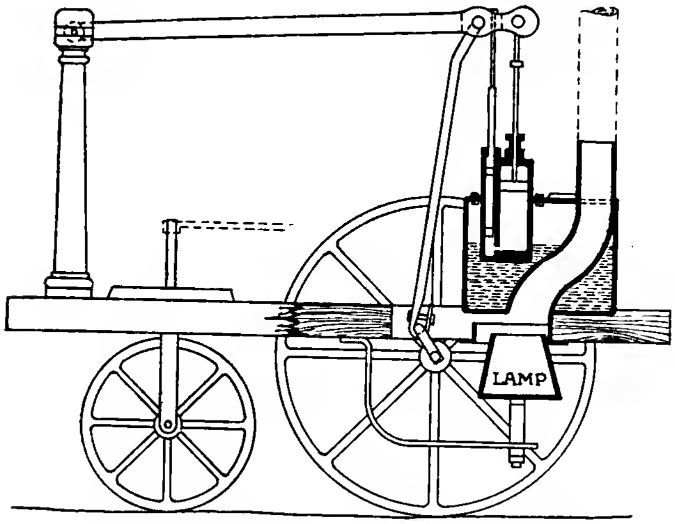
A 10-mile speed was common and grades of 10 per cent could be climbed by using the speed gear. One of these vehicles made 150 miles in 2 days in a very mountainous district and thoroughly proved its practicability. Rickett first used chains and sprockets but later used spur gears and finally connected the pistons direct to the driving wheels, as in a modern locomotive.

Steam Tractors in 1858

In 1858 Adamson & Co. of Manchester built for a customer a tractor for the purpose of hauling an omnibus. It had three wheels and ran at 8 m.p.h. Nine years later it was still in existence and had a race with a machine made by J. W. Boulton of Ashton. Boulton had built several of these and this one had a record of 90 miles in a day, carrying six to ten passengers and making no stops except for water.

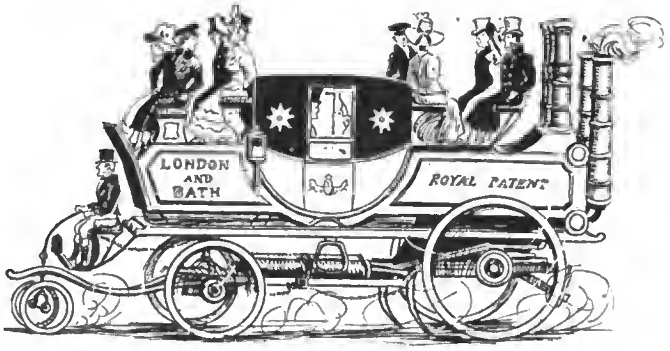
W. O. Carrett made a steam carriage in 1861 which was shown at an exhibition in 1862 and afterward sold to a London man who drove it about 800 miles, mostly at night to avoid conflict with the law. Later he rigged it up to resemble a fire engine and even provided firemen's suits for the passengers by which means he escaped interference for some months, but eventually had to give it up. It had a locomotive type boiler, carried 175 lb. of steam, the engine was geared to the rear axle which had a balance gear.

J. H. Knight constructed in 1868 a small two-cylinder vehicle weighing 3200 lb. and capable of 8 m.p.h. Its capacity was three passengers and the stoker, and it carried water for one hour and coal for three. It was afterward converted into a traction engine.



MURDOCK'S MODEL OF LOCOMOTIVE 1784

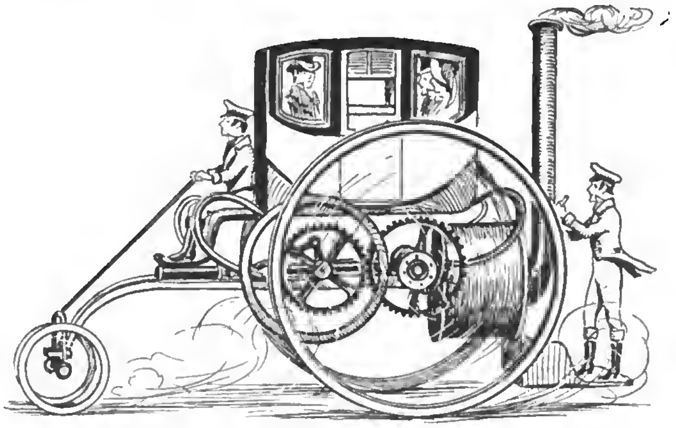
One of the early locomotives was that of William Murdock, a Scotchman, who was closely associated with James Watt in the development of the steam boiler. In 1784 Murdock built a small working model of a high-pressure locomotive engine illustrated herewith, which was satisfactory in performance. The lamp was located directly below the water boiler. In it is shown the vertical cylinder, in which is a piston connected to the overhead walking beam. From this beam a long connecting-rod coupled direct with a crank in the axle. It is interesting to note that Watt, although reposing the utmost confidence in Murdock, had no faith in the development of the steam carriage at that time and wrote that he was extremely sorry that Murdock was devoting his attention to it rather than attending to business which Watt considered of greater importance



GURNEY'S STEAM COACH OF 1827

One of the leading British inventors of steam vehicles was Goldsworthy Gurney, born in Cornwall 1793, and educated as a doctor. For several years he was a lecturer on chemistry and was a leading spirit in the highest scientific circles of his day. Besides turning his attention to steam vehicles he invented the oxy-hydrogen blowpipe, the limelight, and the steam jet for ventilating mines. He was responsible for the first lighting and ventilating system used in the British Houses of Parliament

His most famous steam coach, as illustrated herewith, was running in 1827. He carried twenty-one passengers, six inside and fifteen on the outside or top seat, some of which were in front and some in rear. It was a six-wheeler with the four main wheels practically the same as used on a horse-drawn vehicle and with two small steering wheels in front, which were guided by the operator, who sat very low in front with throttle and brake levers close at hand. This vehicle made a run of 6 miles in 35 min. and was able to climb hills at 5 miles per hour



TREVITHICK'S STEAM CARRIAGE OF 1803

To Richard Trevithick belongs the credit of producing the first practical steam vehicle illustrated herewith. He began his work in 1802, and had this vehicle operating the following year. His was the first attempt to provide a form of carriage for the passengers, although it remained for Griffith to develop what is known as the first comfortable vehicle for passengers. Trevithick made a number of journeys in this vehicle, averaging 8 or 9 m.p.h. for distances of 4 or 5 miles

The Rostrum

Says Designers Disregard Drivers' Comfort

EDITOR THE AUTOMOBILE:—During examination of cars at the New York show, I was particularly struck by the utter disregard of the driver's comfort as far as controlling the car is concerned. Most of the control levers are to be reached only with effort; and the hand brake lever frequently is at such a distance that one must leave one's position behind the wheel to reach it—or else pull it on with the foot.

Of course, this is caused by subordinating accessibility of the levers to ease in getting into and out of the seats. However, is it not more important to be able to control the car?

While modern trend toward eights and twelves may make gearshifting really unnecessary, all good drivers need the handbrake both for hilly city driving and fast driving anywhere. Hence, it should be easily reached, preferably without leaning forward to do so. A glance at the strained positions of passing drivers, some with both hands at the top of the wheel, others with elbows high and in similar grotesque positions, constantly requiring excess effort and sacrificing control, shows that it is just as impossible to make one car to fit everyone as it is to make one suit for all sizes of people. It is not expected that the same shotgun should fit everyone. On the contrary, makers recognize the variations in human architecture and supply corresponding variations in gunstocks to fit them. It is about time for the public to demand cars that are made to fit various types; shorts, and longs, stout and thin.

That this will add to safety is certain. That it will increase comfort and enjoyment is sure.

Deming, N. M. L. D.

Needs New Valve Tappets and Guides

Editor THE AUTOMOBILE:—The valve tappets on my Hupmobile model H-32 pump lubricating oil out of the base which is a big waste and a considerable loss.

Please advise if the valve spring covers could be made oil-tight to prevent this waste of oil, and if so, please show how it can be done.

Abbeville, La. S. C.

—It is believed that studs could be so arranged and a cover made with a cork gasket whereby the valve spring compartment could be made oil tight, similar to the construction of the model N Hupmobile. However, a change of this kind has never been made, and the Hupmobile company is not in position to furnish parts, or prints showing how it could be done. It is suggested that you install new valve tappets and guides, to eliminate leakage of oil.

Clutch Brake is Set Too Tight

Editor THE AUTOMOBILE:—What causes free leakage of much oil from the transmission box of the latest model 32 Hupmobile and how may it be corrected? The oil leaks only after the engine has been in operation, will stop after a few ounces, more or less, has been lost and does not leak from the union of the propeller shaft housing but rather from the union between the transmission box and the universal joint housing.

2—What causes the clutch of the model 32 Hupmobile to stop the engine when the clutch is disengaged in effort to shift gears, and how may this be corrected?

When the throttle is most open and the engine is running at a speed of about 2500 r.p.m., it is possible to shift into low gear without killing the engine. The machine has been in use long enough to wear off the new but while this feature is better yet it gives much trouble.

3—How is oil prevented from entering the starting switch on the model 32 Hupmobile and how may the apparatus be inspected to see that oil does not enter same?

4—When the clutch springs of the model 32 Hupmobile are so near the flywheel that a wrench cannot be inserted how may the springs be adjusted? Some of the springs are all right and some are as far to one side as some are to the other.

5—How much play should recoil straps have to insure easy riding?

Graysonia, Ark. F. M. B.

—In the first paragraph of your inquiry you speak of an oil leak from between the transmission box and the universal joint housing. The model 32 is not constructed along these lines.

2—The clutch stalls the engine because the clutch brake is set too tight. This may be corrected by the clutch brake adjustment. This applies also to the latter part of the second paragraph in which you speak of running your motor in high speed and finding it impossible to shift into low gear without stalling the engine.

3—The switch is so constructed that the housing over the front end prevents oil or dirt from getting into the switch contact. No trouble is experienced from this source.

4—The Hupmobile factory furnishes the owner a special wrench with each car which is to be used for adjusting the spring tension in the clutch plate. This is a combination wrench and may also be used on the spark plugs.

5—It is impossible to answer this as you do not state what kind of recoil strap it is. The Gabriel Snubber has its adjustment made by the manufacturer of same and is set before being shipped.

Wants to Change Seating Arrangement

Editor THE AUTOMOBILE:—I would like to ask your advice in regard to changing the seating on my four-passenger 1912 Cole 4-40. It has too much room in front and not enough in the rear although it has 122-in. wheelbase. I would like to install two auxiliary seats.

1—How is the front seat fastened to the body, and would it be practical to move it forward?

2—The car is equipped with Gemmer steering, and could this be shortened? Would it do to move it up or is there a better way to change the length of the column?

3—As the gear shifter will be all right, is there anything else I might have to contend with?

4—Would this make any difference in the riding of the car?

Mishawaka, Ind. W. G.

—The front seat is built into the bodywork, including the sills and the side panels and it really is not a practical thing to do to cut this seat out and build another seat into the body farther forward. However, this seat could be cut away from the bodywork and two seats could be set in the front part bolted to the floor and, if the owner desired, could be made adjustable, backwards and forwards.

2—Shortening the Gemmer steering gear is practical but it should be done by a first-class mechanic. It is not recommended that the gear be moved forward as it would entail a shortening of the fore and aft drag link, which is bad and it also would necessitate changing the front toeboard pedal arrangements, etc.

3—If you are satisfied with the gear shift locations, there is nothing else which would interfere with the body change.

4—The addition of the auxiliary seats and two passengers will evidently make the car ride easier but it will be necessary to add rubber bumpers on the rear end, to limit the play of the springs as they were not originally designed to carry this extra load.

Removing Carbon by Oxygen Satisfactory

Editor THE AUTOMOBILE:—I have two cars, a Buick six and a 1915 Ford and the young man who works for me has an oxygen carbon burning outfit which we have used on both to remove carbon, which process he learned in the Buick repair department. We had occasion to take the Ford to the local garage to take up the bearings and I noticed that the cylinders were all scored or all had longitudinal scratches on the walls which surprised me greatly, as the car has run but 700 miles and been carefully lubricated. Both the garage man and his assistant claim that every Ford or other car that they have observed that have had the process used are scored, especially Fords, finally admitting that he would not condemn its use except on a Ford.

Fenton, Mich. B. G. McG.

—If the oxygen burning machine is used in the proper manner by one thoroughly experienced in its manner of operation, it is not seen how it would affect these motors any differently than it would any other type of power plant. It is hardly believed that the scored cylinders have resulted from that work, although it is possible that the scoring dates back to the accumulations of carbon before it was removed, or perhaps the motor was run at some time or other with insufficient oil. It has always been the contention that the best way to remove carbon is by removing the head and scraping the deposits from the inside of the head and the tops of the pistons, as in that way only is it possible to give attention to the seating of the valves, which is of prime importance to the satisfactory operation of any motor.

Fitting Top to Kline Roadster

Editor THE AUTOMOBILE:—Kindly advise me where I could have a one-person top placed on my Kline roadster, model 1912, without sending it to the factory which is now located at Richmond, Va.?

Lopez, Pa. M. G.

—Any top maker in your vicinity can do this for you as the one-person sockets are now made by several forging companies. The top maker fills in a measurement blank and the proper sockets are then sent. The Kline company is supplied by the Cortland Carriage Goods Co., Cortland, N. Y.

New Cylinders and Pistons Needed

Editor THE AUTOMOBILE:—I have a 6-66 Pullman 1913, cylinders 4½ by 5½. At times there is a tap in the middle pair of cylinders. Not all the time. Will run along for miles without a tap, then tap for miles. It will tap going up hill but not on the level and then again it will not tap going up hill. Have had the motor taken down but could find nothing out of order, but have been told it was a side thrust or slap of the cylinder. It was there when the car was new and was told it was the tappet, but now I know better. I have come to the conclusion that a pair of cylinders does not get the proper lubrication. What would you advise? I am going to have new piston rings put in all the pistons and possibly a new middle block and pistons in place of middle pair of cylinders.

The later models of the Pullman 6-66 have a bore of 4¼, or 4⅜ by 5½, which made the middle wall of the pair of cylinders thicker. If I should put a pair of cylinders 4⅜ by 5½ what will be the result? The reason the bore of the later models were made smaller was to increase the thickness of wall between each pair of cylinders. I noticed that when the motor was taken down, the wall was thin and just a perceptible crack crosswise of the cylinder and below the water line.

Dover, N. H. H. G. H.

—You are correct in stating that the tap is not in the plungers, but lies in the cylinders and pistons. In 1913 the bore was changed to 4⅜, thereby increasing the walls of the cylinders which eliminates, to a great extent, the warping of them. The only real solution for this trouble that can be given is to have a complete set of 4⅜-in. cylinders and pistons placed in this car. It is not possible to use a pair of these and having the other two pairs 4½ in.

Use of Kerosene in Lubricating Oil

Editor THE AUTOMOBILE:—Will you please inform me whether kerosene would be injurious to the motor, commutator or magneto of the Ford car when used with lubricating oil, in the proportion of 15 to 25 per cent kerosene?

I have been using such a mixture for four months with a great deal of satisfaction. Before beginning the use of kerosene with the lubricating oil I had considerable difficulty in starting the motor when cold, and also experienced a great deal of trouble with carbonized spark plugs, cylinders and valves. I had the carbon removed from all parts of the motor before beginning the use of kerosene, but this did not remove the difficulty of starting the motor, besides the spark plugs would become carbonized in a few hours. I began the use of kerosene with the motor in bad condition, but the misfiring soon disappeared and I have had no trouble in starting the motor at any time. The car has been run 1500 miles since the carbon was removed from the motor, but it still functions like a new motor.

Washington, D. C. R. W. C.

—Kerosene can be used in some ways with good results, in the care of the Ford motor. However, we would not recommend mixing it with the motor lubricating oil. It is a good plan to use a 25 per cent mixture of kerosene with the commutator lubricating oil in cold weather so as to thin the oil sufficiently to prevent congealing on the commutator contacts which causes difficult starting of the motor. Also, we recommend draining the old oil from the crankcase approximately every 3000 miles, washing out the case with kerosene oil, draining that off and replenishing with fresh oil. It also is entirely practicable to remove the spark plugs when the motor is warm and put in a little kerosene in the spark plug holes which relieves carbon deposits to some extent.

In your case you are using a very heavy motor lubricating oil which, congealed between the clutch discs, causes trouble in starting the motor, and by putting in the kerosene you have thinned the oil sufficiently to eliminate that difficulty. Our idea is that the trouble can be traced directly to the grade of oil being used rather than to any condition which existed in the power plant. Taking this into consideration you will readily see that for general use it would not be practicable to put in kerosene with the motor lubricating oil, and if a proper grade of oil were used the kerosene would thin it entirely too much. You had better call at the Ford branch in your city and obtain oil that is adapted to the motor and that will enable you to discontinue your present practice.

Truck Design Shows Many Changes

(*Continued from page* 59)

remedy for this has been the division of the shaft at its middle, the fitting of three universals and a center bearing. An alternative to this has been the substitution of a tube for the usual shaft, the tube being much stiffer for its weight and strength than the solid shaft. The duty on the universals in long tubular driving members, however is more severe and so for success, rather more robust joints are required.

More Reserve Power in New Motors

This smaller and more compact unit power plant does not by any means signify that the truck of 1916 is not so powerful as that of 1915. On the other hand the efficiency of the motor and driving units has increased to such a degree that although the formula horsepower would show a falling off of several per cent, this would not be by any means a fair comparison. The motors of 1916 operate at higher rotative speeds following the same trend as in passenger car design. They are geared lower and the power curves of the motor extend to a higher peak than ever before and the result is that the motor has a greater reserve power for use on hills. The fact that the miles per hour speed allowed by the governors is just the same as last year shows that there is a greater factor of safety than ever before due to the fact that the trucks are not using in their regular duties anywhere near the ultimate horsepower of the motor. This is advantageous in two ways: first, it gives a greater reserve power for hills and rough roads and secondly, it increases to a notable extent the life of the vehicle.

Disk Clutch Gains 20 per Cent

In the various units which go to make up the drive of the truck there has been no change, shaft drive excepted, which is more noteworthy than the increase in the disk type of clutch. This has risen in one year from 28 per cent to 48 per cent. In other words whereas a year ago about one-quarter of the trucks had dry-disk clutches, at the present time they are fitted on nearly one-half the chassis. The cone clutch has fallen off from 42.2 to 26.3 and the disk in oil has dropped from 17.8 to 13.1. The fool-proofness of the dry-disk design and the ease with which it can be cared for are the two points that have recommended it to the designer of motor trucks, and it is probable that the use of this type of clutch will continue to grow in popularity. This is another trend which reflects that of the passenger car industry where simple clutches have come to be in great demand.

One point in which the tendency in truck design varies widely from that of passenger car practice is in the use of the four-speed gearbox. Whereas in the passenger car the four speeds have proved to be unnecessary with the lighter car loads, the higher-speed multi-cylinder motors, etc.; in the truck field, with the increasing capacity tendency there is an inclination to favor four speeds.

The development of the trailer, too, has resulted in designers looking with more favor on the multi-speed gearset, for the increased inertia imposed by the trailer requires an additional starting reduction. On hills, too, the additional load calls for a lower hill-climbing gear. The steps also need to be closer together, as they are in the four-speed design.

The result is that the percentage of trucks equipped with the four-speed gearbox is higher than it was for 1915. The respective percentages are 11.5 and 19.9 for 1915 and 1916. The difference in these percentages is made up by the drop in the three-speed gearbox which has fallen from 82 to 76.6. The use of the two-speed gearset is falling off.

Although the gear ratio average in 1916 is very slightly higher than that of 1915, a broader view must be taken than that which would be suggested by the averages of 8.66 to 1 and 8.75 to 1 which represent the practice for two years.

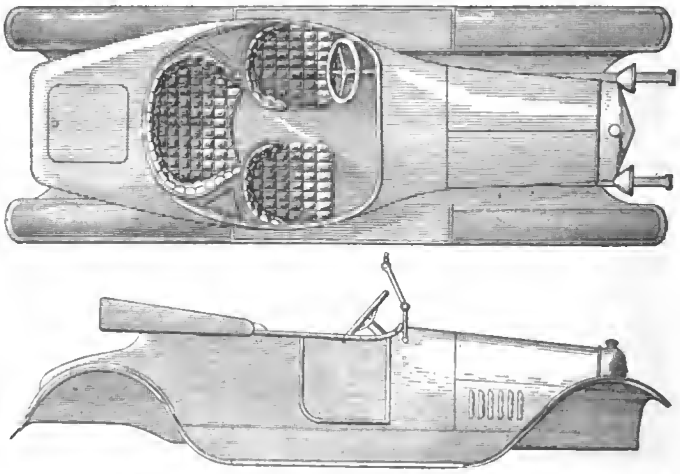
Simplification a Factor

It must not be understood that with the greater capacities the truck of 1916 is a heavier and more unwieldy vehicle than that of 1915. The contrary is the case and although the pay-load may be higher the weight of the chassis itself is, on the whole, less. This is due to the tendency toward simplification which is reflected in many ways throughout the car. The elimination of parts due to the employment of spring drive is a very good example of this. Last year the percentage of trucks which transmitted the drive through the springs was twenty-three. For 1916 this has increased to 47.3. The torsion strains are taken through the springs on 81 per cent. Practically every truck which takes the final drive through the springs takes the torque in the same manner and the percentage figure, for those using the spring drive, will hold good for Hotchkiss drive also.

Semi-elliptic springs seem to be the most favored way of carrying out the suspension. They are used on 88.4 per cent of the rear installations and 96.7 per cent of the front. Springs in general are longer and the suspension of the truck is easier on load and driver as a result.

Apperson Gets Design Patent on Clover-Leaf Body

NEW YORK CITY, Jan. 10—In view of the large number of three- and four-passenger roadsters of the clover-leaf type on the market, special interest attaches to the design patent on a body of this description granted to Elmer Apperson, Kokomo, Ind., and assigned to the Apperson Bros. Automobile Co., of that city. This design patent, which was granted Jan. 4 on an application filed Aug. 6, 1915, is No. 48,359 and its term is seven years. It specifies "a new, original and ornamental design for automobile bodies," as shown in the accompanying illustration, the construction being a streamline body for a left-steer chassis, the passenger compartment having a driver's seat and another seat with an aisle between them leading to the seat for one or two passengers in a horseshoe-shaped compartment behind the two front seats.



Plan and elevation of three or four-passenger body covered by design patent granted to Elmer Apperson on Jan. 4, 1916

74,000 Trucks

THE production of motor trucks in America last year reached a total that is within sighting distance of the 100,000 mark. Of this large number a third were exported, but not all of that third went to do war work. Probably war purposes consumed about a quarter, and the difference represents trucks put to industrial purposes abroad.

Without question the most important phase of this export business is the part that is not government orders. Owing to the condition of the factories of Europe the American truck manufacturer has been able to get a decided footing in Great Britain, in France and in the many other parts of the world to which these two countries have been sending their trucks hitherto. These markets are not won completely, and it remains for the American makers to use their advantage to the utmost; they have their first success, and if it is to lead where it ought to lead they must push ahead just as fast as they are able.

With a home demand exceeding the supply and a foreign demand still more loudly clamoring for more trucks, 1916 can be faced with the probability that all previous production figures will be eclipsed. In a year from to-day the 74,000 that now looks so large ought, by rights, to have shrunk to very little in comparison with the 1916 output.

Settling Ignition Questions

HOW much stronger a thing is personal preference than scientific experiment; how difficult, in the face of prejudice, is it to get a scientific demonstration that is convincing to everyone! To-day nobody can say that the automobile ignition question is settled, nobody can see that the S. A. E. discussion has really brought us any nearer to determining the destiny of the magneto.

Taking the papers presented, of which each represents the conclusions of scientific research, it is obvious that the data collected is insufficient absolutely to settle the matter, yet it ought to be possible to *prove* the truth or otherwise of the conradictory contentions. Of course no laboratory experiment will settle a question complicated by commercial considerations, and that probably is the reason why it has taken so long to get a final ruling on the magneto-battery controversy. On and off, we have had it with us for twelve years now.

Tires Up 20 Per Cent

THE rise in the price of tires is one of those things which is always liable to happen in times of great disturbance. Practically everything the tiremaker needs costs more to-day that it did a short time ago. Rubber is up because of fear. Fear that the Suez Canal may be closed, fear that boats may be lost with valuable cargoes, fear on the part of both the plantation owner and the ultimate buyer. The reason for the present price of rubber is psychological, but it is also natural and not unreasonable. That the price will soon drop again is the general belief.

But rubber is not the only thing in tires which costs more. Certain compounds of zinc which are needed in the vulcanizing process are actually difficult to get, owing to the absorption of certain sources of supply by war. Zinc itself is short throughout the United States, so short that copper is getting to be cheaper than brass for some purposes. Cotton, too, of the special grades used by the tiremakers, is dearer and labor is certainly no cheaper, so if there is nothing to really account for the rubber price ruling to-day, there are plenty of things to explain the price of tires. Consumers can, however, rest with an expectation that the present prices are but temporary.

That rubber must cheapen again soon is as nearly certain as anything can be in connection with the romantic tropical product, and if rubber falls substantially the price of tires cannot but follow the fall.

Roadster Development

THE development of the roadster has suddenly taken a stride ahead in the past year. It was not long ago that the tendency of many makers was to drop the roadster from their lists. The new sociable seating giving three- and four-passenger capacity has again, and justly, put these vehicles in a position where they appeal to the popular fancy.

N. A. C. C. Cross Licensing in Force

Agreement on Exchange of Shop Rights of Members on Patents Effective Jan. 7

NEW YORK CITY, Jan. 10—Perhaps the most important event that occurred during show week in this city last week was the formal enforcement of the cross-licensing patent agreement among the members of the National Automobile Chamber of Commerce, Inc., which agreement went into force on Friday, Jan. 7. This cross-licensing patent agreement has been under organization for over a year, and by it the members hope to reduce very materially the amount of patent litigation among members.

Eighty of the ninety-seven members of the chamber have signed this voluntary agreement, by which they agree to give to the other seventeen members of the chamber shop rights on their patents. This agreement gives the other seventeen members six months in which they can enter into the agreement and share in the privileges.

Up to the present moment the N. A. C. C., through its able patent department, has examined and verified 353 patents controlled by the eighty companies that have entered into the voluntary agreement. This work of examining and verifying is still going ahead, and it is anticipated that well over 500 different patents will be represented in the cross-licensing agreement.

Two Classes of Patents

By the present scheme it does not mean that all patents owned by the eighty companies signing the agreement are pooled among the said companies and shop rights granted, but rather that patents are divided into two grand classes as follows:

Class A—Fundamental and basic patents, and particularly fundamental patents on motor trucks. These patents are not included in the cross-licensing agreement in that the purpose of the agreement is not to take away from any concern the value of basic and fundamental patents.

Class B—Patents relating to the general development of the industry are covered in the agreement. These patents have more to do with detail inventions rather than basic or fundamental patents.

New Detroiter Six for $1,098

DETROIT, MICH., Jan. 11—The Detroiter Motor Car Co., this city, has brought out a new five-passenger touring model called the Detroiter Six-45 and selling at $1,098. The Continental unit powerplant has block cylinders, which are 3¼ by 4½, and which have detachable heads.

Other features are: Auto-Lite starter with a Connecticut distributer separate from the generator with a variable spark, three-quarter floating axle, the differential being carried on ball bearings, and the wheels on roller bearings. Lubrication is force feed with pressure gage on dash. The clutch is multiple disk; the drive is Hotchkiss through vanadium-steel springs; tires 33 by 4; wheelbase 118 in. Equipment includes one-man top, windshield, Stewart speedometer, gasoline gage, electric horn, tire repair kit and tools.

Ford to Shorten Working Hours and Increase Wages

DETROIT, MICH., Jan. 12—*Special Telegram*—It is expected that important changes will be made in the working schedules of the Ford Motor Co. to take effect Jan. 15. Six hours will constitute the day's work instead of eight. There will be four shifts of six hours. Along with this shortening of hours, the minimum wage will probably be 50 cents an hour and those men now receiving $5 a day will be given $1 an hour, thus increasing their wage to $6 a day. It is likely that the system will be applied to all the Ford assembling plants and branches.

20,405 Cadillacs in 1915

DETROIT, MICH., Jan. 7—Cadillac cars having a value of between $41,000,000 and $42,000,000 were sold by the Cadillac Motor Car Co. in 1915. Exactly 20,405 eights were shipped between Jan. 1 and Dec. 31, 1915. A good many more should have been shipped before the year ended, but the shortage of freight cars was one reason why many purchasers were disappointed. There were also times during the past year when the general conditions of the material markets made it necessary to slow down production until the delayed supplies were received. At the present time there are about 7500 men working at the different plants of the company and from seventy to eighty cars are completed daily.

Knowles Is Saxon Chief Engineer

DETROIT, MICH., Jan. 11—*Special Telegram*—William H. Knowles, for the past year assistant engineer of the Saxon Motor Car Co., has been appointed chief engineer of the company to succeed R. E. Cole, resigned. Previous to his connection with Saxon, Knowles was for two years in the engineering department of the Timken company and later assistant to the chief engineer. He has been associated with the industry for about ten years, serving chiefly with the Warren and Corbin companies. He takes up his new duties at once.

Explains Proposed Gov't Tax on Cars

Sec. McAdoo States That Car Is Taxed But Once and at Factory Only

WASHINGTON, D. C., Jan. 11—Secretary of the Treasury McAdoo has issued the following statement: "The suggestion that tax on the horsepower of automobiles and other internal combustion engines might be considered by Congress, seems to be misunderstood in many parts of the country. A circular just issued by the California State Automobile Assn. and signed D. E. Watkins, secretary, illustrates this. The circular says that a Federal tax of 50 cents per horsepower on motor cars and 1 cent per gallon on gasoline 'Means to you each year nearly twice as much tax as you now pay. We now have men at Washington fighting this bill and are badly in need of financial support. Will you not join this club and help us defeat this unjust measure? If you do not feel that you can contribute $8 for a membership, then send us $1 or whatever amount you will. Now is when we need your support, so please give us an early response.'

Car Taxed at Factory Only

"The suggested tax on the horsepower of motor cars refers entirely to a tax on the automobile before it leaves the factory, to be paid by the manufacturer and paid once only, to the Federal Government; for instance, an automobile with a 20-hp. engine would be taxed $10 in the hands of the manufacturer. No yearly taxation of automobiles and motor trucks similar to the license taxes of States and municipalities is contemplated nor has it at any time been suggested that a Federal tax be imposed on automobiles already in use by private owners."

Vollbrecht Resigns as King V.-P.

DETROIT, MICH., Jan. 7—F. A. Vollbrecht, vice-president and general manager of the King Motor Car Co., Detroit, has resigned and has left the automobile field to engage in manufacturing in Detroit. Theodore E. A. Barthel has succeeded him. Mr. Barthel has been connected with the automobile field since 1902, when he joined the Olds Motor Works. Since then he has seen service with several of the large automobile concerns in the capacity of financial adviser.

Moreland Truck Prices Increased 5%

LOS ANGELES, CAL., Jan. 7—The Moreland Distillate Motor Truck Co., this city, has raised the prices on its trucks 5 per cent. This raise has been made on all models and will take effect immediately.

F. T. C. Concentrates on Gasoline

Commission Will Handle Exclusively Investigations of Reasons for Its High Price

WASHINGTON, D. C., Jan. 8—The latest development in the gasoline situation is the announcement by the Federal Trade Commission that it will handle exclusively investigations to determine the reasons for the high cost of gasoline. Several investigations now are being conducted by the commission to gather data which will enable it to tell whether the present high prices are reasonable.

In addition the commission is attempting to handle a number of complaints from all parts of the country charging discrimination in the price of gasoline. These matters are being handled directly by Commissioner Harris. The first complaints and the greater number of them came from the South and before Congress convened Commissioner Harris and a corps of assistants had gone to the southern States to make on investigation of the violations of the so-called Clayton act, which is the statute relating to price discrimination.

May Give Hearings

This side of the gasoline price probleb is considered by the commission to be a comparatively simple one compared with the investigations to determine whether the price charged is reasonable. Whether the commission will give hearings on the price discrimination phase of the problem has not yet been determined, but it seems probable that it will.

The only matter which the commission needs to help it in reaching a decision is data on refining and marketing costs. Many questions enter into the latter problem, including the determination as to whether more crude oil is being produced now than last year or in previous years; whether the oil is as productive of gasoline as oil taken in former years, etc. Labor costs, as well as depreciation of machinery used in the refining, also must be considered.

Replying to the Steenerson resolution calling upon the Department of Justice for information as to any action on the high price of gasoline, Attorney-General Gregory has sent the following communication to Congressman Webb, chairman of the house judiciary committee:

No prosecutions have been instituted by the government based on the increase of petroleum and its products, for the reason that no evidence has been developed as yet which would justify a charge that the increase is due to any action in violation of federal law. It is the duty of the United States district attorneys and investigators throughout the country to scrutinize closely all increases in the prices of stable commodities and to report promptly any evidence tending to show that such increases were brought about by agreement or combination. This duty has been particularly impressed upon them since the beginning of the European war, which has made it easier to find pretexts for increasing prices.

Opposes Steenerson Inquiry Resolution

WASHINGTON, D. C., Jan. 11—*Special Telegram*—Representative Carlin presented an adverse report from the House judiciary committee on the Steenerson resolution for an inquiry into the rising cost of gasoline on the ground that the attorney-general has answered question fully as stated above.

N. Y. Bankers Dine Willys

NEW YORK CITY, Jan. 11—A dinner was given last night at Sherry's in honor of John N. Willys, president of the Willys-Overland Co., by Elisha Walker, of William Salomon & Co., this city.

The occasion was unique, in that never before has such a gathering met to do honor to a leader of the automobile industry. It shows the importance of the place in the industrial world occupied by J. N. Willys in the opinion of prominent men of finance.

Among the sixty-three guests were: Frank A. Vanderlip, president the National City Bank and a director of the S. K. F. Ball Bearing Co.; E. H. Broadwell, vice-president of the Fisk Rubber Co.; Rathbone Fuller, L. G. Kaufman, president of the Chatham and Phenix National Bank, this city, and chairman of the finance committee of the General Motors Co.; A. P. Sloan, vice-president of the Hyatt Roller Bearing Co., Harrison, N. J.; Harry G. Fisk; H. T. Dunn, president of the Fisk Rubber Co.; Clarence A. Earl, vice-president and a director of the Willys-Overland Co.

Non-Motor-Stop Maxwell Ends Run—Covered 22,022.3 Miles

LOS ANGELES, CAL., Jan. 10—After running continuously for nearly forty-four days, and establishing a record of 22,022.3 miles, the engine of the non-motor-stop Maxwell has been officially stopped by Mayor Sebastian. It was immediately re-started and the car left for a tour through southern California and Arizona. The Maxwell's record replaces a former mark of 12,404.9 miles. The last day's run was made the longest and fastest of all, the car covering 562.5 miles in the twenty-four hours. The entire test was held under the sanction and observation of the contest board of the A. A. A.

Four Companies Raise Tire Prices

Empire, Falls, Globe and Pennsylvania Increase Rates 10 to 25 Per Cent

NEW YORK CITY, Jan. 12—Four more tire companies have raised their prices, the Empire list going up 15 per cent, the Falls 10 per cent, Globe approximately 25 per cent and Pennsylvania about 20 per cent. Kelly-Springfield announced an increase of 7½ to 26 per cent on its former list last week as reported in THE AUTOMOBILE for Jan. 6.

In every instance the reasons given for the higher prices are the scarcity and high market prices for the ingredients used in tire manufacture, crude rubber having risen from 57 cents a pound in September and October to 95 cents to-day. Similar high rates are found in Egyptian and Sea Island cotton and in zinc and sulphur. The great trouble seems to be that the manufacturers are not getting deliveries on materials, many of them being unable to procure the latter at contract prices, the shippers complaining that they are unable to get vessels to transport them.

The Globe company has not definitely decided what increase in its prices will be necessary but, like the other manufacturers, is endeavoring to keep the increase as low as possible.

Some of the new prices on Empire, Falls, and Pennsylvania tires are as follows:

Size	New	Old
EMPIRE		
30 x 3	$11.40	$9.90
34 x 4	24.05	20.90
34 x 4½	32.95	28.65
36 x 4½	34.65	30.15
FALLS		
28 x 3	15.50	14.50
34 x 4	32.75	30.50
37 x 5, non-skid	64.75	58.75
PENNSYLVANIA (All non-skid)		
28 x 3	15.65	12.65
30 x 3	16.60	13.00
30 x 3½	21.05	15.85
37 x 5	58.30	46.85

Culbertson Sails for London

WICHITA FALLS, TEX., Jan. 6—J. G. Culbertson, treasurer and general manager of the Wichita Falls Motor Co., Wichita Falls, Tex., left New York, Dec. 31, on the steamship New York for London, accompanied by Frank Kell, vice-president of the firm. They will return sometime in February.

Price with Rubber Products Co.

BARBERTON, OHIO, Jan. 10—H. A. Price, formerly with the B. F. Goodrich Co., and the Kelly-Springfield Tire Co. has been appointed sales manager of the tire division of the Rubber Products Co., this city.

Two Shows for Chicago

The Automobile Salon and National Show to Be Held Same Week

CHICAGO, ILL., Jan. 10—Chicago will have two shows during the week of Jan. 22 to 29, just as New York had two shows last week. In addition to the show of the National Automobile Chamber of Commerce at the Coliseum and First Regiment armory, there will be a salon held in the Auditorium Hotel, at which the following makes of cars will be exhibited: White, Simplex-Crane, Rolls-Royce, Lancia, Brewster and one or two others. These are practically the same makes that have been exhibited during the past week at Hotel Astor in New York under the name of the Automobile Salon, which has succeeded the Importers' Salon, the latter having been held in the same place in New York for many years. The show this year has had many more American cars than foreign makes, in fact, only five different makes of foreign cars were exhibited last week, whereas there were American cars of the following makes on exhibit: White, Packard, Locomobile, Cadillac, F. R. P., Simplex, Crane, Singer, Daniels, Owen Magnetic and Brewster. White exhibited at the salon, because it withdrew from the N. A. C. C. show because of differing with the association on the matter of drawing space. Many of the other exhibits of American cars, such as Locomobile, Cadillac, Owen Magnetic and Packard were made by the body builders and not by the companies themselves.

European War Beneficial to Italian Makers

TURIN, ITALY, Jan. 7—The effect of the European war on automobile and truck manufacture in this country has been beneficial. The industry, centered in Turin, profited by the increased demand for military trucks, both at home and abroad, and all of the plants were compelled to employ extra workmen and to introduce night shifts. This stimulation to an industry which had begun the year rather unfavorably offset to a large degree the depressing effects of the crisis in other local industries. The decree of Aug. 1 prohibited the exportation of automobiles, but exceptions were granted with a certain liberality in the case of medium weight and heavy trucks, so that the total value of the exports of motor vehicles was larger than in the preceding year, there being $7,849,695 in motor vehicles in 1914 compared with $6,596,921 in 1913.

The largest company, the Fiat, turned out 4800 automobiles in 1914, which is 1500 more than in the preceding year.

The future of this industry is promising, as the trucks lost in the war will have to be replaced and the local factories will be occupied for some time to come in supplying the demand. The exchange quotations of the shares of the Turin companies are given in dollars in the following table:

Companies	Nominal Value	Market Value, December, 1913	Market Value, December, 1914
Fiat	$10.30	$24.32	$24.32
Itala	4.82	9.84	7.72
Spa	4.82	5.21	5.50
Scat	4.82	4.15	4.82
Diatto Clement	4.82	2.30	2.70
Peugeot	4.32	.35	.....

The automobile coach-building industry, on the contrary, has been seriously injured by the war which has almost eliminated the demand for passenger cars and caused the exportation of this class of vehicle to cease. The cost of all supplies for this branch has greatly increased, particularly hides, varnishes, and cloths, as well as other accessories, which were previously supplied by England, Germany and France.

U. S. Rubber Introduces Usco Tread and Royal Cord Tires

NEW YORK CITY, Jan. 10—Rounding out the line of the United States Tire Co. so that it comprises a tire for practically every need, the Usco tread and the Royal Cord tires have been put on the market, the former selling at a very slight advance on the plain tread prices while the latter lists at practically the same price as any other first-class cord construction.

The Usco tire uses a tread pattern made up of two rows of the letter U, one on each side of a plain strip in the center of the tread, the letters in each row being staggered in relation to those of the others. Another advantage of the Usco is said to be the special strength secured by a practically perfect union between the fabric and the rubber, the plies of the fabric being unified by rubber joined to the fabric.

The Nobby tread and Chain tread are continued by the United States company, and commercial vehicles are provided for by the new Pressed-On truck tire recently announced.

Scripps-Booth Capital Stock Increased to $350,000

DETROIT, MICH., Jan. 7—The Scripps-Booth Co. has increased its capital stock from $150,000 to $350,000, for the purpose of enlarging its plant and increasing its manufacturing facilities. The company has elected Clarence H. Booth vice-president and managing director.

250,000 See New York Show

Largest Attendance of Any Exhibition Held in That City—Sales Big

NEW YORK CITY, Jan. 10—The sixteenth annual automobile show held in held in New York City closed Saturday night after a week of record-breaking attendance and sales, approximately 250,000 persons, or 33 1-3 per cent more than last year, inspecting the 326 cars and chassis as well as the 290 accessory exhibits on display in the Grand Central Palace. This is the largest attendance recorded for any automobile show, horse show or other great exhibition ever held in this city. In fact, during the entire week, hotels were over-crowded and theaters overwhelmed with demands for tickets. Never have the huge hostelries of the metropolis experienced such a rush of business with the exception of the week of the Hudson-Fulton celebration. And the tremendous crowd which came to see the show, to sign new contracts, buy cars and negotiate for replenishment of accessory stocks contained 40 per cent more dealers in cars than were in evidence at the 1915 show.

The exhibitors themselves were delighted with the sales made, new agents obtained, and general business done and, practically to a man, declared the week to have been one of unprecedented success as compared with the shows of previous years.

Business-Like Atmosphere

The atmosphere of the show this year was more business-like than has ever been the case. More people seemed to come to the show with the intention of buying a car than ever before and the questions of visitors at the various booths were in every case evidence of the greatly increased familiarity of the general public with the essentials of construction and the performance to be expected from the cars of to-day. These questions reveal marked attention to details which in former years were passed over without comment. The dealers state that the great improvement in business confidence over the corresponding period a year ago was reflected in the attitude of the show visitors, who seemed to have more ready money and to be more inclined to spend it than at that time. More retail sales are reported than ever before, practically every exhibitor having sold a number of cars while some of the more popular low-priced makes reported many sales each day.

From the dealers' standpoint the show has netted more live prospects for immediate and spring delivery of cars than any previous exhibition, in fact, some exhibitors sold more cars last week than in an entire month of the past year. In addition many new contracts were signed and much new territory covered for 1916. Practically all the dealers predict a big shortage of cars for next summer's selling season. The attendance of dealers at the show was much better than expected, men coming from as far south as Florida and as far west as Omaha, St. Louis and Kansas City with a few from the coast. As to the individual exhibitors' opinions of the show, these may be realized from the statement that the sales made vary from 40 to 600 per cent in excess of those at any previous show.

Accessory Exhibitors

In the accessory field it is the same story over again. Though here the sales made during the week were in most cases comparatively small, the general interest shown the new contracts secured and territory distributed served to make the net business gain far above that attained at last year's display.

Laurel Four for $750—Six to Come Later

RICHMOND, IND., Jan. 7—The Laurel Motor Car Co., this city, announces a new four-cylinder car to sell at $750, and soon will have ready a six that will sell somewhat under the $1,000 mark. Specifications of the four include a block motor with cylinders measuring 3 by 4¼ in., rated at 22.5 hp. Under brake test the motor is said to give 31.9 hp. at 2,000 r.p.m. The bearings are unusually large, the crankshaft front bearing being 1½ by 3⅞ in., center, 1⅝ by 2¼ and rear, 1⅝ by 4 in. The oiling system is a combination force-feed and splash, with revolving sight feed on dash, to which the oil is forced by a plunger pump. This sight feed is provided with an oil line leading the oil back to the three main bearings of the motor and then runs into the stamped steel oil tray. Cooling is by thermo-syphon.

The motor has a detachable cylinder head, and the clutch is a single disk in oil. Three speeds forward are offered, drive is left and control levers in the center.

Body design is conventional, the rear seat being 48 in. wide and the upholstering is heavy and of good material. Among the equipment is found one-person top, demountable rims, speedometer, electric starting and lighting, electric horn, etc.

Linerd Resigns from Ajax-Grieb

NEW YORK CITY, Jan. 11—J. B. Linerd, sales manager of the Ajax-Grieb Rubber Co., this city, has resigned to become president and general manager of the Bourne Chemical Corp., also of this city. No successor has been appointed.

550 Attend S. A. E. Banquet

Engineers Hear Officials of Army, Navy and Automobile Industry on Preparedness

NEW YORK CITY, Jan. 7—One of the most successful banquets ever held by the Society of Automobile Engineers was given last night at the Hotel Plaza, approximately 550 being present. The speakers included Secretary of Navy Josephus Daniels, Major General Wood, U. S. A. Commander of the Department of the East, and Alfred Reeves, General Manager of the National Automobile Chamber of Commerce. The dinner was presided over by William VanDervoort, president of the society.

Preparedness the Keynote

Preparedness was the keynote of the addresses given at the close of the banquet. President VanDervoort first addressed the members, extending a welcome and reviewing the accomplishment of the society. He pointed out the peculiar fitness of the Society of Automobile Engineers to be an efficient aid to the Government in time of war and peace and assured the Government that the society is willing to not only extend words expressing intentions, but would also be ready to take officers of the Navy and Army into the plants of the manufacturers for the purpose of instructing them in the intricacies and economics of manufacture.

General Wood delivered a brief speech, in which he brought out the necessity of the organization of industries to support the fighting arm of the service. He compared the situation to that of a heavy sword in which the keen edge is the first line of fighting proof, but in which the mass of metal which enables the edge to acquire the desired strength and stiffness is the industrial resources of the country. The better organized this industrial group is, the more efficiently can the keen cutting edge be kept in its proper condition.

Need of Truck Standards

An important point brought out by General Wood in his address is the need of standardization of the motor truck. He stated that the Army did not desire a miscellaneous mass of different sizes and varieties of vehicles to aid in transportation problems, but rather a standard form of vehicle upon which replacements would be easily made. He also said that he hoped an Army consulting board similar to that recently created for the Navy would soon be formed.

Secretary Daniels stated that the Navy department would assuredly appreciate the opportunity of sending officers to the automobile factories for the purpose of securing technical information, and it is probable that, beginning with the coming spring, squads of officers will be sent to the automobile factories. The need for a good aeroplane motor was mentioned by Secretary Daniels, who pointed out that the automobile engineers would be the logical men to develop it.

Considerable time was spent by Secretary Daniels in pointing out the necessity for an adequate Navy in this country, and the evident indorsement of the members of the S. A. E. present was shown by the enthusiastic reception of Secretary Daniels' expression of views.

The Motorists' Part

Alfred Reeves, general manager of the N. A. C. C., spoke of what the automobilist should do in time of war. He pointed out to General Wood that the 240,000 automobiles in the State of New York alone should move 1,000,000 men over the roads at an average speed of 30 m.p.h. There were about 550 at the banquet, and among the prominent guests were William McClellan, vice-president of the American Institute of Electrical Engineers; C. C. Hanch, director of the National Automobile Chamber of Commerce; William L. Saunders, president of the American Institute of Mining Engineers; Dr. J. S. Jacobus, president of the American Society of Mechanical Engineers; Howard E. Coffin and A. L. Riker, both of the Naval Consulting Board and members of the Society of Automobile Engineers; W. H. VanDervoort, president of the society, and A. J. Hemphill, president of the Automobile Club of America.

M. & A. M. Directors and Officers Re-elected for 1916

NEW YORK CITY, Jan. 6—At the twelfth annual meeting of the Motor and Accessory Manufacturers, held at the Waldorf-Astoria yesterday, the following were re-elected as members of the board of directors: F. Hallett Lovell, Jr.; C. E. Thompson, A. P. Sloan, Jr., and C. E. Whitney. W. M. Sweet continues as manager.

At the meeting of the board of directors held in the association's offices today, the officers whose terms had expired were re-elected to serve for an additional year. They are as follows: President, F. Hallett Lovell, Jr., Lovell-McConnell Mfg. Co., Newark, N. J.; first vice-president, C. W. Stiger, Stromberg Motor Devices Co., Chicago, Ill.; second vice-president, C. E. Thompson, the Steel Products Co., Cleveland, Ohio; third vice-president, T. J. Wetzel, the Dyneto Electric Co., New York City; treasurer, L. M. Wainwright, Diamond Chain & Mfg. Co., Indianapolis, and A. P. Sloan, Jr., Hyatt Roller Bearing Co., Newark, N. J.

National Acme Takes Windsor Machine

$3,500,000 Deal Practically Closed—Details to Be Decided at Jan. 20 Meeting

CLEVELAND, OHIO, Jan. 10—The negotiations by which the National Acme Manufacturing Co. of this city is to acquire the business and plant of the Windsor Machine Co., Windsor, Vt., have been practically closed. The deal involves about $3,500,000. The capital stock of the local company will be increased to take care of this addition, but any further amount will not be decided upon until the annual meeting is held on Jan. 20. The details will then be worked out for the consolidation.

Portage Rubber Profits Increase 46½ Per Cent

BARBERTON, OHIO, Jan. 6—The financial report of the Portage Rubber Co., made public at the annual stockholders' meeting, showed net profits from operation of $129,000 for the year 1915, which is 46½ per cent above those of the previous year. The sales amounted to $1,100,000, an increase of 62½ per cent over 1914. The usual quarterly dividend of 1¾ per cent on the common stock of the company was declared.

Officers elected were: James Christy, president; M. S. Long, vice-president; W. J. Anderson, secretary, and W. W. Wildman, treasurer.

Overland 1915 Earnings Estimated at $10,000,000

TOLEDO, OHIO, Jan. 10—Willys-Overland earnings last year amounted to $10,000,000, according to a circular sent to the holders of the preferred and common stock. This amount is equal to over 9½ times the preferred dividend requirements on the $15,000,000 issue and equal to 45 per cent on the common stock. The average surplus for the 3¼ years ended Sept. 30, was $6,893,622, or six and one-half times the annual dividends on the new $15,000,000 in convertible 7 per cent preferred stock issue.

The proceeds of the new issue will be applied in retiring existing $4,483,700 preferred stock, and to the general funds of the company. The new convertible preferred stock is exchangeable from Jan. 1, 1917, to Jan. 1, 1922, into common stock at 300. In the event that additional common stock is issued as a dividend or at prices less than $300 per share, the conversion price is to be proportionately reduced. The company is to set aside, on or before July 1, each year, commencing with 1917, a sum equal to 3 per cent of the par value of the preferred stock as a sinking fund.

Markets Easier

NEW YORK CITY, Jan. 12—Market prices last week were easier. Prices on those commodities which have seen violent rises during the past few weeks, either remained constant or were lower. Steel prices were unchanged, though the demand by the manufacturers was as urgent as it has been during last month. Lead and copper, however, continue to rise, the former closing yesterday at $5.90 per 100 lb. and the latter at 23½ cents a pound. Tin, on the contrary, dropped yesterday to $41.50 per 100 lb. This metal has always been subject to violent changes, however, and so the latest reduction cannot be taken as a mark of further reductions.

The rubber market was quiet last week and prices were somewhat lower. Para, which earlier in the week reached the $1 mark, declined to 96 cents, yesterday, and Ceylon pale crepe likewise saw a reduction and closed at $1.03. The demand for rubber last week was weak as was that in London.

Gasoline in this city went up another notch in its unprecedented climb toward new high marks, quoting at 22 cents a gallon. The increasing price of gasoline has brought benzol as a substitute into greater prominence. In many parts of the city last week, it was noted that garages displaying on signs the price o gasoline, had posted a roughly painted number—usually 25 cents—over th former price, as if the new price wer merely temporary, and another an higher price might be quoted the nex day. Benzol as a substitute for gasoline has been the subject of the evenin at a number of meetings held in thi city lately, especially at the Chemists Club, recently, where it was stated tha with the present immense production o benzol the cost has been reduced unti now it is believed that it can be manufactured and sold at a profit at the pro portionate price of gasoline, and that thi will be done after the war is over. Pro portionate price means that, when it i considered that benzol has a motiv power about 25 per cent greater tha gasoline, it would consequently have 2 per cent advantage at the same price.

Aluminum Shortage Grows

The scarcity of materials has hit man of the manufacturers. Especially is thi true in aluminum. Manufacturers of mo tors and parts in and around Milwauke it is said, are apprehensive of a seriou shortage of that metal and report tha already there is a necessity for returnin to the use of cast iron parts because o the soaring prices and the added difficult of getting a sufficient supply. A shor age of high speed steels is also reporte and the restricted supply of tool steel coupled with greatly increased price may prove a hardship during the co ing year.

Thomas Receivers File Report

BUFFALO, N. Y., Jan. 8—The receive of the E. R. Thomas Motor Car Co., thi city, have filed their report in which the state that the total receipts of the r ceivership have been $512,025.23; th claims filed aggregate slightly more tha $1,000,000, on which there have been pai dividends aggregating 30 per cen There is now cash in the hands of th receivers amounting to $39,938.88.

Chicago Gasoline Prices Reduced

CHICAGO, ILL., Jan. 7—Gasoline pric in this city have dropped to 16½ cent nearly 2 cents. The Standard Oil C it is said, is responsible for the lo price.

Reports from the Oklahoma and Tex oil fields state that there is an oil fami and that the oil wells in those two Stat have slumped in production from 35 to per cent. Gasoline prices, as a result, is predicted, will reach in the near f ture 40 cents a gallon and oil by-produc will be 35 to 40 per cent higher than any time in the history of the Unit States.

Advances of 1 cent a gallon in whol sale gasoline prices were put into effe in the entire eastern territory last wee

following the advances on the Pacific Coast.

The New York City price to garages is now 22 cents a gallon, which compares with a price of 12 cents on March 31 last. The same schedule is effective for Standard Oil of New York territory in Long Island and Connecticut. In other New England States the price is 1 cent higher at 23 cents.

The schedule for New Jersey is 21 cents; for Ohio 19 to 21.

Bowen Resigns from Locomobile—To Build Automobiles

New York City, Jan. 12—Frank H. Bowen has handed in his resignation as sales manager of the local Locomobile branch. He is at present engaged in the promotion of a scheme to build automobiles.

Gier Pressed Steel Co. Now

Lansing, Mich., Jan. 7—The name of the Gier & Dail Mfg. Co., has been changed to that of Gier Pressed Steel Co. The concern started in business in July, 1909, with a capital stock of $35,000, making among other things metal stampings and steel products.

Regular Dividends Declared

United States Rubber Co.; quarterly on first preferred of 2 per cent and on second preferred of 1½ per cent, payable without closing of transfer books, Jan. 31.

Ajax Rubber Co.; quarterly of $1.25 per share; payable March 15 to stock of record Feb. 28.

Security Prices Lower

General Motors Drops 35 Points —Studebaker Drops 6— Maxwell Lower

New York City, Jan. 12—Automobile and accessory issues last week suffered a setback in prices, due to a downward movement in quotations on the Stock Exchange and an inactive market. The decline last week of those stocks which have seen new high marks was a keen disappointment to those who have money invested in those issues. General Motors common, especially, has declined during the past two weeks. On Saturday it quoted at 455, just 83 points under its high mark on Dec. 13. Notwithstanding the adoption of a 20 per cent dividend rate and the declaration of a 5 per cent dividend for the last quarter of 1915, in addition to 5 per cent for the current quarter, the stock closed 35 points under last week's quotation. The decline depressed other stocks.

Willys-Overland common dropped 6 points to 226 as did that of Studebaker, which closed at 159. Maxwell common, first preferred and second preferred, declined 3½, 2 and 1 points, respectively. Chalmers also went down to 125 with a 5-point loss. Chevrolet closed at 126, just 4 points lower than last week's quotation. Reo Motor Car dropped 2 points to 30 as did White, which closed at 49½.

Firestone common, Peerless, J. I. Case and Goodrich preferred, were the only stocks to make any appreciable gains during the week. Firestone went up 10 points to 720; Case rose to 85; and Goodrich went up 1 point to 113. Ajax dropped 1½ points. It is claimed that current earnings of the Ajax company are at the rate of more than 25 per cent per annum on the company's $3,000,000 outstanding capital stock.

Detroit issues also declined last week, General Motors, Studebaker, and Maxwell showing the largest drops. General Motors common went down to 445 with a 12½-point loss; Studebaker quoted 7 points under last week's quotation and closed at 159½; and Maxwell common was 5¼ points lower, quoting at 69½.

Hercules Is Now Dixie Motor Car Co.

Louisville, Ky., Jan. 7—Complying with the will of a majority of the stockholders of the Kentucky Wagon Works, ratified at a meeting several days ago, to conduct an automobile manufacturing plant in connection with the regular business of the concern, officers yesterday filed articles of incorporation of the Dixie Motor Car Co., the capital stock of which is fixed at $150,000, divided into 1500 shares of a par value of $100, two-thirds of which is common stock fully subscribed, and one-third preferred stock.

The articles are in the nature of an amendment to the Hercules Sales Co., in which the name is changed to the Dixie Motor Car Co., and the amount of capital stock increased from $100,000 to $150,000, the owners of the capital stock of the old concern becoming the owners of the common stock of the new. Incorporators of the new concern are P. S. Tuley, C. D. Kelso, W. E. Massey, A. H. Ross, J. R. Duffin and R. V. Board.

A. B. C. Ford System Is Effective

Two Unit Disposed in Novel Manner—Motor of High Cranking Power

NEW YORK CITY, Jan. 10—The outstanding novelty in the A. B. C. electrical starting and lighting system for Fords to be made by the A. B. C. Starter Co., Detroit, Mich., as announced last week, is the location of the cranking motor. This is usually the most troublesome part of a Ford system, as if it operates through a chain the latter needs some attention, and if it connects to the crankshaft it must stand in front of the radiator.

The A. B. C. motor lies alongside the crankcase near the right front where it is entirely out of the way. Integral with its casing is an inclosed gear reduction looking something like the timing gears of a small gasoline motor and this case is of course quite narrow. The small pinion of the gear train is on the starting motor shaft and the large gear is of such a size that it comes in line with the crankshaft, the inclosing case bolting to the front frame member so that the gears come beneath the radiator where their case is concealed by the license tag.

On the spindle of the large gear there is a Bendix pinion, but instead of being a toothed wheel the pinion part is formed just like the starting jaw of a hand crank. Thus, when current is switched into the motor, the gears begin to turn, the Bendix "pinion" jumps forward and the jaw takes hold of the Ford crankshaft just exactly as the old hand crank used to do. The reducing gear gives lots of power and the control is a switch.

For the generator drive a belt is used after the manner which has proved so successful on the Maxwell. There is a pulley on the crankshaft and the belt passes round the fan and the generator, giving an easily tensioned triangular drive. The generator locates on the front left side of the engine, fairly high.

For controlling the output of the generator a Ward-Leonard controller is employed. The system as supplied includes everything, a battery which fits on the left running board, wiring for headlights and tail lamp, dimmer switches, etc.

17,300 Paige Sixes for 1916

DETROIT, MICH., Jan. 10—At the annual meeting of the stockholders of the Paige-Detroit Motor Car Co., it was announced that during the fiscal year 1915, which ended Aug. 31, nearly 8000 Paige cars were made and sold. For the 1916 fiscal year the production schedule calls for 17,300 cars. The profits of the company during the past fiscal year were nearly 430 per cent greater than in 1914, and the earnings 130 per cent on the capital stock. The production schedule is being maintained at the rate of 150 cars a day, hut provisions have been made in all departments to enable the output to be 300 cars a day on a ten-hour working basis. Conditions throughout the country as reported by Paige dealers and distributors are the best the company ever had. The demand is steady and on an increase in every section of the country.

Goode Leaves Paris Branch of Packard Motor Car Co.

PARIS, Dec. 24—R. N. Goode, manager of the Paris branch of the Packard Motor Car Co., severs his connection with that firm on Jan. 1. No arrangements have been made for a successor, and it is understood that the Paris office will be closed, at any rate temporarily. This will not interfere with the Packard truck business in France, which is handled direct between the factory and the French army. Mr. Goode, who has had charge of Packard interests in Paris for the last five years, and is well known to American visitors to Europe, has linked up with Gaston, Williams and Wigmore, Ltd., and in conjunction with his brother, Keith Goode, will have charge of the French and Italian markets for that company.

Take American Truck Agencies

F. Charron, one of the founders of the Charron and the C. G. V. automobile companies, now president of the Alda Automobile Co., has taken up the agency in France for the Federal truck. Charron's factory at Courbevoie, near Paris, is almost completely occupied on shells, only a few touring cars being built; thus the truck agency is a side line.

Another French automobile manufacturer is about to take up the agency for the U. S. truck. The Jeffery company has opened a spare parts depot at Neuilly, in the suburbs of Paris, to give service in connection with its Quads.

At the present time there is a demand in France for trucks for civilian uses which local manufacturers are unable to meet, owing to the demands of the war department. Practically all private trucks were requisitioned by the army months ago, and users, after being content with temporary measures for a time, are now looking around for permanent relief.

Fire in Chevrolet's Tarrytown Plant

TARRYTOWN, N. Y., Jan. 7—Fire due to spontaneous combustion in a testing shed of the Chevrolet Motor Co., at Kingston Point, to-day did damage estimated at $50,000. The building, a one-story brick structure, 100 by 65 ft., was gutted.

Omaha Sales Show 100% Gain

Car and Accessory Dealers Optimistic—Many Enlarge Distributing Quarters

OMAHA, NEB., Jan. 7—An increase of 100 per cent in the automobile business for the past year in Omaha—acknowledged third largest automobile distributing point in the United States, by the way—is taken by local dealers and distributors as a reasonable ground upon which to base an estimate of the progress of the industry in the entire country.

The steady enlargement of quarters, the removal in many instances of dealers and distributors to new locations with immensely increased stocks and facilities, with the building of several new houses during the year, are all taken as measures of prosperity.

Bour-Davis Co. Formed

DETROIT, MICH., Jan. 10—The Bour-Davis Motor Car Co. is a new Michigan corporation with a capital stock of $500,000, organized by Chicago men to manufacture a low-priced car here. The incorporators are prominent business men of the Windy City, but this seems to be their first venture in the automobile industry. They are Robert C. Davis, engineer for the Chicago, Duluth, Lake Superior Steamship Co.; Charles J. Bour, well-known in advertising circles in Chicago; and E. C. Noe, general manager of the Chicago Elevated railway system.

To Fight Bill for Yearly Registration in D. C.

WASHINGTON, D. C., Jan. 8—A bill introduced in the House by Congressman Cary, of Wisconsin, provides that on and after July 1, 1916, it will be unlawful for any person to operate any motor vehicle within the District of Columbia without having first obtained from the automobile board a certificate of registration and number plates. The color of the plates is to be changed each year and the horsepower of all engines or motors is to be computed.

The license numbers will expire at midnight on June 30 of each year. The fees provided by the bill are as follows: For each motor vehicle with a rating of 10 hp., $5 per year; more than 10 and less than 20 hp., $10; more than 20 and less than 30 hp., $15; more than 30 and less than 40 hp., $20; 40 hp. or more, $25. It is provided that the automobile board may issue to a dealer or manufacturer of motor cars a certificate of registration and number plates not to exceed four sets, upon payment of $6 for each set.

All cars used by the United States Government and the District of Columbia are to be provided with license plates free of charge. All members of Congress are to be exempt from the provisions of the proposed law, providing they have complied with the laws in their respective States. All privileges shall be accorded to the residents of other States as are accorded by law to residents of the District of Columbia.

It is expected that motorists will put up a strong fight against the Cary bill.

Dodge Bros. Get Injunction on Use of Name

DETROIT, MICH., Jan. 7—To-day the Wayne County Circuit Court issued a restraining order in favor of Dodge Bros. against the Dodge Motor Car Co., whereby the latter cannot use the name Dodge in connection with the manufacturing of its cars.

Dodge Bros. filed suit against the Dodge Motor Car Co. in August, 1914, because this concern which had started in business in July of that year, was using the name Dodge on its cars. The company was promoted by Alvan M. Dodge, who was formerly with the Wahl Motor Car Co. Dodge Bros. claimed that the new company was trying to profit by the name Dodge, which had then been well known for a period of twelve years.

While the Dodge Motor Car Co. made a few cars, it ceased to manufacture a few months after it had started in business.

Marvin Batavia Rubber Treasurer

NEW YORK CITY, Jan. 10—New York capital will aid the Batavia Rubber Co., with factories at Batavia, N. Y., and sales and financial offices recently established in this city, in extending and developing its business, Charles F. Marvin, formerly of Blake Bros. & Co., having become treasurer and a member of the board of directors, and George W. Hodges, of Remick, Hodges & Co., having also been added to the board of directors. Both will henceforth take an active interest in the company. They succeed O. C. Carpenter and Horace F. DeCamp of this city. There is no other change in the personnel of the company.

H. A. L. Leases Royal Plant

CLEVELAND, OHIO, Jan. 7—The Harry A. Lozier Co., this city, has leased for a short term the Royal Motor Car Co. plant along the Lake Shore tracks west of Gordon park. Within two weeks the manufacture of the H. A. L. twelve will have begun. The first car manufactured was on exhibition last week at the New York City automobile show. It is stated that a permanent site for the plant is now being negotiated for.

15,000 Overlands for Kansas City

Big Allotment To Be Handled in Enlarged Territory by New Branch

KANSAS CITY, MO., Jan. 7—The Willys-Overland Co., Toledo, Ohio, has taken over the local agency as a factory branch and installed S. W. Ramsey, who for the past two years has had charge of the sales department here, as branch manager. The territory to be served from Kansas City has been enlarged by the addition of the States of Arkansas, Oklahoma, New Mexico and parts of Nebraska and Oklahoma to Kansas and the portion of Missouri that formerly was handled from here.

The establishment of the factory branch here will mean an actual investment by the Willys-Overland Company of approximately $1,000,000 in real estate and buildings. Recently the building now occupied by the agency at 2110 Grand Avenue and 95 ft. of vacant property north of it was purchased for $250,000. As soon as possible work will start on the construction of a six-story building to occupy the entire 135-ft. frontage on Grand Avenue.

In addition, it has been given out that a 5-acre tract on the Belt Line will be acquired and a building with approximately 500,000 sq. ft. of floorspace will be erected as storage quarters. The present structure on Grand Avenue and the new building to be erected there will be used only as a show room and shop and not for storage purposes. The Belt Line property will be necessary for the storage uses.

The year just ended found the Kansas City agency distributing approximately 5000 cars in Kansas and western Missouri. With the addition of three whole States and parts of two others it is believed at least three times that number will be handled from here and the factory has allotted 15,000 cars to Kansas City as its 1916 quota.

80 Per cent of Packard Output Sold—Factory Works Day and Night

DETROIT, MICH., Jan. 10—"Our manufacturing schedule calls for 7750 twin-sixes for this fiscal year," said Sales Manager H. H. Hills, of the Packard Motor Car Co., and of this number 80 per cent have been contracted for. At the rate orders are coming in from our dealers, distributors and branches, we could dispose of an additional 5000 cars. In addition to those 7750 cars we will build a very large number of trucks, but here again conditions, which we cannot overcome now, will not make it possible to produce the number that could be sold. We are doing everything possible to increase our production. We are adding to our working force, we are making extentions to the plant, more equipment and other necessities to increase production are being added, and yet we cannot keep pace with the demand. Many departments are being worked with day and night shifts and the truck department especially has orders now which will keep it busy day and night for several months."

Austin-Cadillac Suit Ends

DETROIT, MICH., Jan. 4—Judge C. W. Sessions of the United States district court in Grand Rapids, Mich., to-day signed the final decree in the Austin-Cadillac two-speed axle case.

It was on Jan. 8, 1915, that the judge rendered a decision in favor of Walter S. Austin, of the Austin Automobile Co., Grand Rapids, granting the latter's demand for an injunction and damages against the Cadillac Motor Car Co., ordering an accounting so that the amount of damages could be fixed.

The parties since then had agreed upon a form of decree, and it is this decree which now has been confirmed by the judge and signed by him and thus brings the case to an end.

Suit was started by Mr. Austin in July, 1914. He claimed that the Cadillac company infringed his two-speed axle patent, No. 1,091,618, which had been issued to him in March, 1914.

Hyatt Employees Form Class in Iron and Steel Metallography

HARRISON, N. J., Jan. 11—Employees in the physical testing laboratory of the Hyatt Roller Bearing Co. factories have organized a class in the metallography of iron and steel. The course consists of correspondence lessons prepared by Professor Sanveur of Harvard and is supplemented by letters and practical examples taken from the regular shop work. The course consists of two lessons a week and will continue over a period of six months.

Tuition is charged for the course but any employee remaining with the company two years will have his tuition refunded to him. The Hyatt company has permitted the use of its metallographic apparatus for the carrying on of the work and prizes will be offered for the greatest progress.

Missouri Dealers Want Lower Fees

ST. LOUIS, MO., Jan. 8—A strong movement for the reduction in the price of State automobile licenses has appeared among automobile dealers in St. Louis. The present system, they say, has had a deterrent effect on automobile sales during the closing months of the closing year.

Every automobile owner in Missouri must take out a license each year, the cost of which varies from $2 to $12, according to the horsepower of his car. The cost of a license is the same no matter when taken out, so that short-lived license is just as expensive as one which has a full year to run.

Plans are being made by automobile dealers to influence the next General Assembly to establish a license graded according to the time it covers.

"I know five automobile prospects who have put off the purchase of a car because they were unwilling to pay a full year's license for a few months' use of their car," said Frank R. Tate, president of the Tate-Gillham Motor Car Co.

Form Wolverine Tractor Co.

DETROIT, MICH., Jan. 10—The Wolverine Detroit Tractor Co., is being formed here to manufacture a motor tractor which is to sell at from $800 to $900. The promoters of the company are W. G. Wagenhals, formerly vice-president of the Wagenhals Motor Co., who is the designer of the tractor, and W. J. McNamara, former mayor of Edmonton, Alberta, Canada, and reputed to be the owner of more than 20,000 acres of farm land in that section of Canada. Temporary offices have been opened at 664 Grand Avenue. The tractor is to appear at the Detroit show, Jan. 15 to 22.

Banner Buggy Co. Reduces Its Capital to $400,000

ST. LOUIS, MO., Jan. 5—Simultaneous with the beginning of operations at the new St. Louis Chevrolet assembling plant the Banner Buggy Co., part of whose plant was converted into an automobile factory, has announced a decrease of its capital stock from $700,000 to $400,000. Russell F. Gardner, president of the buggy company, is also president of the recently incorporated St. Louis Chevrolet Co.

Mr. Gardner has converted a large portion of his buggy factory into an assembling plant and turned out the first St. Louis-made Chevrolet "Four-Ninety" on Jan. 1. The local plant, Mr. Gardner says, is to supply the entire Southwest and Middle West with Chevrolet cars.

King Resigns from Jones

WICHITA, KAN., Jan. 6—W. A. King, general factory manager and consulting engineer of the Jones Motor Car Co., this city, has resigned, his resignation to take effect Feb. 15. He has accepted a position with a new organization now being formed to build cars. He will hold the same position that he is holding at present with the Jones company.

A. A. A. To Pick Master Driver

Contest Board Will Also Select Master Car for 1916 Racing Season

NEW YORK CITY, Jan. 10—The contest board of the American Automobile Association has tentatively decided to select the master driver and master car in the 1916 speedway and road-racing circuit, thus following the example set by *Motor Age* during the past several seasons of selecting the master or winning driver for road racing and also for speedway racing. Plans are yet chaotic, but the suggestion has been made to award the driver so distinguished with a gold medal, carrying his profile on the front and a suitable inscription on the rear, and to further give him $500 in gold. The complete details of the scheme will be worked out in the near future by the contest board.

During the past year *Motor Age* awarded the speedway supremacy to Gilbert Anderson, piloting a Stutz car, and road-racing supremacy to Earl Cooper, also driving a Stutz. The minor speedway circuit was awarded to Edward Rickenbacker in a Maxwell. In making these awards the two invitation 100-mile speedway races won by Resta were not considered because of their invitation nature. It was necessary to establish a major speedway circuit made up of Indianapolis, Chicago, New York and Minneapolis, and a minor circuit of smaller tracks where shorter races for smaller purses were offered.

Miller Is Vice-President of Miller, Hicks & Hewitt

NEW YORK CITY, Jan. 11—Roland Van G. Miller, formerly sales manager of the Hune Carriage Co., Boston, Mass., has been elected vice-president of Miller, Hicks & Hewitt, manufacturers of automobile bodies in this city.

Austin Heads Dry Climate Tire

DENVER, COL., Jan. 7—The Dry Climate Tire Mfg. Co., Denver and Arvada, has elected E. A. Austin, of Boulder, president to succeed C. W. Clark; A. L. Davis, Arvada, director and vice-president, and W. H. Davis, Fort Lupton, secretary. The recently organized firm has a factory at Arvada and sales office in Denver.

Auto Wheel to Add 100 Men

LANSING, MICH., Jan. 5—Within the next two or three weeks additions to the plant of the Auto Wheel Co. will be completed and about 100 more men will be added to the working force, bringing the force up to about 300 men. Business in 1915 was the best the company ever had, and orders now on the books from regular customers will keep the plant busy until August. Recently new housings were erected, and it is said that the company now has about 1,000,000 ft. of lumber stored.

Reo Starts Night Work

LANSING, MICH., Jan. 10—Night work was started at the plant of the Reo Motor Truck Co. a few days ago. A force was put to work in the automatic screw machine department and from now on night shifts will be added in other departments. These night workers work 14 hr. a day during five days. The day workers, who work six days a week, work only 10 hr. a day.

Velie Sales Gain 400 Per cent

MOLINE, ILL., Jan. 10—In spite of having been somewhat held back by the materials situation, the Velie Motor Vehicle Co., this city, states that its car sales for November were 400 per cent greater than a year ago. Further plans for manufacturing expansion are now under way.

South Dakota Fees Now Only $3

PIERRE, S. D., Jan. 7—Several changes are noted in the new automobile tag license law. The fee is $3. Formerly it was $6 per year payable in two bi-yearly installments. A discount of 50 per cent on the license fee for cars operated five years or more has been done away with.

Allen Motor Co. Expands

FOSTORIA, OHIO, Jan. 6—The Allen Motor Co., this city, has increased its capital stock from $100,000 to $1,500,000. Of the new capitalization $500,000 is preferred stock all of which has been taken by Cleveland capitalists. The additional capital will be used in making improvements on the plant.

Limberg Buys Delage Racer

PARIS, Dec. 31—Carl Limberg, who is now in Paris, has closed a deal with the Delage company for the purchase of one of their 1914 Grand Prix racing cars. The car has been purchased conditional to the government permit to export being obtained. It is not believed that there will be any difficulty in getting this permit. The car is one of the sixteen-valve type with positively closed and opened valves. It is Limberg's intention to run it in the Indianapolis and other American races next season.

10,000 Kings for 1916

NEW YORK CITY, Jan. 7—The King Motor Car Co., Detroit, will build 10,000 cars this year, according to plans announced this week.

Corona Wants Grand Prix

International or Corona Grand Prix May Be Held March 17

LOS ANGELES, CAL., Jan. 5—Corona may hold a race in 1916. There remains but 2 miles of the highway from Los Angeles to Corona to be completed and permission has already been granted by the city trustees for a race on the course.

There is but one condition under which the race is to be run. There must be no appearance money paid for drivers. This is a case of civic pride and the trustees require the directors of the Corona Racing Association to sign a guarantee not to offer any appearance money before the race is allowed to be advertised.

The $15,000 subscribed last Fall when the Corona race was first suggested, is still in the hands of the officers of the association.

According to Chairman Kennerdell, the Corona race will not be a road race this year but a boulevard race. This is a new classification insisted upon by the Chairman of the Contest Board on the grounds that the Corona course was originally designed for speed although it is a public highway.

The next race on the Los Angeles speedway is to be held Feb. 22 and the Corona date, according to supporters, will be March 17. There is some hope of making it a high grade match by getting the International Grand Prix for the course, the Vanderbilt going to the New York Speedway. In case the Corona boosters are unsuccessful in getting the International Grand Prix, the event will be known as the Corona Grand Prix.

2-Mile Speedway for Cincinnati

CINCINNATI, OHIO, Jan. 7—Cincinnati is to have a 2-mile speedway within six months, according to plans of the Cincinnati Speedway Co., organized here with a capital of $500,000 of which $400,000 has already been subscribed. At a meeting of the board of directors last Saturday authority was given to purchase a tract of land 1 mile long and 1½ miles wide near Sharon, Ohio, and lying close to the Big Four, Pennsylvania and Cincinnati, Hamilton and Dayton Railroad lines. There are four improved pikes surrounding the track on which it is planned to erect the new speed saucer. At the Saturday meeting it was understood that the architect, Henry Hake, accompanied by his engineer, Captain Charles Kuck, was to leave within a week to make an inspection of the New York and Chicago speedways.

The plan of construction of the Cincinnati track is to use 2 by 4-in. planks laid lengthwise. There is to be a clubhouse on the field and it is planned to hold military tournaments and general athletic contests on the course as well as automobile races. Through the transportation facilities at the disposal of the company it expects to be able to handle 100,000 persons in half an hour. It is pointed out that 1,500,000 persons live within 100 miles of Cincinnati, which should insure good attendance. The plans for the course are to be ready by February, much of the preliminary work having already been done.

The officers of the speedway are E. W. Edwards, president; Harry Lehman, vice-president, and T. J. Davis, treasurer. The directors, in addition to the officers, are M. J. Freiberg, R. K. Le Blond, J. P. Orr, I. J. Cooper, A. E. Burkhardt, W. T. Foley, T. J. Corcoran.

Elgin May Lose Road Races

ELGIN, ILL., Jan. 7—Elgin may lose the national road races. Negotiations are pending between the Chicago Speedway Assn. and the Elgin Road Race Assn. over a proposition to hold the 1916 races on the Maywood Speedway. F. W. Jencks, general manager of the Elgin events, has arranged for a conference with D. F. Reed, president of the speedway association, to go over the details of the proposition and will present them to the Elgin directors for their consideration. The Elgin association has the option of renting the speedway and taking entire charge, or taking a guarantee from the speedway association and the latter assume the management. Elgin directors hesitate about taking the races away from this city, but they will consider the subject. If assured of financial support from Elgin business men, they will turn down the Chicago proposition. Rains last year proved disastrous to the financial success of the meet.

E. A. Introduces New Rear Signal

BROOKLYN, N. Y., Jan. 7—The E. A. Laboratories, this city, have just perfected a new electrically operated rear lamp signaling device and are making a bid for equipment business. It substitutes for the usual rear lamp with no additional cost.

The E. A. Laboratories, having outgrown their quarters at 627 Kent Avenue, Brooklyn, have just moved into their new building at Broadway and Wythe Avenue, where they expect to produce half a million automobile horns during 1916.

Three More Maxwell Branches

DETROIT, MICH., Jan. 10—The Maxwell Motor Sales Corp. has opened branches in Philadelphia, Atlanta and Providence, in charge respectively of L. G. Peed, C. H. Batchelor and O. C. Reed.

Indianapolis Race Changes

Drivers to Get 25% of Gate Receipts During Practice —33 Starters

INDIANAPOLIS, IND., Jan. 10—Entry blanks for the 300-mile sixth annual race on the 2½-mile brick speedway in this city have been issued, as reported in THE AUTOMOBILE for Jan. 6, and in addition to showing the race of 300 miles for $30,000 in prizes, several other changes as compared with previous Indianapolis races are noted. For the first time the speedway agrees to pay entrants 25 per cent of the gross gate receipts during practice, the distribution of this practice money to be based on the number of laps driven between the hours of 2 and 5 p. m. on practice days. The number of starters has been limited to thirty-three cars and the previous order of eliminating will be carried out so that only the fastest thirty-three cars of all entrants will start. The management insists on the use of steel or bronze spiders on the steering wheels, requires chain-driven cars to have chain guards, and leaves the safety of all other parts of the car, such as steering parts, front axle, etc., to the judgment of the speedway technical committee.

80 M.P.H. Required

The American Automobile Assn. rules will apply in all details including the entry of five cars of the same make. Instead of cars having to qualify at a speed of 75 m.p.h., the figure has been raised to 80.

Tacoma Speedway Race Aug. 5

TACOMA, WASH., Jan. 7—The Tacoma Speedway Assn. announces that the principal racing event of 1916 will be held on Aug. 5, and that the prize for the one race will be $10,000, with a distance of approximately 300 miles, with intermediate prizes for the 100 miles, and the 200 miles.

The big race of the year will be a combination of the Montamarathon and the Potlatch trophy races, and will be broadened into a race for the whole Northwest, and has not yet been named.

Lien Against Sheepshead Speedway—Will Not Affect Operation

NEW YORK CITY, Jan. 10—A lien has been brought against the Sheepshead Bay Speedway Corp., owner of the 2-mile motor speedway for $203,437. The speedway has for many months refused to pay this construction item on the ground that there has been an overcharge of approximately $100,000. The speedway had previously agreed to settle on this basis, but as the contractor has refused, the matter has gone into the courts. The case will not come up for hearing inside of a year and will in no wise affect the speedway, the finances of which are in ample condition to take care of all indebtedness. To date the speedway has a total investment of $3,550,000 made up of property, real estate, $2,050,000, and track, grandstands, and other improvements $1,500,000. The real estate embraces 430 acres of land. Part of this land lies outside of the grounds and is being sold for building purposes.

45 Car and Truck Exhibits at Cleveland Show

CLEVELAND, OHIO, Jan. 8—Although the doors of the Wigmore Coliseum were opened for visitors to the fifteenth annual Cleveland automobile show at 1 o'clock, the formal opening did not take place until 7.30 in the evening. Through the afternoon, however, there was a constant throng of people looking over the forty-five exhibits of automobiles and trucks. Three manufacturers are exhibiting electric cars. One of them showed two models; another, three, and the third showed four.

The number of chassis shown seems rather small, considering the fact that they are always given great attention.

Two local companies, the Peerless Motor Car Co., and the White company, made special displays of the trucks turned out at their plants. Peerless showed its 2-, 4- and 5-ton trucks, all 32.4 hp. White displayed a complete 45 hp. truck and chassis of a 45-hp. and three 30 hp. trucks. Several other light trucks and delivery wagons were shown, including the Baker electric 1- and 2-ton trucks.

Among other exhibits of the Gabriel Auto Co. was a bus built for the Green Line Bus Co. which operates a line between Cleveland and Strongsville and, when this new car is added, will extend the line to Medina. The bus is built to resemble a street car and is equipped with rattan seats with a capacity for seating twenty-one people. It is equipped with a 40 hp. engine and the tires are 36 by 6.

The White company has on exhibition a car with seating capacity for twenty persons. It is equipped with the usual White engine and the body is built something on the order of a sight-seeing car. However, the seats are placed crosswise, with an aisle down the center.

Cars Reduce Kansas R. R. Earnings

TOPEKA, KAN., Jan. 7—Railroad officials state that a disastrous slump in local passenger business has been occasioned by the large number of automobiles in Kansas and as a consequence have asked for an increase from 2 cents a mile to 3 cents on passenger rates.

Milwaukee Show Opens

56 Makers Represented—Show Caters to 4,000,000 People —Trucks Exhibited

MILWAUKEE, WIS., Jan. 8—The eighth annual show of the Milwaukee Automobile Dealers', Inc., opened last night, in the Milwaukee Auditorium and attracted the largest first-night crowd ever known here, or 4790. A total of fifty-six manufacturers are represented by exhibits.

As in past years, the entire basement of the Auditorium is devoted to exhibits of trucks, commercial cars, bodies, and heavy parts and supplies.

The Milwaukee show, like its predecessors, is principally a retail selling proposition, although it ranks high as a booster for the sales by State or district agents to sub-dealers from all parts of the State.

It is estimated that more than 1500 garage-keepers, repairshop owners and agents from every section of Wisconsin attend the January show. With this in view, various organizations select the January show week for the important conventions of the year, notably that of the Wisconsin Retail Automobile Dealers' Association. The M. A. D. annually entertains the visiting tradesmen at a monster banquet, which this year will be held Wednesday evening, Jan. 12, after show-closing time, 10:30 p. m. More than 700 acceptances have been booked.

The Milwaukee show is the principal one between Chicago and Minneapolis and caters to a total population estimated at 4,000,000 people.

Cincinnati to Stop Reckless Driving

CINCINNATI, OHIO, Jan. 10—The city authorities and the judiciary of Cincinnati have both taken up the question of obediance to traffic rules and ordinances and the result is a more stringent observance of the laws which are now in force. Steps are also being taken to have enacted more rigorous laws for the control of traffic on the streets of the city.

Safety Director W. J. Friedlander. acting under instructions from Mayor Puchta, has issued orders to the police to place reckless drivers of automobiles and motor trucks under arrest and to force them to furnish bonds, instead of being cited to appear in court.

Hercules Motor Completes Organization

CANTON, OHIO, Jan. 6—The Hercules Motor Mfg. Co., this city, recently organized to build automobile motors, has completed its organization by the election of Charles Balough, president; Gordon M. Mather, vice-president, and O. J. Strayer, secretary and treasurer. Mr. Strayer is at present secretary and treasurer of the Canton Stamping & Enameling Co. Others on the board of directors are H. H. Timken of the Timken Roller Bearing Co., J. G. Obermier and L. Pulcher.

Reo Employees Get Christmas Present

LANSING, MICH., Jan 3—A $5 gold coin was given as a Christmas present to every employee, either in the shops or in the offices, of the Reo Motor Car Co., and of the Reo Motor Truck Co. All told, 4500 employees were in line, which means that the companies distributed $22,500 in gold.

Star Rubber to Start Work

AKRON, OHIO, Jan. 7—The Star Rubber Co., which has been making automobile sundries, is to begin the manufacture of automobile tires. For this purpose a three-story building 70 by 100 ft. will be put up at a cost expected to be about $30,000.

Dunham Body Factory Burns

NEWARK, N. J., Jan. 10—The plant and show rooms of the D. B. Dunham & Sons, Inc., manufacturer of automobile bodies, were destroyed yesterday by fire, entailing a loss of $100,000.

Larrabee-Deyo Truck Makes Lease

BINGHAMTON, N. Y., Jan. 7—At a meeting of the directors of the Larrabee-Deyo Motor Truck Co., arrangements were perfected to lease part of the main building of the Sturtevant-Larrabee Co. for the manufacture of trucks.

Goodyear Opens Station in Dakotas

ABERDEEN, S. D., Jan. 7—The Goodyear Tire & Rubber Co. has opened a service and sales station here to cover northern South Dakota and southern North Dakota. H. F. Brownell Co., Sioux Falls, state agent, will manage the new station here.

Van Sicklen Speedometer on 1916 Stutz

NEW YORK CITY, Jan. 7—Announcement was made at the automobile show in this city that the Van Sicklen Co., Chicago, Ill., will equip all cars made by the Stutz Motor Car Co., Indianapolis, Ind., with its speedometers.

Mitchell Eight $1,450

NEW YORK CITY, Jan. 7—In the Dec. 30 issue of THE AUTOMOBILE the price of the Mitchell eight was given at $1,250. The Mitchell company would like it announced that the price of this car is $1,450 f.o.b. Racine, for either three-passenger roadster or seven-passenger touring car.

Factory Miscellany

Cleveland-Ford Tire to Build—The Cleveland-Ford Tire Co., Ashtabula, Ohio, will soon start the erection of its plant.

Heinze to Add New Equipment—The John O. Heinze Co., Springfield, Ohio, contemplates installing additional equipment to its plant.

Ford Addition in Denver—The Ford Motor Co., Denver, Colo., will build a four-story addition to its assembling plant. The estimated cost is $150,000.

Harvey Top Starts Manufacturing—The Harvey Auto Top Co., 4050 Easton Avenue, St. Louis, Mo., has begun the manufacture of winter or convertible tops.

Link-Belt to Add—The Link-Belt Co., Indianapolis, Ind., will build an addition to its plant at Addison Street and the Vandalia Railroad, the estimated cost being $12,000.

Crow to Add—The Crow Motor Car Co., Elkhart, Ind., has awarded contracts for an addition to its plant which will be 60 by 240 ft., and will cost approximately $10,000.

To Make Tires in El Paso—J. Thomas Ward is organizing a company to build an automobile tire and tube manufacturing plant at El Paso, Tex., the estimated cost being $200,000.

Fuelton-Greuter to Move Plant—The Fuelton-Greuter Mfg. Co., Saugas, Mass., manufacturer of carbureters, will remove its plant to Cincinnati at an early date. A building at the corner of Sixth and Baymiller Streets has been leased.

Overland's Toledo Building Plans Changed—Plans for the Willys-Overland service building to be erected at Adams and Fourteenth Streets, Toledo, Ohio, have been changed in order to secure a larger structure. The new plans call for a fireproof structure, four stories high and 100 by 280 ft. The cost of the building will exceed $100,000.

Baldwin Locomotive Truck Plant—The Baldwin Locomotive Works, Philadelphia, is erecting a one-story factory building at its Eddystone property in which it will manufacture motor trucks exclusively. These trucks are for foreign service.

Mitchell-Lewis Improvements — The Mitchell-Lewis Motor Co., Racine, Wis., is installing an additional 300-hp. boiler and making other improvements to its power and generating facilities to accommodate the increased demand of its big plant. Immediately after Jan. 1 the force was increased and overtime schedules made effective in numerous departments to bring the production of cars up to the requirements of agents.

The Automobile Calendar

Jan. 7-13	Milwaukee, Wis., Show, Auditorium.
Jan. 8-15	Cleveland, Ohio, Show, Wigmore Coliseum, Cleveland Automobile Show Co.
Jan. 8-15	Philadelphia, Pa., Show, Philadelphia Auto Trade Assn.
Jan. 13-18	Columbus, Ohio, Show, Memorial Hall, Columbus Automobile Club and Columbus Auto Trades Assn.
Jan. 14-22	Dayton, Ohio, Show, Delco Bldg., Dayton Automobile Dealers' Assn., and Dayton Accessory Dealers' Assn.
Jan. 10-15	Fort Wayne, Ind., Show, Auto Trade Assn.
Jan. 10-15	New Bedford, Mass., Show, State Armory.
Jan. 15-22	Detroit, Mich., Show, Detroit Automobile Dealers' Assn.
Jan. 17-19	Erie, Pa., Show, Erie Automobile Dealers' Assn.
Jan. 17-22	Rochester, N. Y., Show, Exposition Park, C. A. Simmons, Mgr.
Jan. 17-22	Wilmington, Del., Show, Wilmington Automobile Show Assn.
Jan. 18-21	Fargo, N. D., Show, North Dakota and Minnesota Automobile Dealers' Assn.
Jan. 18-22	Baltimore, Md., Show, Fifth Regiment Armory.
Jan. 25-29	Lancaster, Pa., Show, Conestoga Park Pavilion.
Jan. 22-29	Montreal, Que., Show, Almy's Bldg., Automobile Trade Assn., Ltd.
Jan. 22-29	Chicago, Ill., Show, National Automobile Chamber of Commerce; Coliseum and First Regiment Armory.
Jan. 24-29	Buffalo, N. Y., Show, Buffalo Automobile Dealers' Assn., Broadway Auditorium.
Jan. 24-29	Scranton, Pa., Passenger Car Show, Town Hall.
Jan. 24-30	Portland, Ore., Show, Armory, Portland Automobile Dealers' Trade Assn.
Jan. 25, 26, 27	Montgomery, Ala., Show, Klein Bldg., Montgomery Automobile and Accessories Dealers.
Jan. 29-Feb. 5	Columbus, Ohio, Show, Memorial Hall, Columbus Automobile Show Co.
Jan. 29-Feb. 5	Minneapolis, Minn., Show, National Guard Armory, Minneapolis Trade Assn.
Jan. 31	Scranton, Pa., Show, Commercial Car Show, Town Hall. H. B. Andrews, Mgr.
Jan. 31-Feb. 5	Fall River, Mass., Show, State Armory. R. C. Borden, Mgr.
Feb. 1-3	Frederick, Md., Show, Armory.
Feb. 1-5	York, Pa., Show, York Auto Dealers' Assn.
Feb. 2-5	Buffalo, N. Y., Show, Auditorium, Buffalo Automobile Mfrs. and Dealers' Assn.
Feb. 2-5	Poughkeepsie, N. Y., Show, State Armory.
Feb. 7-12	Kansas City, Mo., Show, J. I. Case, T. M. Bldg., Kansas City Motor Dealers' Assn.
Feb. 7-12	Duluth, Minn., Show, Armory, Duluth Automobile Dealers' Assn.
Feb. 8-11	Grand Forks, N. D., Show, Auditorium.
Feb. 9-12	Peoria, Ill., Show, Coliseum, Peoria Automobile and Accessory Assn.
Feb. 12-19	Albany, N. Y., Show.
Feb. 12-19	Hartford, Conn., Show, First Regiment Armory, Hartford Automobile Dealers' Assn.
Feb. 14-19	Des Moines, Ia., Show, Des Moines Auto. Dealers' Assn.
Feb. 14-19	Winnipeg, Man., Show, Ford Plant, Winnipeg Motor Trades Assn.
Feb. 19	Newark, N. J., Show, First Regiment Armory, C. G. Fitzgerald, Mgr.
Feb. 20-27	Grand Rapids, Mich., Show, Klingman Furniture Exhibition Bldg., Automobile Business Assn.
Feb. 21-26	Bridgeport, Conn., Show, State Armory. B. B. Steibler, Mgr.
Feb. 21-26	Louisville, Ky., Show, First Regiment Armory.
Feb. 21-26	Omaha, Neb., Show, Omaha Automobile Show Assn.
Feb. 21-26	Portland, Me., Show, Exposition Bldg.
Feb. 21-26	South Bethlehem, Pa., Show, Coliseum. J. S. Elliot, Mgr.
Feb. 21-26	Syracuse, N. Y., Show, Syracuse Automobile Dealers.
Feb. 28-Mar. 3	Pittsburgh, Pa., Convention of American Road Builders' Assn., Mechanical Hall.
Feb. 28-March 4	Paterson, N. J. , Fifth Annual Show, Auditorium.
Feb. 29-Mar. 4	Ft. Dodge, Ia., Show, Terminal Bldg., Ft. Dodge Automobile Dealers' Assn.
March 4-11	Boston, Mass., Car and Truck Show, Mechanics Bldg.
March 8-11	Davenport, Ia., Show, Tri-City Davenport, Rock Island & Moline; Tri-City Automobile Trade Assn.
Mar. 8-11	Mason City, Ia., Show, Armory.
March 8-15	Brooklyn, N. Y., Show, Brooklyn Motor Dealers' Assn.
Mar. 21-25	Deadwood, S. D., Show, Auditorium, Deadwood Business Club.

May 30	Indianapolis Track Race.
June 17	Chicago Track Race.
June 28	Des Moines, Ia., Track Race.
July 4	Minneapolis Track Race.
July 4	Sioux City Track Race.
July 15	Omaha, Neb., Track Race.
Aug. 5	Tacoma Track Race.
Aug. 18-19	Elgin Road Race.
Sept. 4	Des Moines Track Meet.
Sept. 15	Indianapolis Track Race.
Sept. 16	Providence Track Race.
Sept. 30	New York City Sheepshead Bay Race.
Oct. 7	Omaha Track Race.
Oct. 14	Chicago Track Race.

The Week in the Industry

Pardee Is Diamond-T Sales Manager—Fred Pardee has been made sales manager of the Diamond-T Motor Car Co., Chicago, Ill.

Stanford Is Westcott Purchasing Manager—E. E. Stanford of Indianapolis has been made purchasing manager of the Westcott Motor Car Co., in Richmond, Ind.

Rittenhouse Joins Norwalk Tire—L. K. Rittenhouse, former manager of the St. Louis branch of the B. F. Goodrich Co., has become associated with the Norwalk Tire & Rubber Co., Norwalk, Conn. O. E. Hoerger, former assistant branch manager of the St. Louis Goodrich office, is now acting manager.

Dealer

Overland Factory Office in Seattle—The Willys-Overland Co. will establish a factory office in Seattle, Wash., controlling the territory of Washington, Oregon, Idaho, Montana and British Columbia. Offices will be opened at the plant of J. W. Leavitt & Co., which remains the distributer of the Overland. This company will augment its office staff by moving there W. J. Pedlar, at one time its San Francisco manager, who will be supervisor in the Northwest at Seattle.

Philadelphia Trade News—J. R. McClellan, manufacturer and sales agent of the McClellan tire, will retail that tire, together with the Chester tire and Efficiency gas oil, at 817 North Broad Street.

The George W. Reinbold Co. is erecting showrooms and service station at 2506 North Broad Street, the home of the Scripps-Booth car.

The Metz Co. has opened new showrooms at the southwest corner of Broad and Wood Streets.

Overland Makes N. Y. Lease—The Willys-Overland Co. has leased the Conrad Stein Brewery property, running through the block from Fifty-seventh to Fifty-eight Streets, near Eleventh Avenue, New York City. A new concrete, eight-story building, which is to be 150 ft. wide by 200 ft. deep, will be fitted out as zone offices and general headquarters for the New York zone. The entire upper part of the building will be occupied by the wholesale establishment while the lower part will be sublet to the C. T. Silver Motor Co., the New York City distributor, as a service station for its customers.

Motor Men in New Roles

Drawe Resigns from Pathfinder—G. E. Drawe has resigned from the Pathfinder Co., Indianapolis, Ind., and is now assistant general manager of the Allen Motor Co., Fostoria, Ohio.

Kimball Makes Change—Wade Kimball, formerly sales manager of the Moreland Motor Truck Co., has assumed the duties of manager of the Pacific Metal Products Co.'s truck and tractor department, Los Angeles, Cal.

Montgomery Joins Standard Truck—G. M. Montgomery, formerly traveling representative for the Bessemer Motor Truck Co., has been appointed eastern traveling representative for the Standard Motor Truck Co., Detroit, Mich.

Flint Heads Los Angeles White—G. M. Flint has been placed at the head of the pleasure car department of the Pioneer Commercial Auto Co., Los Angeles, Cal., which controls the southern California and Arizona agency for the White products. Mr. Flint for the past two years has been manager of the local Moline branch.

Spencer Moline Mgr.—L. R. Spencer has been appointed sales manager of the Los Angeles Moline Automobile Co., factory branch. For the past two years Mr. Spencer has been in charge of the service for the company in this territory and previous to his coming to Los Angeles was connected with the sales department at the factory.

Gallmeyer Transferred to Fort Wayne—E. G. Gallmeyer, district manager for the S. F. Bowser Oil Tank & Pump Co., Fort Wayne, Ind., has been transferred from Louisville, Ky., where he was manager of the Louisville branch, to Fort Wayne, where he will act as editor of the Bowser Boomer, the monthly publication of the company. A. D. Carriger will succeed him at the Louisville branch. G. A. Townsend, Jr., advertising and publicity manager for the Bowser company has acted as editor of the Boomer but on account of the increase in business he would be unable to look after getting out the publication. The fourth annual convention of the Bowser Pacemakers has been in session at the home office during the past week. One hundred and seventeen salesmen this year are members of the club.

Chouteau Made V.-P.—August Chouteau has been made vice-president of the Bittel-Leftwich Tire Service Co., St. Louis, Mo., and will take an active interest in the business.

Wilkinson Blair Mgr.—R. L. Wilkinson has been appointed general manager of the factory of the Blair Motor Co., Newark, Ohio. R. C. Hammond has been elected secretary-treasurer of the company.

Metcalf Joins Philadelphia Houk—W. H. Metcalf, heretofore associated with the management of the Bartlett garages, and secretary of the Philadelphia Motor Truck Assn. since its organization, will in future have charge of the Houk wire wheel interests in Philadelphia, with headquarters at 328 North Broad Street.

Dealer

New Detroit Body Co.—The Beach-Cross Body Co., Detroit, Mich., has opened for business at 863 Woodward Avenue, handling the product of the Highland Body Mfg. Co., Cincinnati.

New Detroit Firestone Home—The new home for the Detroit branch of the Firestone Tire & Rubber Co., will be a four-story structure, 181 by 300 ft. at Woodward and Canfield Avenues. It will be started at once and is expected to cost between $30,000 and $50,000.

L. I. Site for Pierce-Arrow—The Arrow Motor Realty Co., representing the interests connected with the Harrolds Motor Car Co., agent for the Pierce-Arrow automobile, New York City, has purchased an entire block in Lond Island City, directly at the rear of its service building erected last year, involving the property bounded by Freeman and Webster Avenues, Fifth and Sixth Streets.

Omaha Goodyear Again Adds—For the third time since occupying its new quarters last spring, the Omaha, Neb., branch of the Goodyear Tire & Rubber Co., has been forced by the development of trade to add to its floor space in very material degree. The last move will increase the space by about 3500 ft.

When the branch first moved in, it had about 5000 ft. of floorspace. It now has 14,000, and the latest move, besides including extensive remodeling within the building already occupied, involves also the occupying of the basement of an adjoining building. After the first of the year, the branch will have a district credit office and a district mechanical office, with special men to handle these new goods. The sales force will have been increased to twelve men.

Vol. XXXIV New York—Thursday, January 20, 1916—Chicago No. 3

The Automobile

1916 Body Design Is Uniform

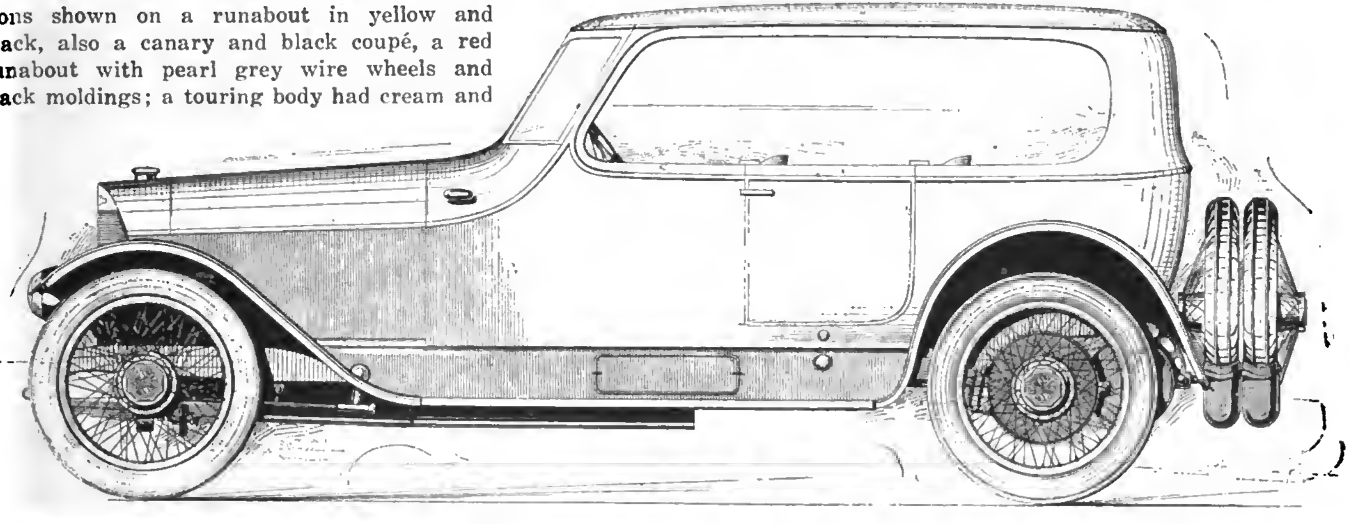
Best of Last Year Is Now Average. Form, Color and Comfort All Improved at Both Palace and Astor Shows

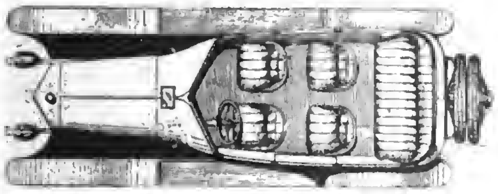
By G. J. Mercer

THE Palace and Astor Hotel shows just concluded, present in the body designs displayed, a more uniformly worked out plan to develop the streamline effect, than in previous years. This is particularly noticeable in the fore part of the car, and in both shows, with the exception of a negligible number, the line from the radiator to the body both on the sides and the top, presents a graduated surface, so that viewed from a distance, in many cases it is difficult to determine just where the engine hood ends and the body proper commences.

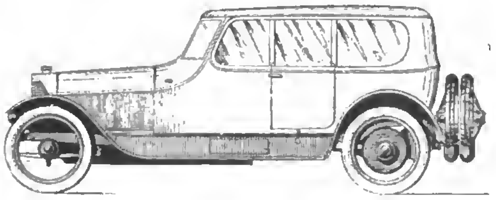
The Palace exhibition outshone all previous years in color combinations, there were very good combinations shown on a runabout in yellow and black, also a canary and black coupé, a red runabout with pearl grey wire wheels and black moldings; a touring body had cream and brown with Spanish leather. There was a dark grey sedan and a very pleasing grey and black sedan; a dark grey limousine, a coffee and black touring body, a wine colored coupé, a green and black touring body, a wistaria sedan, a white and grey limousine and a white and black limousine. These are a few of the best combinations, most were in good taste, only a few violated the rules and had combinations that made a glare in place of a pleasant sensation.

In the Astor show the color combinations were less conspicuous than at the Palace, grey or white and black, and yellow and black were used, but not extensively, and the trim-



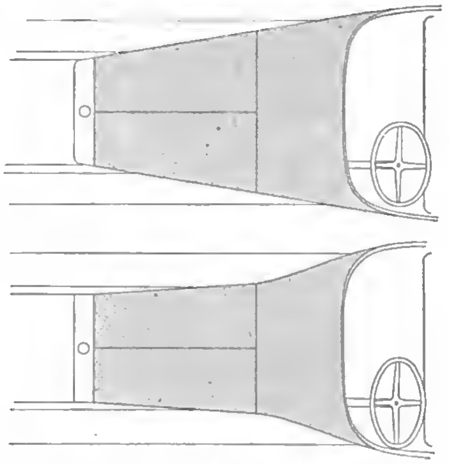


A new style body by Bender and Robinson on a Singer chassis at the Astor show



mings were suitable to match the car colors; in one Armstrong closed body, and in one Holbrook open body, a soft undressed leather trimming was used; the majority had the regulation cloth goods with dark leather for the front seats.

In the following not all the good things at the shows have been enumerated, nor have all the commendable designs been illustrated, but to the best of the writer's ability, those things that are of interest to the greatest number have been given prominence. Both shows serve their separate purpose and as long as one is not a duplicate of the other there will be room for both, one the manufacturers' exhibit of standard make, and the other special designs particularly in bodies, for those that are desirous to have automobiles custom made.



Figs. 1 and 2, showing plan views of two bodies with contrasting cowl taper

Smoother Bodies at Palace

Returning to the consideration of body shapes as noticed at the Palace show the first point is that the sides of the bodies have a smoother surface, due to the absence of moldings. This is true even of the doors, where the customary tee molding has been replaced by allowing the panel sheet to extend and cover the door openings. The top line of most of the touring bodies and runabouts and the driving compartment of closed bodies show rounded edges and on these closed bodies the overlap panel in which moldings are not used to join the upper and lower panels, was the rule and not the exception, also the seat trimming roll does not show above the body line, or if it does, it is very much reduced in size over former years.

There are fewer slanting windshields than was to be expected, considering the general desire to eliminate wind resisting surfaces, but there are more shields placed on top of the cowl panel and forward of the rear edge of the cowl and there are fewer cowls having the extreme upward tilt to the top line, near the shield seating.

Touring Body Holds Position

The touring body still holds its own as the most representative member of the automobile family, and the type with a second cowl, not only shows a large increase in numbers, but the effect of its popularity is proved by the desire to imitate it, by minimizing the height of the driving seat back, and in some cases, rounding it to give the appearance of half a cowl. This tends to give the bodies a lower appearance and the elimination of the trimming rolls helps to accomplish this end. In reality the bodies are lower, measured at the seat back, but the sides are slightly higher; 24 to 25 in. is the average side panel height. The aisle between the driving seat also shows gain in numbers and in some cases the second cowl itself is divided.

The disappearing seat, despite the fact it is not so roomy as the older form of side seat, has proved to be the only style that is acceptable on both open and closed bodies, and the most popular is the one that folds into the back of the driving seat.

The four-passenger clover leaf runabout is the new idea this year. Last year there was one three-passenger body, and while, now, the majority on exhibition were only comfortable seating for three, there were two, the rear seat of which could accommodate two adults and one of these bodies was 42 in. wide on the cushion by 24½ in. from trimming or rear seat to panel of front seat.

One expected to see quite a number of good looking designs of demountable tops fitted to touring and runabout bodies, the demountable top has been featured so much in automobile advertising of late, that naturally we looked for a better showing than there is. The Kissel, which is one of a very select few that look like jobs, showed one car with the inside stripped of its trimming, showing the method of attaching and detaching the upper section so it could be readily understood. The other tops exhibited have the effect of marring the general clean look of the body by the excessive width of the framing pillars, which only proves that to make a successful demountable top, it must be made with the body as part of the original design and not added as an afterthought.

The permanent-roof body shows increased numbers over last year. The regular Springfield body is on a number of cars and there is an adaptation of the Springfield idea on two others. Pierce had a body of this type in which the pillars fold down inside and are fitted with an automatic hinged arm for holding them in their respective positions. The only full collapsible all-weather body was exhibited by the Springfield Metal Body Co.

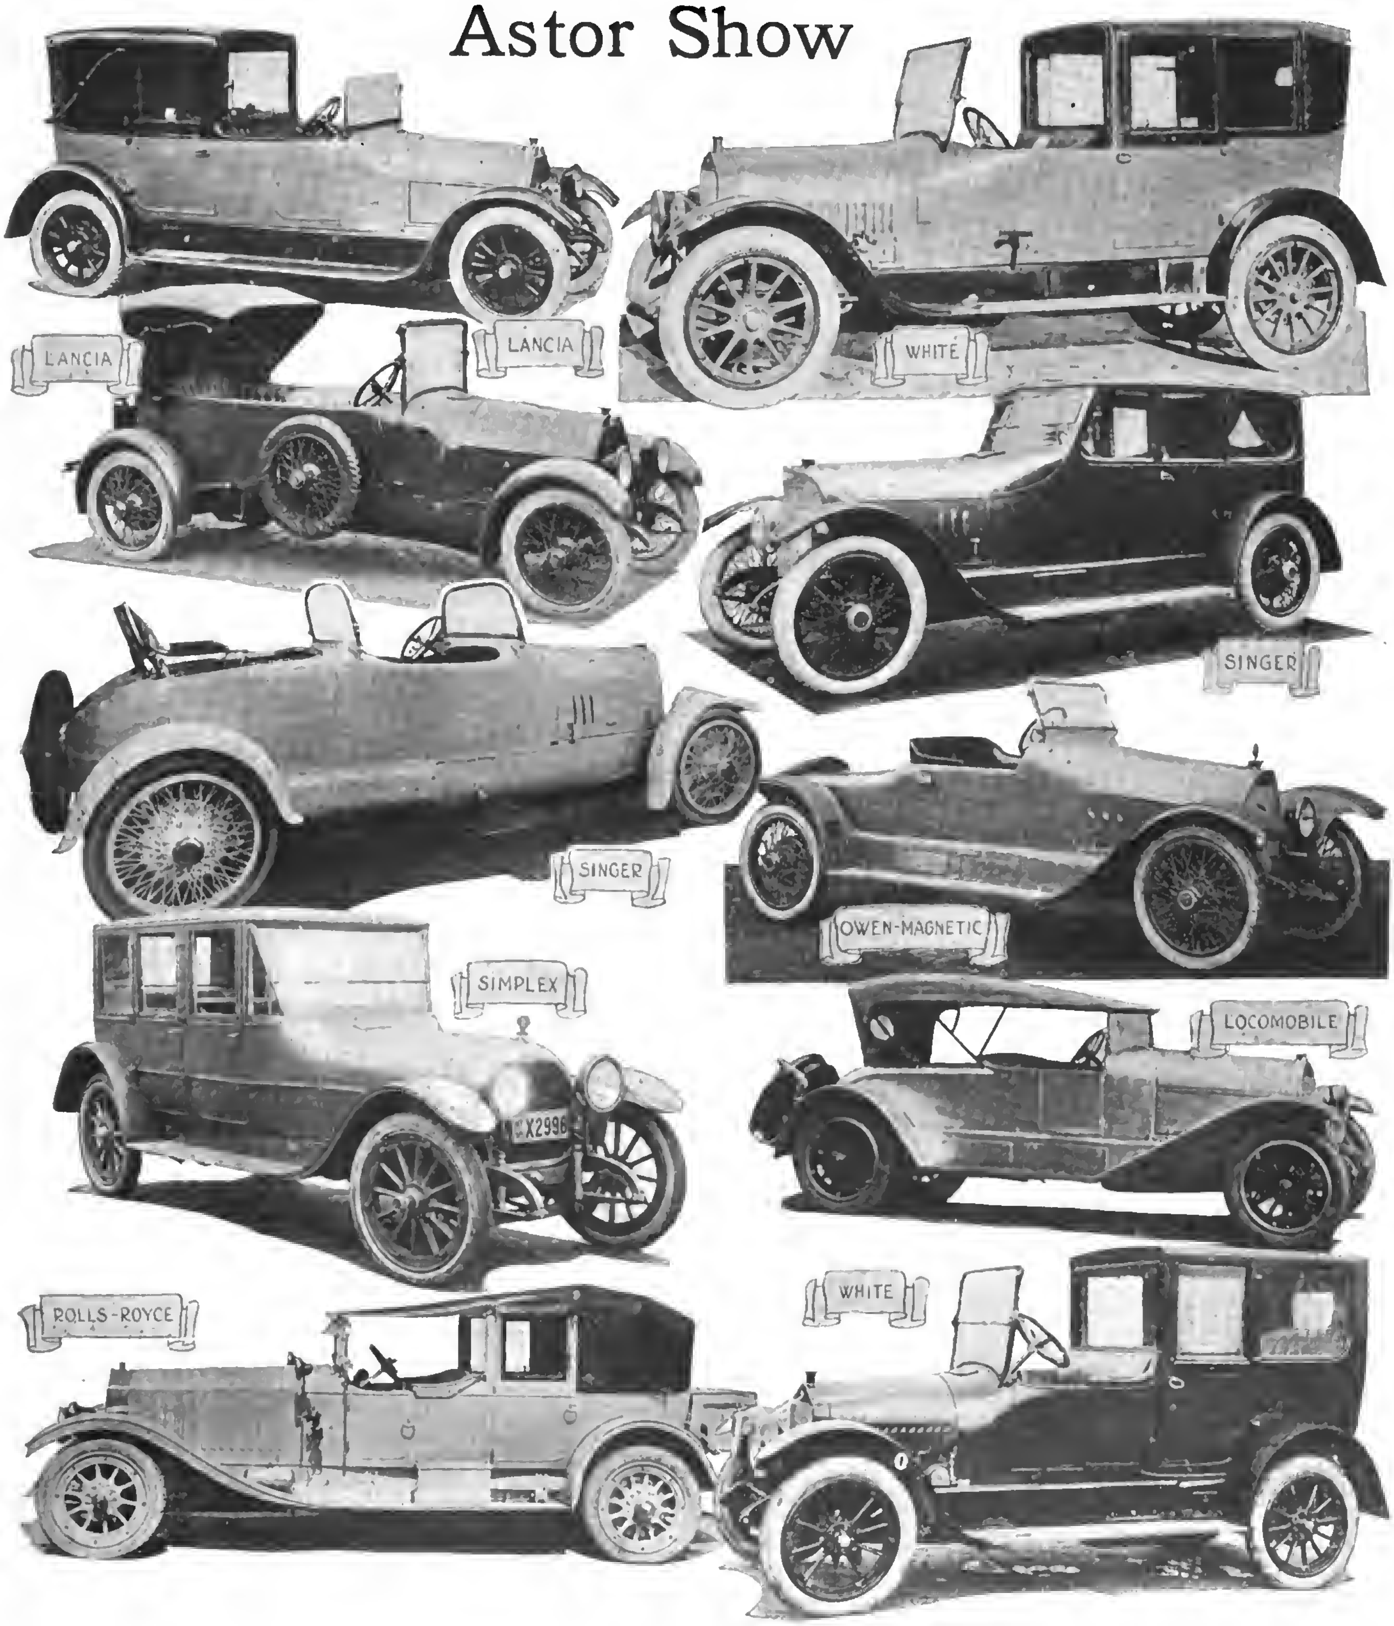
Few Innovations

The Palace show from a body point of view, had practically no features that were innovations, the *average* this year was virtually the duplicate of the *best* in the show last year and many of those that excelled last year, had the same exhibit this time. The Palace average was very good in finish, design and workmanship and novelties were conspicuous by their absence. There were fewer closed bodies in proportion to the total exhibit than formerly, but town cars, which have never been very numerous at this exhibit, were about the same in number and are of better design than formerly, but there is one feature in which this show outdid all its former records, and that is in colors. Hardly an exhibit but had its white or white and black, or yellow and black, or grey, or some other light color, and the striping of the hood and wheels was louder and more prominent than ever.

The word streamline has become the synonym for the latest in body design and is used indiscriminately for every body that shows a tapered line from the radiator to the cowl. Truthfully speaking the only bodies that approach the true streamline effect are the runabouts. To understand this, imagine a shape exactly like an egg placed on wheels, the large end toward the front, as the egg moves forward separating the air, the pressure of the atmosphere is increased by the displacement, and as the air currents pass along the sides, due to the egg moving forward, they meet easily and without clashing at the tapered rear end, and no revolving eddies or air currents are set up to disturb the road dust as the body passes forward. No body design in the near future is going to be built along these ideal lines, except the beforementioned runabouts, no real necessity exists to disproportion the rear end of a limousine or a touring body to make it egg-shaped and there is also the item of additional cost of construction. The fore part of the body that breasts the wind, is the part that has a commercial value, and eliminating the flat surfaces at the front and on the sides is the real money saver. Summing up the above logic, the writer suggests that "fore-streamline" would be a more applicable term to use, as it would cover all that we are trying to accomplish in body designing at the present time, that is, giving the front of the car the minimum of resistance.

Figs. 1 and 2 show the plan view of the hood and cowl of two touring bodies at the Palace, Fig. 1 is the newest de-

Some Examples of Typical Bodies at the Astor Show



THE Astor exhibition is always productive of many different styles of body construction. Both old models and the most advanced examples of modern tendencies may be seen side by side. The ten bodies shown here are representative of most of the new ideas and it will be noticed that the Astor show, like that at the Palace, contained many examples of the clover leaf. The number of comparatively small capacity bodies is also noteworthy, though many were very large.

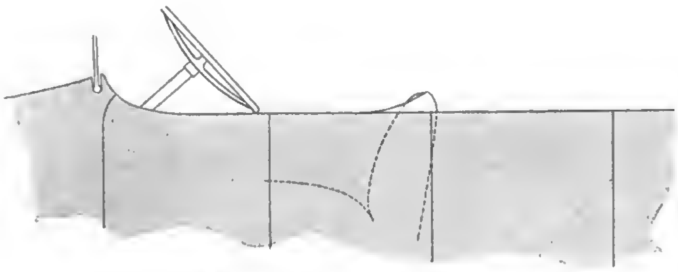


Fig. 3—Example of lowered back driving seat

sign and there is a taper of approximately 6 in., each side in the length of the hood. The body line continues from this without a ripple, to the widest part, this being a fine example of a fore-streamline. Of stock cars the Mercer is one of the best of this class. Fig. 2 is an example of one of the more conservative makes of cars, it marks a slower growth and lacks the bold straight appearance that characterizes Fig. 1. The top line of the hood has the same appearance on most cars as the side line of Fig. 1, from radiator to dash, the average raise is 2 to 3 in., the radiators are similar to last year, those with the slightly rounded edges predominating.

Figs. 3 to 8 are sketches of Palace show bodies.

Fig. 3 is an example of the lowered driving seat back rounded over like half a cowl, on this particular body the back below the cowl had two compartments that are used to stow away the top curtains.

Fig. 4 shows a runabout deck cover supported in the open position by arms that travel in slides at the bottom and drop into pockets at the slide end when raised.

Fig. 5 shows the rear seat of a runabout and the method of locking the lid in position to form the back, it shows a cheap way to make a seat in a small rear compartment and still be able to raise the lid when the top of the car is down.

Kissel All Year Is Sound Job

Fig. 6 is a diagram of the interior of the Kissel demountable top body, *A* shows the lock that fastens the upper part of the door to keep it from rattling, it engages in a plate in the body pillar and is operated by *B*, this lock is operated by the inside or outside handle and the push rod moves up and raises *A* and when the handle is released *A* drops into its place in the pillar, the push rod rests in the lock *A* and disengages itself when the top section of the body is lifted off; *C* shows the attaching lugs; the bolts used to fasten these are always accessible, being covered by flaps in the trimming.

Fig. 7 is a four-passenger runabout adapted from the clover-leaf idea the plan view shows the seating arrangement and the second cowl is divided by a passage way.

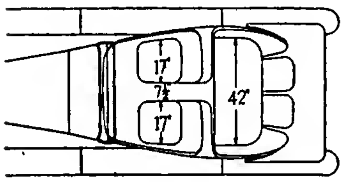
Fig. 8 is the outline of a town car body on the Owen Magnetic, there is only one door for the driver on the right side, the glass space at the front is unusually large and has rounded top corners, the driving compartment is joined to the body by a second cowl; this body was one of the best designs exhibited.

Low Appearance Favored

The coefficient of streamline in body nomenclature is *low looking* and the effort to produce this effect has replaced 36-in. tires with 34 and 32 sizes, the running board has come nearer the ground and a little additional kick up to the chassis frame sends it down forward of the rear wheel. The double drop to the frame has not had many converts. Pierce did this in place of reducing the tire size. The optical effect of raising the hood and cowl helps to make the touring and runabout look lower, but the greatest gain has been in lowering the seats, since the gasoline tank has been placed at the rear. The driving seat has been lowered 3 in. on touring and about 6 in. on runabouts and the slant of the cushions is about 2½ in., so that on touring bodies the driver actually is about 5½ in. lower when seated than formerly. The seats have been moved farther back to allow the extra leg room required when seated low and the steering wheel has been lowered and the column lengthened to accommodate the seat, in many bodies the driving seat is now made adjustable, because the driver sitting more straight out than formerly, it is not practical to expect men of different heights to accommodate themselves in the same sitting space. At present this is only done on touring and sedan bodies where the aisle between the seats makes the driving seat a free agent. On closed bodies, such as limousines, etc., the driving seat is much the same as formerly, on account of the necessity of having the door to the body as large as possible, and the driver is placed as far forward as freedom of movement and the proper room to sit will permit.

Cushion Height Decreasing

The average height of the front and back seat cushions from the floor at the front of the cushion is 15 in. on touring bodies with an average slant of 2½ to 3 in. This applies to the rear seat in closed bodies also. There are a few touring bodies in which the rear seat cushion is only 12 in. up, but this is a height that no woman can either sit down on or



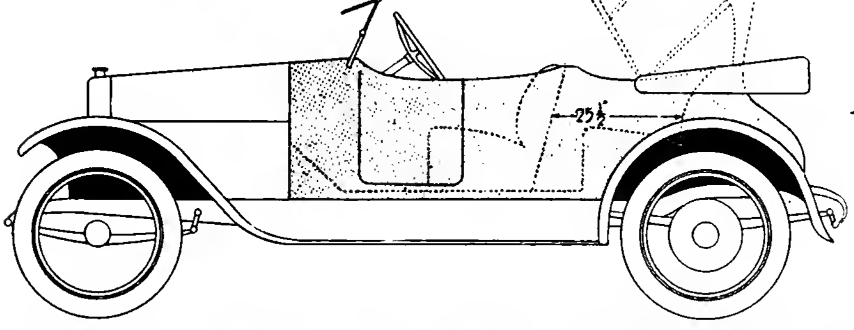


Fig. 7—Side and plan views of a good four-passenger roadster.

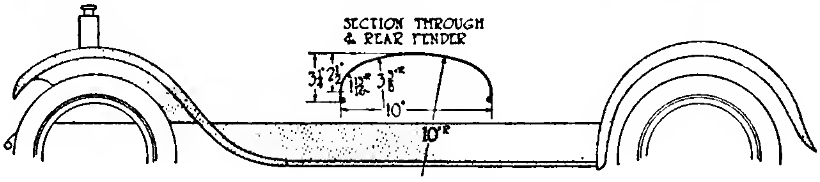

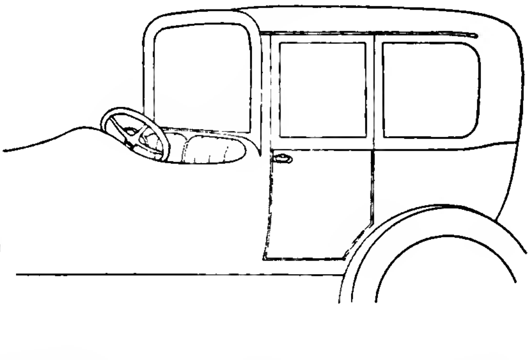

Fig. 8—A well-proportioned town car. Fig. 9—Proportions of Chalmers front and rear fenders

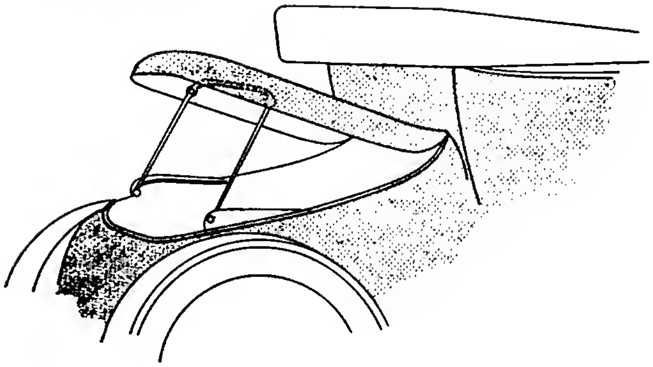

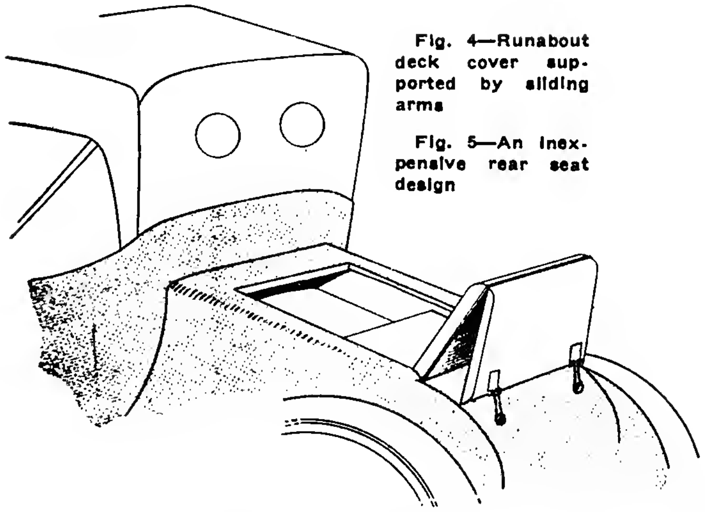

Fig. 4—Runabout deck cover supported by sliding arms

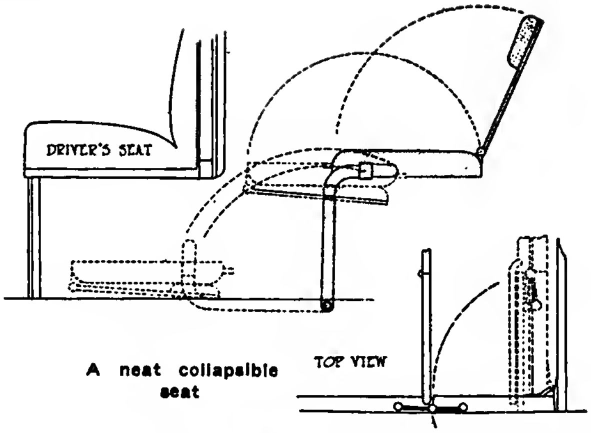
Fig. 5—An inexpensive rear seat design



A neat collapsible seat

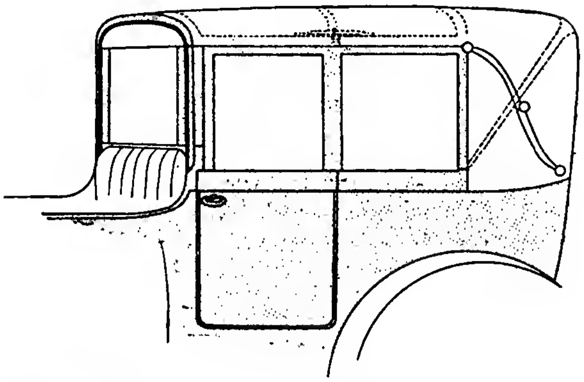


Fig. 10—Healey Holbrook folding top semi-touring car

get up from comfortably. The average height inside from floor to under roof in closed bodies is 55 in. One body at the Salon had only 50 in. height and there are several that are only 53 in. Years ago 58 in. was considered the proper height and from present indications 54 in. will be the average height for all stock bodies. The average height of the seat back on touring bodies is 15 in. for the front and 18 in. for the rear.

The instrument boards on nearly all the cars seen at the Palace are similar designs to last year, and though arranging the indicators in this manner gives the car a machine-like look, there is a disadvantage and expense when the bodies are changed, and there was more than one comment that this is a thing that is being overdone and should be made less prominent. One body at the Astor Hotel had the clock and speedometer at the rear of the driving seat and the balance of the indicators on the dash just above the toe boards, this left the cowl free and clean-looking and one felt that it would be easy to enter this body and not bump the shins, although the seat was very low. It is safe to predict that a year hence will see a change in the location and appearance of this feature.

One Person Tops Universal

At the Palace one-person tops were used exclusively, a few touring bodies had victoria top, there were more wire wheels used than last year and the dash lamp was only noticed on two makes of cars, the extra shoes or tires were carried in nearly every case at the rear and there were more guards of the crown type than ever. Fig. 9 shows the Chalmers front and rear guards and the cross-section shows the shape of the top line. The trimming material of the touring and runabout bodies is mostly leather, a few have the imitation and a few Spanish leather with fancy colors. Only one body in the show had the Turkish style of trimming, all the rest had either the straight pipe with few buttons or the older form of pipe and point.

The electrics from a casual glance appeared like the display of last year, except that there was less conspicuous trimming used inside and more color used in the outside painting.

The closed bodies were modest in design, no job had the full rounded or extreme dip to the roof line, there was a tendency to flatter roof shapes, two bodies had chauffeur lights, nearly all had the double vision windshield and regulators were used on the windows almost exclusively. Several had fancy trimming combinations and some had the broad black and white striped trimming, this was nearly always accompanied by white and black painting on the body and chassis. The coupelet designs were identical with last year and the coupés were all large and had the extension window forward of the door, and room for four inside.

At the Salon there was enough new in body construction to satisfy the exacting and the curious as well as those who are really interested in watching progress. The new bodies were practically all closed ones this year as against previous years when open bodies represented the bulk of the innovations.

The exhibits of Brewster, Healey, Lock, Bender & Robinson and the foreign bodies of Barker & Co., as well as the bodies of the Fleetwood Metal Body Co. and Hayes & Miller Co. all came in for their share of notice. Fig. 10 is a semi-touring body, Healey and Holbrook showing some of this type. The top is fully collapsible and the ease with which

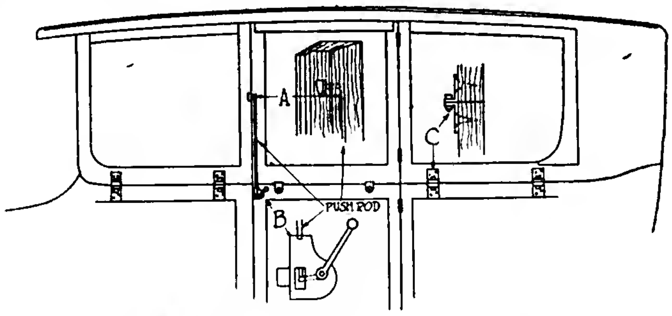

Fig. 6—Diagram of Kissel "All Year" body

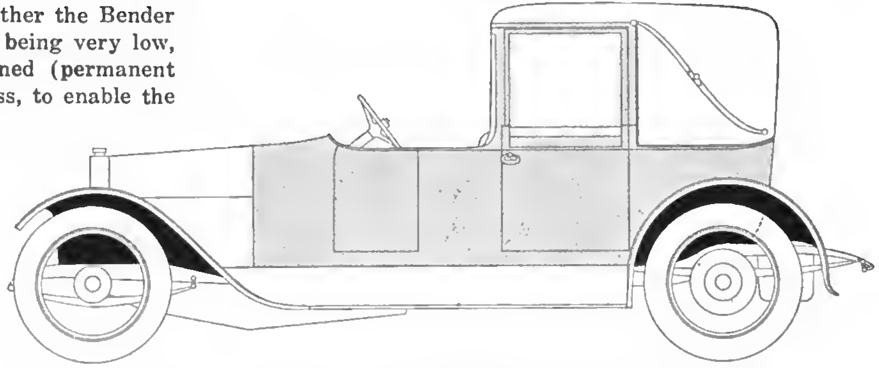
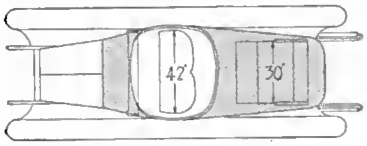
one man can operate it was demonstrated at stated intervals on the Healey body at the Locomobile exhibit. At the rear pillar are landau springs to assist in carrying the weight while lowering and raising. The front pillars fold down, and the manner in which the top part collapses is indicated in the diagram plan view; the top is of leather and is lined inside in light grey cloth. The body makes an attractive design, having the advantage of being easily converted into a closed, and open car, or the sides can be entirely opened after the manner of the well understood permanent roof bodies. Fig. 11 is also a Healey production, and has one of the two new folding seats at the shows; the method of operation is clearly depicted in the drawing. Its advantage is that it is folded away horizontally, and the pocket to receive it will not be high enough to prevent the glass in the front division from dropping its full length, as is the case when the ordinary type is let into the partition.

V Windshield Types

Fig. 12 is a V-type windshield Sedan exhibited on the White, it is painted in white and black, and the trimming corresponds; the roof is leather covered and it makes a very neat, compact body that is not too extreme to suit the taste of refined people. There was another V windshield body shown by Holbrook that was larger, and another the Bender & Robinson exhibit on the Singer, this body being very low, as indicated in the drawing. It can be opened (permanent roof fashion) and the roof is entirely of glass, to enable the occupants to get light from above. This job was the most extreme design at the show, it was finished in good taste, both outside and in, and the right balance altogether gave the body a racy, but not an overdone appearance; for its class it hit the mark and did not shoot beyond.

Figs. 14 and 15 are two drawings of the Fleetwood Metal Body Co. cabriolet on the Lancia. Fig. 14 is the complete design and Fig. 15 shows the operation of folding the top down. The cabriolet is coming into its own as a town car, and while it will never be generally used, it has a class that appeals to the discriminating. This body is painted in yellow, red and black, the top is leather and the trimming light cloth, while the driving seat is black leather. The Barker cabriolet is operated in practically the same way as the diagram for the Fleetwood, but the leather quarter is cut semi-circular to allow the leather to part at the front when the top is thrown back, while the Fleetwood uses a loose flap that is fastened, when up, by glove fasteners. Barker had two cabriolets, one large and one small and both on Rolls Royce chassis. Fleetwood had a touring body on the Lancia that attracted attention on account of painting, this being a green color in which the brush marks are plainly left just as the paint had been spread. The makers use a special





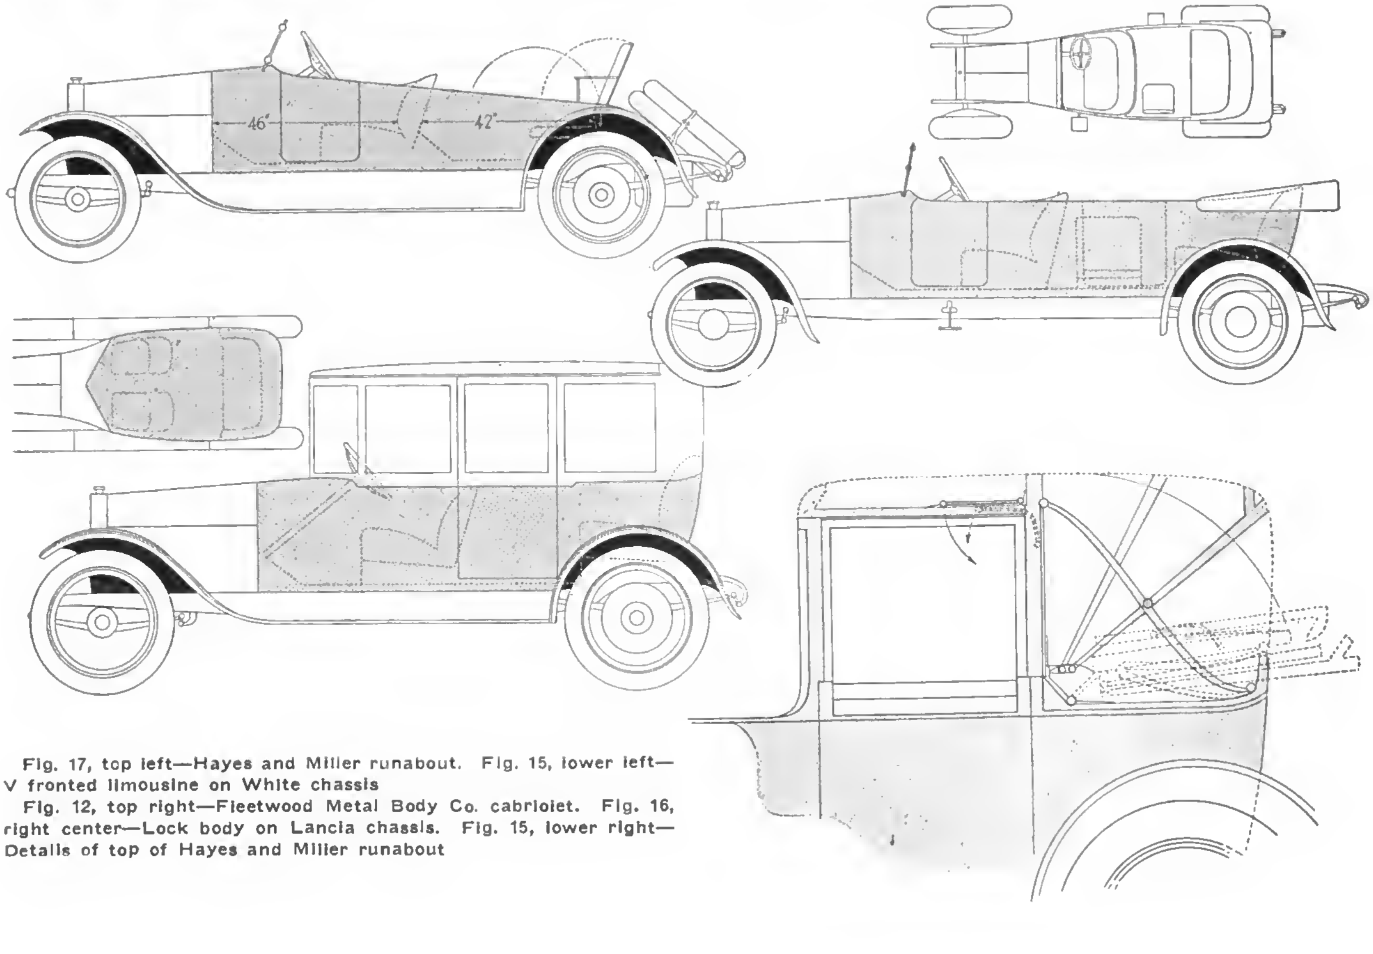


Fig. 17, top left—Hayes and Miller runabout. Fig. 15, lower left—V fronted limousine on White chassis
Fig. 12, top right—Fleetwood Metal Body Co. cabriolet. Fig. 16, right center—Lock body on Lancia chassis. Fig. 15, lower right—Details of top of Hayes and Miller runabout

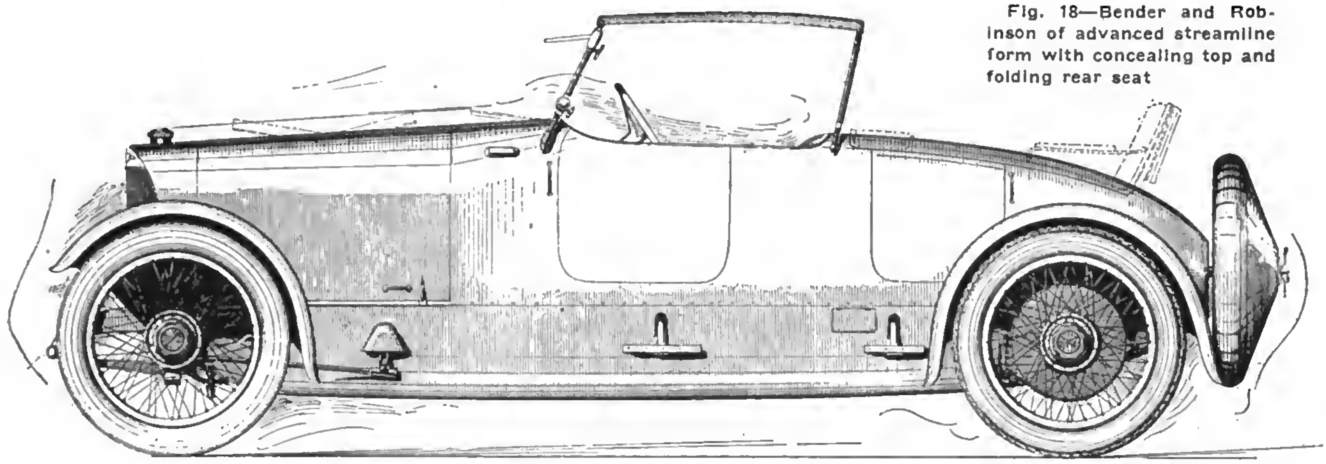

Fig. 18—Bender and Robinson of advanced streamline form with concealing top and folding rear seat

paint that does not need either dryers or varnish; it is applied with the brush and not rubbed smooth; in use, however, it wears smooth and gives the dull finish that has the most durable wearing qualities.

Fig. 16 is the outline of a Lock body on the Lancia. For five passengers, four on the seats facing forward and the fifth on the side seat placed practically on the floor, the occupant sitting across the car. This body came in for much favorable comment, on account of its light appearance and general air of tastefulness in finish and design. The doors are offset as indicated in the drawing, and there is no instrument board used; the clock and speedometer are placed at the rear of the driving seat and the other indicators on the dash board, this giving the cowl a very light and airy look compared with the majority of the bodies at the Palace show with their ponderous boards under the cowl. The paint was green and inside finish grey cloth, the top of the driving seat was especially good where it joined the side body line. Dome bicycle guards were used and steps in place of the running board.

Fig. 17 is the Hayes & Miller runabout on the Lancia, this job, while not absolutely new in design, being well received by the observing public and it merits all the favorable comment that was passed upon it.

Fig. 18 is another Bender & Robinson creation. It was tastefully painted and trimmed and was one of the few that approached a true streamline in its entire contour. It strongly resembles their larger body.

Good Patents Often Unworkable

By Walter Tibbetts

THERE is an erroneous impression held by a great many people, even among those who are otherwise well informed, that once a patent is issued to an inventor there is nothing whatever to prevent him from proceeding at once to manufacture the entire device or machine shown in the drawings of the patent. This probably comes by reason of the layman considering a patent as standing by itself, isolated, independent of all previous and future patents, a thing having no relation to anything that has gone before, a new creation made out of whole cloth.

On the contrary, it seldom happens that a patent is issued in these days but that the line between it and what is prior to it is so hazy as to require an expert in many cases to define it at all. And frequently a great deal of technical argument before the Patent Office is necessary to convince it that there is a line of demarkation in the case.

Every patent is so closely interwoven with the patents that have gone before it in the same art, that in most instances the device or machine of a newly issued patent cannot be made without infringing the claims of one or a dozen previous patents. In other words, practically all patents issuing from the Patent Office are "improvement patents;" that is, the devices and machines shown and claimed in them are simply improvements upon or changes in the devices or machines shown in previous patents.

Thus a man may invent a valve mechanism for a motor and, while his attorney will probably get an allowance of several claims that will not conflict with the various similar earlier patents to which his attention will be called by the Patent Office, yet it does not follow that his motor is not an infringement upon any of those earlier patents.

This valve mechanism may be arranged in the head of the motor and co-operate peculiarly therewith, which fact may give it novelty and make it patentable, but he will probably find several earlier patents on similar valves arranged at the side of the motor or elsewhere and containing claims that are broad enough to cover that particular valve construction regardless of its location or co-operation with other parts of the motor.

And even should his valve mechanism be of such nature that it is absolutely new in toto, yet he could hardly build and operate his motor without infringing a number of patents on several of the other essential elements of the motor, such as the carbureter, the magneto, spark plugs, etc.

Of course it does not follow that suit would be brought under all of the patents which such a motor might infringe, or if brought, that they would all be upheld against him, but the fact remains that the new device or machine in nearly every case is simply a step in advance in the art, and is usually anticipated in part at least by some one or more of the clever inventors that have gone before, so that the earlier claims will be seen to cover and perhaps control the later structure.

Obviously each inventor has the like privilege of making his claims as broad as the prior art will permit so that he may also cover the next inventor who comes along with a slight improvement upon his device. He is then in a position to stop the later inventor from making the improved device, and the later man, if he obtains a patent upon his particular improvement, may exercise a like privilege as regards the making of that particular form of the device. Neither of these inventors can make the improved form of the device without the consent of the other.

Of course the earlier patent will expire first and the later inventor may then use everything shown in it, while the first

Condition and Development of the Automobile Industry in Russia

By Professor Nicolas Kouznetzoff,
of Petrograd

THE development of automobilism in Russia dates from the first automobile exhibition which took place in Petrograd in 1907. This was followed the next year by another exhibition in Moscow and the last show took place in Petrograd in 1913. This was of a specially great importance to the development of the automobile industry, and the number of cars imported into Russia during 1913 was doubled, being 2000 as compared with 400 the year previous. Every year the Imperial Russian Automobile Society organizes contests which are partly races and partly reliability trials, and these are of great benefit to the business, more particularly because they introduce automobiles to towns and cities where motor vehicles have never before been seen.

In 1909 an automobile regiment was organized in Petrograd, and this was the beginning of military motoring in Russia.

Prof. Nicolas Kouznetzoff

Five Cities Led Before War

Before the war commenced the automobile business was more or less concentrated in Petrograd, Moscow, Kiev, Riga, and Charkow, and the following table shows the approximate sales:

Petrogad	2,600	Riga	600
Moscow	2,200	Poland	1,500
Kiev	1,000	In other States	3,000
Charkov	800		
		Total	12,000

In this enumeration the military automobiles are not included and these probably numbered about 1500 at the outbreak of war.

German Cars Were Popular

Concerning the cars tabulated above the majority came from Germany. France ranked next and England had a fair proportion. A good many also came from Italy and a few from America, mainly Ford, Case and Hupmobile.

In the city of Petrograd the most popular car was the Benz, with the Opel ranking second, and then followed Renault, Delaunay-Belleville, Mercedes, Fiat, Metallurgique, Vauxhall, Itala, Rolls-Royce, Peugeot, Lancia, Panhard and a few less known French makes. A certain number of cars are also turned out at the Russian factory in Riga.

No Real Automobile Dealers

Trade conditions in the automobile business in Russia have been very unsatisfactory, owing to the absence of agents or dealers as understood in America. Many good firms were represented by people who regarded automobiles as a side line and the general poor state of affairs led to the establishment of manufacturers' depots in Russia during the two years previous to the war. Much of this activity was the result of German farsightedness, as may be shown by the example of the Benz company who opened a branch in the best part of Petrograd, adding repair shops. The rent for the building amounted to $12,000 a year and at the outbreak of war an excellent business was being done. The first year more than 400 cars were sold and large inducements were offered to the clients. Another branch was situated in Moscow and was also doing a very good business indeed.

Almost as good a trade was being done by the Renault branch in Petrograd although the sales were slightly smaller than those of the Benz. In 1914 Renault actually commenced to build a factory in Petrograd, intending to manufacture cars on the spot, but of course this is at present operating on the manufacture of munitions.

Among other well known manufacturers having depots in Petrograd may be mentioned Mercedes, Delahaye, Fiat, Metallurgique and Vauxhall.

American Car Prices Exorbitant

Concerning American cars in many instances the Petrograd agent represents several different manufacturers. For example, the Ford and White are handled by M. Fride, while Pluim & Oxs sell Cadillac, Hupmobile, National and Saxon. M. D. Mikailovsky & Co. have the Chandler and Metz. Case, Chevrolet, Detroiter, Franklin, and Mitchell have individual representation.

The sale of American cars in Russia has been restricted by the extravagant prices asked and by lack of proper advertising. A Ford car in Petrograd costs $1,187.50. Of this amount the freight and import duty amounts to about $300 in normal times, so it is easy to see that an extravagant profit is obtained somewhere. Another trouble is that many of the agents carry an entirely insufficient stock of spare parts and a man hesitates to buy a car knowing that a replacement may take from two to three months to obtain from America.

7500 Cars and Trucks Needed

Notwithstanding the unsatisfactory condition the Ford has sold extensively, the agent being credited with a turnover of more than 1000 cars per year. It can be stated positively that during the first year after the war Russia will need more than 6000 passenger cars and not less than 1500 trucks. After this it is expected that the annual demand will increase at the rate of 100 per cent each year.

Many people are unaware of the existence of the Russian-Baltic factory of Riga, which has been producing railroad cars and commenced the manufacture of automobiles in 1899. The factory has been favored by many large government orders and at the start of the war was building complete cars without the need for importing any parts. Its estimated output for the past few years is between 300 to 500 cars annually and its most recent program consisted of two models of passenger cars. Only experimental trucks have been built and the work of the factory must have been somewhat interfered with by its transference from Riga to the interior. At present, the entire output is taken by the government for war purposes.

No Large Car Builders in Russia

It is perhaps surprising that the number of cars used in Russia should be so small, but the situation is explained by the paucity of state roads and the unsatisfactory conditions of sale which have been described. It may also be due in part to the absence of any large automobile manufacturing plants in Russia. At present there are only 22,000 miles of state roads in all Russia. They are situated mostly in places where they have a military value such as the western part of Russia, in Poland, in the Caucasus and in the state of Moscow. In addition to these principal state roads there are country roads aggregating about 135,000 miles, and these are quite satisfactory in summer. In the spring and fall the majority of the roads are impassable, although all-year traffic is possible on a few. The reason for the roads being so bad is that the money available for their improvement has been insufficient. It has absorbed the attention of the government to develop the railroads, but the Duma has been devoting attention to roads recently and it is expected that the state road system will be extended very greatly soon after the war.

Less Than $5,000,000 Yearly for Roads

At present, for building new state roads and repairing old roads there is an annual appropriation of less than $5,000,000 and two-thirds of this is given to the roads having military importance. This, of course, leaves but a small sum when one regards the vastness of the road system really required by Russia. As a comparison, it is interesting to observe that the State of New York last year voted nearly three times as much money to roads as does the whole of Russia in a normal year.

The use of automobiles in the war will undoubtedly result in their value being appreciated much more widely and there is, therefore, every reason to anticipate that the building of new state roads will proceed very rapidly when the war is over. The ministry of ways of communications has already worked out a scheme for a complete system of state roads interconnecting with new railroad lines.

Cars Taken for Army

Harking back to the start of the war, one of the first problems of mobilization was the necessity of equipping the army with a proper quantity of automobiles. The first step taken was to issue an order appropriating all private cars and almost every one of these in addition to every truck was taken for the use of the army. In this manner about 3000 passenger cars were collected. The majority of firms which used trucks for handling their product were left entirely without means of transportation.

America Has Contracts

In addition to this appropriation of all trucks in the country the Russian war department sent a special commission to London and there purchased all the trucks it could get at that time, also ordering some American cars and motorcycles through the London agents. The European supply was soon exhausted and at present America is the only country holding war contracts for motor vehicles for Russia. The largest American orders have been given to White, Packard, Pierce-Arrow, Peerless, Locomobile, Jeffery, Garford and Federal.

Large Market Expected After War

At the end of the war there will be a very large market for motor trucks in Russia. In the last two years trucks have been used to an increasing extent in the principal cities. The types mostly desired for Russian use are 5- or 6-ton trucks which are required for city service and light trucks of from 1½- to 3-ton capacity for the country. It seems reasonable to assume that Russia will look to America as the principal supply of automobiles and there is no doubt that America can grasp this great market if it will only act quickly. After the war German competition will be renewed and will be extremely keen so it is necessary that the American manufacturers should make a concerted effort properly to establish themselves in Russia.

American Cars Popular in Russia

The matter to which the American industry needs to give the closest attention is that of securing proper sales representation and it is the opinion of the writer that success can only be hoped for by means of establishing American-owned and managed sales and repair establishments throughout Russia. At present American cars are popular in Russia because they are better able to withstand bad roads. Plans should be proceeded with immediately, since now is the time to establish the American industry in Russia. There is much to be lost and nothing to be gained by waiting until the war is over.

A Truck-Factory Opportunity

Another great opportunity for American industry is to erect a truck factory in Russia itself. Shortly before the war French, German, and some British automobile manufacturers were planning to build factories near Petrograd or Moscow, and there is no doubt these intentions will be carried out. An American concern intending to manufacture in Russia would be able to commence operations immediately. Of course it is a truck factory which is most urgently needed. A law is expected to be passed which will subsidize automobile trucks modeled on the German system which will encourage the purchase and the use of trucks. It is obvious that those who are first in solving the problem of giving Russia an adequate supply of commercial vehicles will obtain the largest orders at the earliest moment after the war is over.

Let it again be said that the opportunity is at its best just now, to wait for another year in order to see how things are going is to lose a substantial amount of advantage when the big orders come along.

A graphic illustration of the area of Russia in Europe as compared with the United States and giving an idea of the possible automobile and motor truck market which it is expected will be opened to American manufacturers at the close of the European war. In addition, it must be remembered that Russia in Asia represents a much larger territory than that illustrated, although there is a comparatively small population

Electric Efficiency Improved

Better Engineering Keynote of 1916 Electric Passenger Cars—Lower Weight and Improved Electrical Parts Give More Miles per Charge

THE keynote of progress in the electric passenger vehicle field during 1915 has undoubtedly been better engineering as indicated in the many refining touches, greater standardization and factory economies in production, all of these making possible considerable price reduction in nearly every case.

It has not been easy for the manufacturers of a product, heretofore regarded as a thing to be marketed only in comparatively small quantities to a leisure class and to the feminine element, to cut production cost without in any way curtailing quality. In most manufacturing activities it is the rule that unless quantity of output is greatly increased it is impossible to lower price without sacrificing the qualitiese for which the electric must always stand. But it has been done, and by the strictest attention to design the new models are in every case better. It has meant much for one of the leading makers to bring down prices averaging $700 on all models, and for another to lower them $150 to $200 per car, but they are signs of the times. They have materially increased their outputs, in one or two cases actually doubling their manufacturing schedules.

Weight Cut in Many Cases

Weights have been lowered in many instances, models almost alike but heretofore differing in only a few details have been standardized so as to use the same chassis wherever possible, batteries have been lessened in weight at the same time that they have been increased in capacity, motors have been improved so as to draw less current, and these latter influences have had their effect upon the greater mileage of the cars per charge. The need of absolute silence has been still further recognized, and all have come to some form of silent axle gearing—in most cases either spiral-bevel or a worm gear type. Speed has been increased so that many cars will now attain a maximum of 30 m.p.h., which is more than ever needed within the city limits, although a feature of advantage for suburban going. The need of lubrication attention has been minimized as well as care of batteries, these being factors which cannot help but appeal. In short, much has been accomplished in a few months, and the electric industry to-day is on a better basis for success than ever before.

Few Startling Changes

Thus while no sweeping changes have been made by anyone, a better all-around vehicle has been evolved as a result of the general refining process that has manifested itself, not in any one part of the chassis only, but here and there throughout the whole car. In a few instances a large part such as an axle or a type of motor has given way to a different construction, but this is rather the exception than the rule. Most of the changes have been of a refining nature.

A more general use of aluminum for the body panels and fenders has been the rule, and this has had its effect upon lightening the cars. Another factor for lightness has been quite a wide adoption of stampings and forgings to take the place of castings, one of the leading makers effecting a considerable saving in this way, while at the same time strength is increased. In making such a change as this, however, much depends upon the facilities of the factory and the volume of the output, for it would obviously be impossible to go to the great expense of making dies for forgings and stampings unless the quantity of the output would warrant it. Here again is an instance of the advantage of larger output, for once the preliminaries are over, it costs less to use forgings and stamped parts than castings and they are more desirable.

Batteries Are Lighter

Another point of attack has been the battery, and in a number of cases weight has been lessened by redesigning the cells. One prominent maker has succeeded in cutting 50 lb. from the weight of the battery and at the same time the capacity has been increased. On the whole there has been little change in the mileage possibilities of the cars, many of them having been for a year or more capable of close to 100 miles on a charge, and this seems to be all that could be desired.

Of all types of vehicles on the market, the electric must be the acme of silence, and one of the points at which much attention must be focussed in order to bring this about is the rear axle. Since the spiral-bevel type of gearing has become so extensively used with such great success the worm-driven axle which has enjoyed high esteem among the electric designers, has encountered a serious competitor, and the list of designs of electric cars now on the market are now about evenly divided between the two types of final drive. One of the largest producers has come to the spiral-bevel within the past year, although still offering the overhead worm optionally. There are many designers who do not take kindly to the worm drive where they can get something else that equals it in the matter of silence. There is one big advantage of the worm however, that must not be overlooked, this being the fact that it gives a bigger reduction between motor and driving wheels than is possible with a single-reduction spiral-bevel axle. This means that the motor may run faster for a given speed of the car, and it can as a rule be smaller. However, so far as this point is concerned, and considering the current consumption, the advantages of one drive about offset those of the other.

As between the underneath and overhead worm types, there are about as many adherents of one as the other. Better oiling of worm and wheel is claimed where the worm is below, but such construction obviously reduces the road clearance and puts the drive shaft at a greater angle to the horizontal. Either of these may or may not be objections. In most of the designs using the underneath worm there seems ample clearance for average city work, and in fact any reasonable road surface, and there is no difficulty in attaining a straight line drive between motor armature and worm, it being simply a matter of supporting the motor at an angle to correspond. Adherents to the overhead worm have obviously overcome any oiling difficulties that may have been present in the earlier types, so that the position of the worm simply resolves itself into a consideration of which lends itself best to any particular chassis installation. Generally speaking, it would seem that the overhead worm type would lend itself to simplest installation, although this remark will not apply to every case.

Lubrication Improved

One refinement that is of special advantage to the car owner is the method of lubrication. There is a more general use of self-lubricating bushings, these doing away with a multiplicity of oil or grease cups. In thus reducing the number of parts demanding lubrication attention the cars have taken a decided step forward, for with the electric perhaps more than with the gasoline car the owner is less in touch with the mechanism, relying more on the garageman, and a reduction of the points for lubrication has an obvious advantage from this standpoint alone. This attention to grease cup reduction is more especially to be found in the steering mechanism, and this is a factor for greater safety since it allows of less attention to these parts without detrimental result. At points where grease cups have been applied, there is a tendency to make them more accessible, and in more than one design there is not a single grease cup beneath the car.

Turning to less mechanical aspects of the electric of to-day, it is at once noticeable that designs are being brought out which are more masculine in their appeal. Heretofore the electric makers have almost overlooked the fact that while their product is especially desirable to meet the transportation needs of the lady, it also can be made to fill a very important place with the business or professional man. Being dependable at all times, and usually equipped with solid tires, it can be relied upon to get the business man to his destination without delay, and can wend its way in and out of traffic with the least trouble in starting and stopping. Now that speeds as high as 30 m.p.h. and over are attainable, the manufacturers have awakened to the possibilities of selling mannish roadsters to the city man. Hence a large number of these have appeared and are meeting a popular demand that might well be increased with aggressive attack upon this hitherto neglected class of possible buyers.

Cars Have Better Bodies

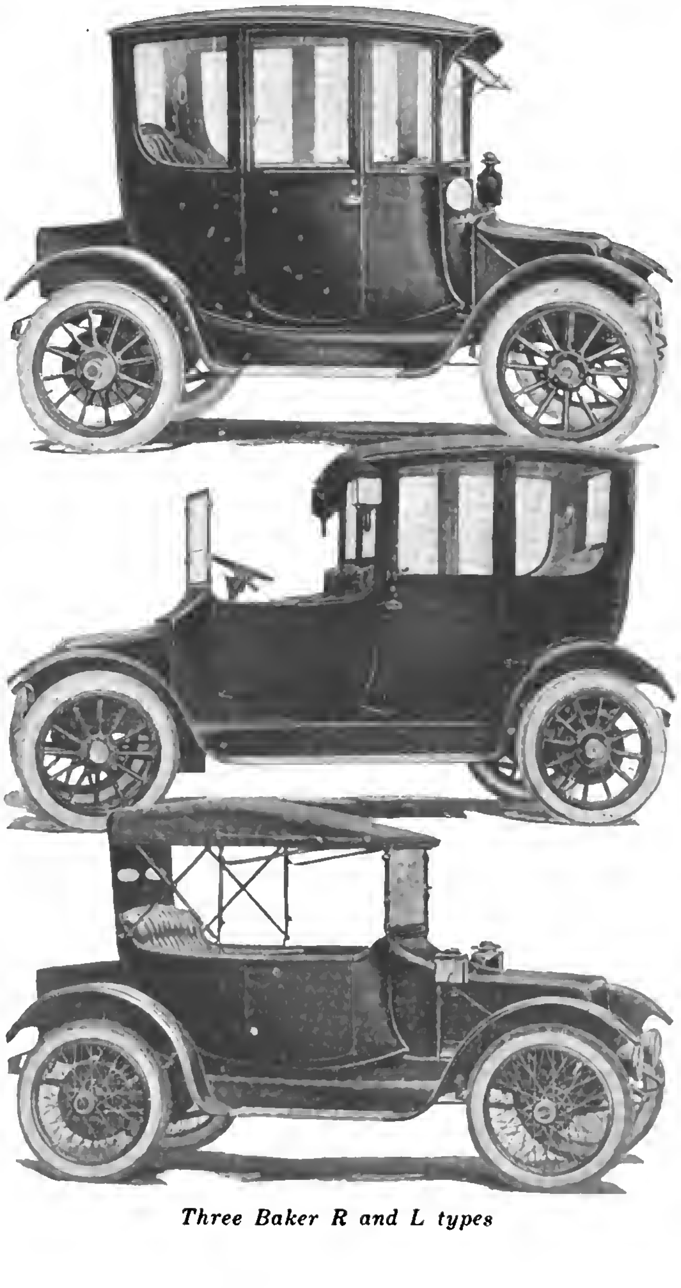
Externally the cars are even better to look upon. The impression is given by the new designs that the fenders, running boards, battery hoods and bodies are more of a unit, this being gained by the better and more substantial mounting of all parts. The domed fenders which seem to be consistent with the general curved lines of the bodies are attached much more rigidly than they used to be, and they have larger skirts to help in this direction. With the extensive use of aluminum panels, it has been possible to make the battery hood sides of the same sheets that form the body also, since it is possible to handle the large sheets of this material satisfactorily when hammering them to the proper shape, and for other reasons of unity, substantialness and appearance. In most cases, the corners have been very pleasingly rounded and the hoods blend into the bodies to prevent any suggestion of a break between them.

There is little to be said regarding the interior appointments. It is difficult to imagine more elegance in upholstering, interior finish or fittings than the average electric possesses and aside from some rearrangement of the seats, better upholstery and more comfortable angle to seat backs in certain instances, there is little alteration over the designs of the previous year. If there are any discrepancies in the modern electric vehicle, they are most certainly not to be found in the interior finishing or fitments.

To give more capacity to batteries, there are several instances where this has been done by adding plates to the cells rather than by increasing the number of cells. At the same time motor efficiency has been improved so that in general the cars operate to a greater distance on a charge, if there has been any change in this respect, due to a combination of greater battery power and less current draw by the motors.

Realizing the need of better maintenance facilities in order to increase the use of electrics and breed satisfaction among present users, there has been a widespread movement among the electric men during the past year to afford better service along with cheaper rates for charging. This tendency was boosted by the opening during last summer of the new co-operative electric garage of the New York Electric Vehicle Association. This is now housing its full quota of 100 cars, and the equipment of this station, which is the largest in the Metropolis, is unusually complete, having facilities for charging from 100 to 200 cars per day and to care for the various sizes and types of batteries. With this as a germ, finely equipped electric garages are springing up in greater numbers all over the country, and in some instances going even farther and give a free parking service during the daytime. In Chicago this feature is of greatest value for in the congested Loop district it would be almost impossible to use the cars intermittently without some place to put them temporarily when at the theater, shopping, etc.

In the matter of battery rental much has been done within the year with the Walker Vehicle Co., the pioneer. Now



Three Baker R and L types

operative only in Chicago, this scheme has proven successful, and it consists mainly of selling the car without battery if desired, the car owner renting a charged battery for a certain amount monthly. Other private garages have taken it up, and the industry as a whole is very much interested in the plan. We may expect to see it materially increased in its scope and adoption within another year.

Detroits Refined and Cheaper

Although many minor mechanical changes and little improvements in the bodies of the Detroit Electrics make them better cars than those they succeed, the feature of the Anderson Electric Car Co.'s activity at this time is the large price reduction of all models which is made possible by a practically doubled production as compared with one year ago. The Detroits now sell at prices ranging from $1,975 to $2,275, which means reductions running from $600 to $725, depending upon the model.

The 1916 Detroit list includes six body types:

Model 61, four-passenger brougham, price reduced from $2,600 to $1,975.

Model 60, five-passenger double-drive brougham, lowered from $3,000 to $2,275.

Model 59, rear drive, five-passenger brougham, price lowered from $2,950 to $2,225.

Model 58, front drive, five-passenger brougham, lowered from $2,950 to $2,250.

Model 57, four-passenger inclosed type, cut from $2,850 to $2,175.

Model 56, three-passenger cabriolet, $2,650 formerly and now $2,075.

There is nothing changed in the basic construction of any of these models, as they continue to use a 4-hp. series-wound motor with shaft drive to the rear axle, and a forty-two-cell lead battery equipment. For the rear axle there is an option of either the standard type of worm drive used in 1915, or a floating spiral-bevel rear unit with a reduction of 6 to 1. There are, however, a number of refinements that tend toward great interchangeability of parts throughout the line of bodies, and to even better body work, performance and convenience.

Among the mechanical details that have been improved is the redesigning of the current cut out in order to adopt the more efficient knife-blade type of switch. The box containing the cutout has a removable cover for inspection purposes. Besides this, the taking out of two screws allows the removal of the bottom of the box, to which the contacts are fastened. Thus the container of this important unit has increased accessibility, is simplified and greater proof against wear.

As a factor for reducing the weight of the cars in many points throughout the chassis, castings have been replaced by stamping and forgings, these also increasing the strength. Weight has also been cut from the battery to the extent of about 50 lb., this despite the increase in capacity. Another point of weight reduction is in the rear axle, and the sum total of all this better designing is a chassis which is 150 lb. lighter than its predecessor. Refinement has also been brought about in the brakes which now have one-piece shoes lined with a better braking material, this resulting in not only more positive action but also in increased life of the lining. The new chassis also shows a more general use of self-lubricating bushings and a reduction of the number of parts requiring lubrication attention. Looking to greater conservation of power the wiring has been rearranged to give a shorter distance for the current to travel, hence less voltage loss.

Wherever it has seemed possible to do so the seats have been made more comfortable, this particularly applying to the Model 57 whose rear seat is deeper and which has a new and more comfortable arm-rest. Doors in this model have also been widened.

Woods

Waverley

Ohio

Baker, Rauch & Lang Prices Lowered

Nine models are listed by the Baker, R. & L. Co., and although none of these is totally new, each is an amplification or improvement upon its predecessor. They chiefly differ in that they have a higher-speed motor, a larger motor brake and a number of minor improvements that help to produce greater ease of operation and greater comfort. Price reductions have been made on some models. The roadster and the club roadster remain at $2,600 and $2,800 respectively, but the brougham is $150 lower at $2,800. The coach and Baker brougham both now sell at $3,000 instead of $3,200. For this season the Baker car will be confined to this brougham known as BBD 6 which is a double drive model and to the DA 6 coupé which sells at $2,475. The other models will carry the Rauch and Lang name.

Mechanically there has been few changes except those which another year's experience dictate. The battery equipment in all models remains the same and is eleven MV Hy-Cap Exide, forty-two cells in the larger cars and forty-one cells in the lighter types with the exception of the Baker coupé with thirty-six cells. Mileage per charge has not been

Hupp-Yeats worm drive type

Chicago 5 Passenger

Ward Coupé

altered and Baker calculated this to be from 50 to 85 miles according to conditions and the driver. Mainly the aim has been to still further promote ease of control, freedom from adjustments and safety. These cars use a worm drive rear axle which is said to have proved exceedingly satisfactory after long service. Silence is especially the result of this axle combined with the light-weight, high-speed motor.

A shorter turning radius has been secured by narrowing the chassis at the front end. There are four different wheel bases to conform to the different body types. The two town car models have 109-in. wheelbase, the roadster types and two of the broughams are 92 in., the coach and the Baker brougham 102, and the Baker coupé 90 in.

On the Rauch & Lang models an ampere hour meter has been added as the central feature around which is grouped the ammeter, voltmeter and the speedometer. These accessories have been well located in a unit with sufficient illumination to make them readable under all circumstances.

Altogether the changes make for convenience, and for the comfort of the driver.

Waverley Concentrates on One Model

A policy of concentration upon one model has been decided upon by the Waverley company. This is designated as Model 110 and takes the place of all previous Waverley types. This car is entirely new throughout, both in body construction and body features. Briefly the specifications of the new chassis include forty-two cells of eleven-plate lead battery of either Exide or other standard make, series-wound motor which drives through an open shaft to a spiral-bevel type of rear axle, with Hotchkiss drive principle employed. The wheel base is 95 in., with tire equipment 32 by 4 in. pneumatics or 34 by 2½ in. cushions.

It is a point of special note that the weight of this car is fully 1000 lb. less than that of any of the 1915 Waverley models, thus indicating the engineering refinement which the new chassis has undergone. To make maintenance as simple as possible spring lubrication is through self-oiling bushings without grease cups underneath the car.

The speed and mileage are practically the same as last year, the improvements in the engineering features being chiefly in the production of a light-weight model, while still preserving the roominess of a four-passenger car. The reduction in weight and the greater simplicity of the construction have made it possible to reduce the price to $2,150 when the body has an offset rear seat, and $2,200 where it is fitted with four separate chairs. The former seating arrangement accommodates three people on the rear seat and one on the forward seat. The body has metal panels and rounded corners with sashless windows and automatic window lifts.

A mechanical change is the mounting of the body on a pressed steel frame, this differing from the previous construction in which the mechanical parts were attached direct to the body. Long three-quarter elliptic rear springs are used. To make for safety of operation of the car, the new drum type of controller has an interlocking shift at the top of the controller core.

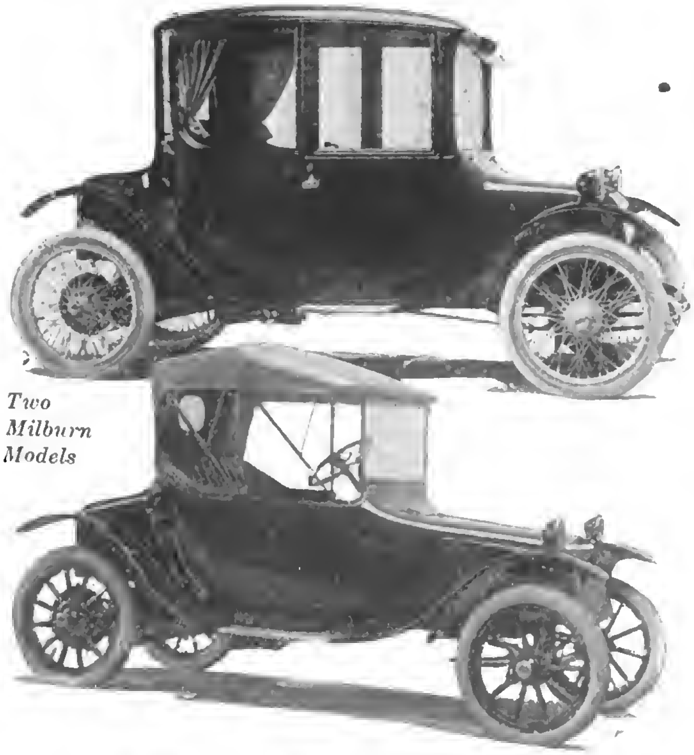
Ohio Continues Practically Same Models

There is nothing radically new in the 1916 Ohio cars, product of the Ohio Electric Car Co. The concern is continuing practically the same models as it was building last year with only those refinements which another year's experience in manufacturing makes possible. The Ohio special magnetic control is retained just as it was, having been a feature of cars of this make for several seasons.

For those who desire a large five-passenger car Ohio still builds its double-drive brougham Model 62 at $3,250. The other prominent models are a single-drive brougham, Model 42 which accommodates five and sells for $2,900; and a four passenger coupé, Model 12, $2,400.

The Ohio company was a pioneer in the double-drive type of car and brought out its first models with this feature in 1912. In its construction there are two separate sets of controller mechanism, one in front and another at the rear seat, either operating the car independently of the other. The controller itself is of distinctive design with the different speeds attained by turning a compact hard rubber disk at the side of the small controller head. Steering is by the conventional lever. Four forward speeds and three reverse, the magnetic brake and the warning signal are all operated from this controller head.

Standard battery equipment in all models is the same as it was with the Model 42 brougham having forty-two cells and the double-drive car forty-four. The speed of all the models has been increased so as to give any desired speed up to 28 m.p.h. at a maximum. A very ingenious feature of the transmission unit is the supporting of the torsion tube between the motor and the rear axle at a point very near to the center of inertia, with the idea of putting all the weight of



Two Milburn Models

Broc

these members on the frame and above the springs so that they are sprung weight, thus effecting a saving in tires and reducing the required power while at the same time a greater factor of safety results.

Ohio coach work is exceedingly well carried out and the various parts such as battery compartments and fenders seem to have a pleasing unity with the body itself. The bodies are all of aluminum as well as the fenders which are hand hammered. As an example of body refinement, the hinges are concealed and there is an absence of moldings which is made possible by shaping the entire body as a single panel instead of joining the various sections together as in the past; thus following gasoline practice.

Argo, Borland and Broc Unchanged

The American Electric Car Co., continues its three types of electrics known as the Argo, Borland and Broc. Under each of the three names, three models are listed. The Argos are a forward-drive brougham at $2,800, a rear-drive brougham at $2,650, and a rear-drive roadster at $2,350. All three chassis are the same excepting that the forward-drive brougham has a slightly longer wheelbase than the other two. Forty cells of eleven-plate Exide battery are furnished with either car, this supplying a Westinghouse series-wound motor located on the rear axle and driving through a combination of double reduction herring bone and bevel gears.

The Borland models are not the same as the Argo types, the most important difference being in the use of a double-reduction by a silent chain to the propeller shaft and bevel gears in the rear axle. All three Borland chassis are the same except the wheelbase on the forward-drive limousine, seating seven and selling for $5,500, is 123 in. in length, whereas the other two models are 96 in. There is a rear- or forward-drive coupé for five at $2,550, and a two-passenger roadster at $2,250. Steering is by wheel except on the coupé which has a lever.

The limousine forward drive model is equipped with forty-two cells of eleven-plate Exide battery with a complete installation at the front. The roadster has forty-two cells of eleven-plate type equally divided between front and rear, and in the coupé there are forty cells. In these models a G. E. series-wound motor is used and both sets of brakes are operated by pedals and act upon the rear wheel drums.

It is in the Broc models that the greatest standardization appears as all three are broughams on a standard 96-in. chassis. These models are a rear-drive at $3,100, which seats five, a double-drive also for five at $3,200, and a four-passenger, front-drive type at $3,150. The drive system is somewhat similar to the Argo, with the motor a series-wound Westinghouse hung centrally in the chassis, whence it drives by a shaft to a double-reduction combination bevel and spur gear floating axle. In all three the battery equipment consists of forty cells eleven-plate Exide. Braking is quite different from the Argo and Borland cars, in that one set is on the drive shaft and operated by lever, and the pedal set acts upon the rear wheel drums.

Milburn Adds a Brougham

Besides continuing its Model 15 chassis with roadster and coupé bodies the Milburn Wagon Co., which though long in the vehicle manufacturing business entered the electric vehicle industry a little over a year ago, is offering a brougham at $1,585 on a new Model 22 chassis. The continued models have been unchanged in construction and sell for $1,285 as a roadster and $1,485 as a coupé. Comparing the new chassis with the earlier design, the chief differences are in the wheelbase, which for Model 22 is 105 in., and for Model 15, 100 in., in the battery equipment which for the new chassis has two more cells than the older type, and the tire equipment which is 32 by 3½ in. as compared with 30 by 3½ in. on the Model 15. The new car has twenty-two cells of seventeen-plate W.T.X.I. type, whereas the other model has twenty cells, fifteen-plate W.T.X.

In these cars which have as their chief features comparatively light weight and low cost simplicity is especially apparent throughout. New to electric construction previous to being taken up by Milburn, is the cantilever spring suspension used both front and rear on the Model 15, and in the rear only on the newer car. G. E. motors are used, and the drive shaft is inclosed within a torsion tube and is very short due to the location of the motor considerably back of the center of the car.

An excellent straight-line drive is had by mounting the motor at the same angle as the shaft, which terminates in an underneath worm-drive axle with a direct gear ratio of 9.75 to 1.

Body work is excellent and reflects the long experience of the Milburn concern in the vehicle business. The battery compartments front and rear are made with the same panels that form the sides of the body proper, and there is an unbroken curve between them. Sashless windows are employed, and fenders are crowned and well fitted. Wheel steer is used on the roadster, but the inclosed cars have the usual handles.

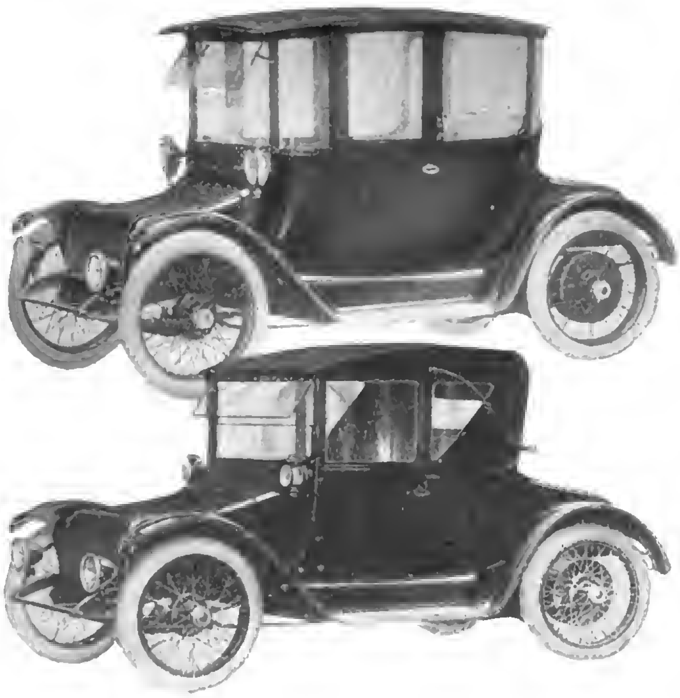
The new model is capable of slightly higher speed than Model 15, due to its larger battery and motor. On the third notch, Model 22 attains 18 m.p.h., whereas Model 15 gives 16¼ m.p.h. Treads are 50 in. for Model 15 and 52 for Model 22.

Ward Coupé a New Design

Quantity output has made it possible for the Ward Motor Vehicle Co., to market an entirely new coupé at $1,295, which is the lowest priced car of the kind on the market. The one model constitutes the line, and it supersedes the coupé which last year sold at $2,100. An unusual feature is that the entire forty-two cell, nine-plate lead battery is placed under the front hood, giving the car somewhat the appearance of a gasoline type. With this novel body arrangement, four to five passengers can be accommodated on the wheelbase of 88 in. The body length, glass to glass, is 74 in.

The car has a conservative mileage rating of from 35 to 45 miles, attaining a speed ranging from 12 to 15 m.p.h. From the motor, the power is transferred through a single propeller shaft to a spiral-bevel rear axle. A pressed steel frame is used, and spring suspension is by semi-elliptics front and rear. Tires are 33 by 4 pneumatic on demountable rims.

The body construction is attractively worked out so that the same panels of hammered metal that form the sides also integrally include the battery compartment. Interior finish, includes plate glass windows, grey silk curtains to match the grey upholstery. At the price, the equipment includes such items as odometer, locks for the doors, chargometer, thermometer, electric horn, and tools.



Two Detroit Models

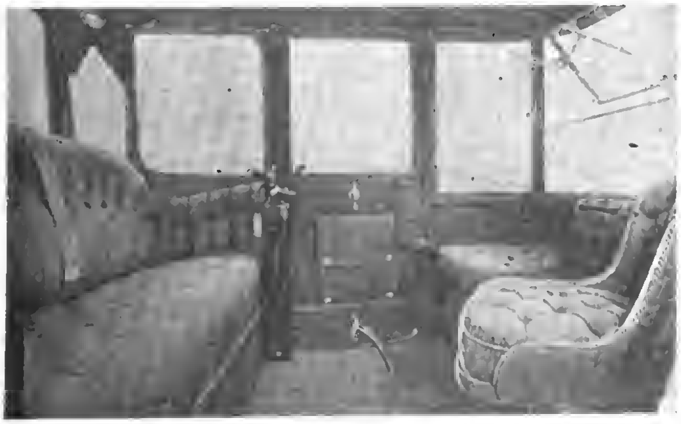
Two New Chicago Models

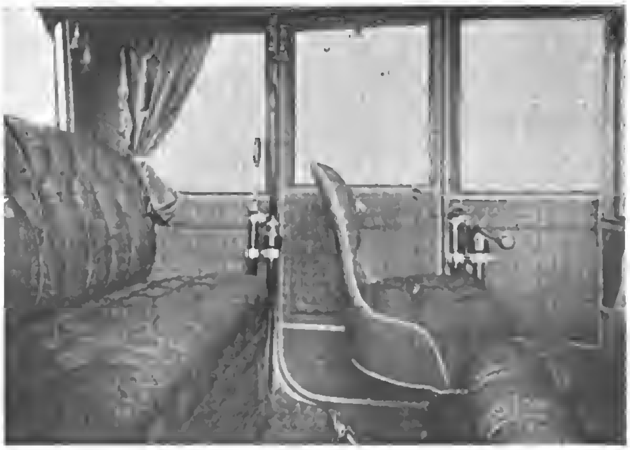
Two new models, termed the Edison models, are now on the market as Chicago electrics, made by the Walker Vehicle Co. These are designated as Models 162 and 163, and they are equipped with Edison battery as standard. They also carry the new Chicago body design which is representative of the latest ideas in electric car construction, and although built along conventional lines, it is low hung and has a long effect. All angles and sharp corners have given way to graceful curves. The arched doors have been modified, as compared with previous Chicago types, to give a straight line roof with only a slight arch perceptible over the door.

Many structural improvements have been added, these particularly with a view to the use of solid tires, for it has been found that more strength than ordinary carriage building affords is necessary in the electric car when solids are used. Aluminum also plays an important part, as it is employed for all parts exposed to the weather.

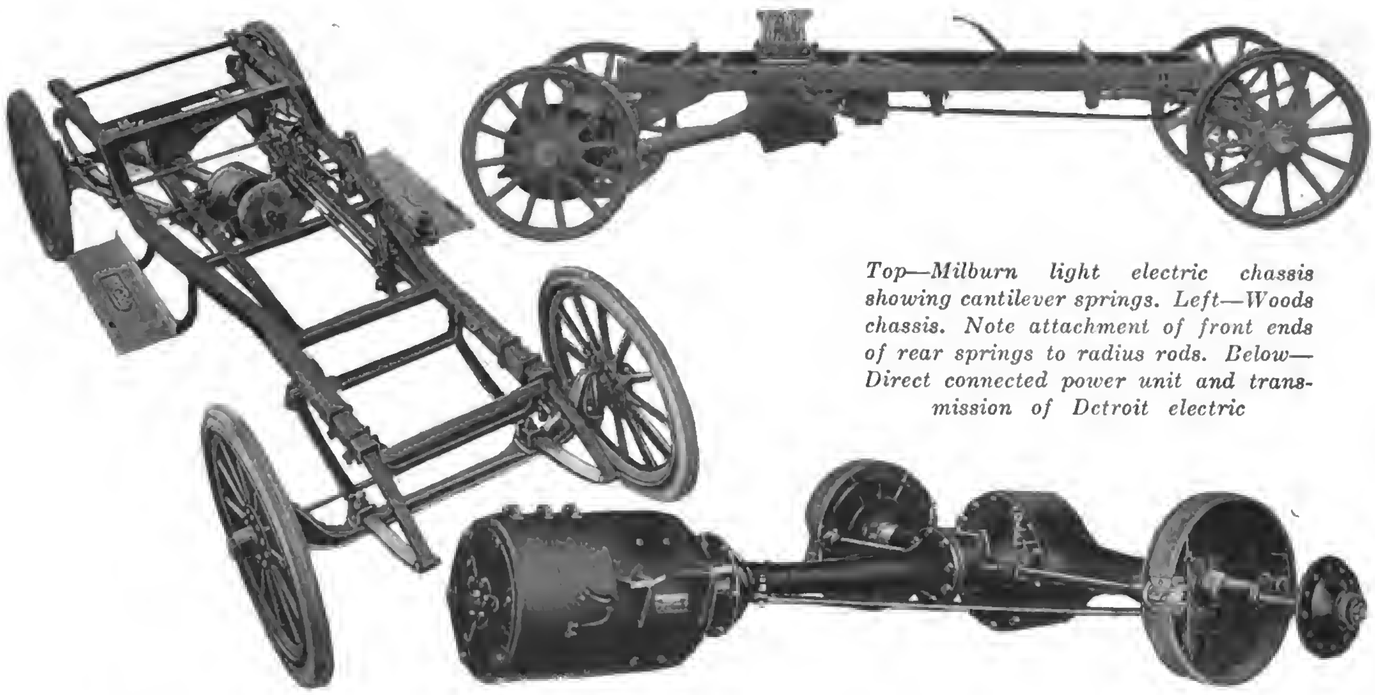
To long running boards are attached the new crowned fenders which are fully skirted to the bodies. Improvement has been made in the window lifting mechanism for operating the sashless glass, and by different positioning of the revolving seats they are made more comfortable and accessible.

Model 163 is a four-passenger rear seat drive car which has an emergency seat for a fifth, and it sells for $2,835 with a sixty-cell, G 7 Edison battery and $2,185 with lead battery. On this chassis, which has a wheelbase of 96 in., there is also built a cabriolet roadster body, and with the Edison battery equipment above mentioned it costs $2,535, as against $1,885 with lead battery. On the Model 162 chassis,





The great luxury of the interior of electric cars is well shown by these three views. The upper is of a Detroit electric, the center view a Waverley and that on the extreme right a Baker R. and L.



Top—Milburn light electric chassis showing cantilever springs. Left—Woods chassis. Note attachment of front ends of rear springs to radius rods. Below—Direct connected power unit and transmission of Detroit electric

with its wheelbase of 104 in., is fitted the new front seat drive, five-passenger limousine. As compared with the other bodies of the line, this averages 8 in. greater length and the seats are a trifle wider. The cost of this car with the Edison battery is $2,925, and with lead cells, $2,275.

The same general construction is followed in both chassis, and while building the frame into an extremely rigid unit to take care of the solid tires has been featured, careful study has also been centered upon proper distribution of the weight. Particular improvement is noted in the reduction of the necessary points of lubrication, especially the steering mechanism. Bronze bushings of long wear possibilities have been still more extensively employed than in previous models.

The motors are larger than previously and designed for heavier duty. They are the slow-speed, series-wound type and are coupled up with spiral-bevel rear axles, which were also used last year. The controller system consists of five forward and reverse speeds with brake operated by a horizontal control lever, this being a 10-in. contracting band acting on the propeller shaft.

The Walker concern is one of the pioneers in the adoption of a battery rental system for passenger electrics, and offers all purchasers in the city of Chicago, which is the only center in which it as yet has the scheme in operation, a reduction of $270 from the list prices when they elect to adopt this method of battery maintenance.

Woods Power Battery Increased

The 1916 series of Woods electrics, which are made by the Woods Motor Vehicle Co., are improved continuations of the models carried through last year with the exception of the Model 1524 which is a new car with a seating capacity for five and selling at $2,900. The leading model of the line, however, is Model 1522, which is practically the same as it was, and in general the body designs are similar to the 1916 types, but brought up to date in the matter of shape and appearance. Prices of these improved cars are the same as previously, Model 1522 being a four-passenger vehicle at $2,850, and having a wheelbase of 100 in., and in addition there are three other designs designated as 1501, 1503 and 1504. These latter all have a wheelbase of 110 in. and differ from one another mainly in the arrangement of the controlling levers, the first being a dual control at $3,100, the second a front control at $3,000, and the third a rear drive also selling for $3,000.

The Woods cars carry a battery which is specially made under the concern's own original design, and in increasing the battery power for 1916, the main change has been in the use of a greater number of plates per cell. Either chassis carries forty-two cells, and as a result of the plate change the mileage per charge is higher, the company giving the average as between 70 and 80 miles.

Much the same design is followed in both chassis, the frame being a special Woods feature in that it is narrowed at the front to allow a short turning radius. Like the battery, the motor is a special Woods design that is suspended in a subframe by means of a support on either side that has a ball and socket construction to allow free movement with the drive shaft. Located well back, the motor connects to the worm-driven rear axle with a short shaft that is inclosed within a torsion tube. Axle alignment is maintained by radius rods on either side. A special feature of the construction is the mounting of the rear springs upon the radius rods instead of on the rear axle. The radius rods extend from the subframe opposite the motor supports back to both ends of the rear axle at points just inside the brake drums and close to the center of wheel treads, and thus they act as a lever in relieving the rear springs of about one-third of the force of road vibrations, according to the designer. In the type of worm drive used, the worm is mounted under the wheel.

Hupp-Yeates Adopts Worm Drive

The only change in the chassis of the new Hupp-Yeates models as compared with those they supersede is the replacement of a bevel-drive axle for a worm drive. The Hupp-Yeates Electric Car Co., is now making three models, these being No. 3 Regent A which is reduced from $1,750 to $1,500, and the new models No. 4 Regent B at $1,750 and No. 5 Patrician which sells at $2,000. The first two are carried by the 86-inch wheelbase chassis and the last has a 100-inch wheelbase. But though the new cars round out the line, they follow the same general mechanical construction as the continued model with the exception that all three have the new worm axle that is furnished by the Cleveland Worm & Gear Co. It has a ratio of 8.6 to 1.

Model No. 5 is a four-passenger coupé with a thirty-six cell, eleven-plate Exide battery that supplies a 60-volt high-speed Westinghouse motor directly connected to the axle, the worm of which is under the wheel. Model No. 3 carries thirty-seven cells in its battery and also uses a Westinghouse motor, though it is smaller—48-volt. Thirty cells are employed by model No. 4, which has the same size of motor as the No. 5. On all models Goodrich Silvertown Cord tires are fitted, these being 33 by 4 in all cases except the front of Model No. 3 which is equipped with the 32 by 3½ size.

The interior of No. 3 is the same as the old model it replaces, it being upholstered in cloth instead of leather, however. No. 4 is finished in Bedford cord cloth with folding front seats and a split front window, and the arrangement and fittings of No. 5 are very much the same. This latter car is built with a very low appearance, due principally to the underslinging of the springs from the axles. It has a mileage capacity of 90 to 100 on a charge, it is claimed.

A feature of the Hupp-Yeates proposition is the furnishing as a part of the standard equipment of an electric battery charger, this being a Lincoln motor-generator type. Thus there is very little added expense attendant upon the charging of the car at the home garage, since it should not cost a great deal to have the charger installed. Hence any uncertainty as to the subsequent investment for car maintenance and charging is eliminated.

Hudson Crankshaft Eliminates Friction

Bending Couple Removed by Scientific Balancing—A New Idea in Balanced Engines

AUTOMOBILE engineers have been more or less curious to know how the Hudson company has been able, in its new six-cylinder motor, to obtain fully 80 per cent more horsepower than was delivered by the previous Hudson engine, which had exactly the same cylinder dimensions of 3½ by 5 in. Considerable mystery has shrouded the new design, and this curiosity was fostered by the fact that a patent on a principle involved in the engine was granted the Hudson company on Dec. 28, although the details upon which it was based were not divulged at the time the car was announced at the New York Automobile Show.

Aside from a careful and refined design along purely conventional lines, the patented feature and the secret lies in the counterbalanced crankshaft, the method of balancing being the really new thing. Careful attention to the working out of all details of valve passages, valve openings and carburetion, besides such other engineering considerations as design of the cams, timing and so on, have played their part in the increase of power which the Super-Six shows over its predecessor, and thus the ability of the new engine cannot rightfully be charged entirely to this new method of crankshaft balancing, although this is the one big factor.

Vibration Spells Power Loss

The reasoning on which the Hudson engineers have worked is that a great percentage of the power developed by a motor is absorbed internally in overcoming the forces which manifest themselves, these resulting in vibration and crankshaft distortion causing friction and loss of power. They realized that if they could reduce these wasteful forces to the minimum, the delivered power would be greater. This is really the germ of the present engine.

The new crankshaft is really not counterbalanced in the sense in which it is generally understood by the layman. The thing that has been done is to balance in a new way the forces present within the engine, this principle being what was patented. In order to understand the principle back of the design, it is necessary to follow through the reasoning which the designers used in determining the forces that had to be balanced at each point of the shaft.

First of all it should be said that the Hudson crankshaft is not balanced by having weights of equal size, shape and mass at each point of balancing, as would at first be expected. Reference to Fig. 1 will indicate the form of the weights used. There are in all three different forms of weights for different positions, and these are not forged integrally with the shaft, but are held in place by nickel steel bolts. The crankshaft is a four-bearing type, and at either side of each main and crank bearing there is a weight of some form. These weights are of a size and shape calculated to balance the inertia forces at the particular point at which each is located, and at any rotative speed of the shaft.

Weights Differ in Size

In proportion to the inertia forces present in a revolving shaft such as this, the unbalanced forces of the reciprocating parts are very small, hence these latter have been disregarded in the balancing of the more important and much greater forces due to inertia. Since these are of different magnitudes at each position along the shaft, the reason for the three different kinds of counterweights is apparent.

Referring to the diagrams in Fig. 2, the method of reasoning may be understood if we consider one one-half the length of the shaft, since the same conditions arise in the other half. In fact, the weights exactly correspond in their relative positions at either side of the center of the shaft. That is, the inertia forces with which we have to contend at a point three-quarters back from the front of the shaft are identical with those one-quarter back.

Suppose we consider then the forces acting on the first half of the shaft, which includes the first three throws. Each throw is in a plane at 120 deg. to the others, as indicated at *A*. The forces are considered all along the shaft from the first main bearing to the second, and in order to determine just what the inertia effect is at any point, it is necessary to determine the resultant inertia force that arises from the

Fig. 1—Hudson Super-Six crankshaft which is balanced on an entirely new principle

separate forces acting in each of the three planes. For instance, at Position 1, which is close to the front main bearing, the force acting in plane *X* is of a magnitude shown by the arrow in plane *X*, the amount of this force being calculated previously. Similarly, in plane *Y*, the magnitude of the inertia force acting in that direction is shown, and in plane *Z* it is shown in dotted lines. Now, referring to the vector diagram above at 1, these three forces are shown in their correct proportions and directions. From this, the resultant force *F* is determined by drawing the parallelograms of forces. At each position along the shaft the vector diagram is determined, and from it the resultant. In the chart the curve *M* is that of the forces acting at the different points in plane *X*, and *N* is the same for plane *Y*, as is *O* for plane *Z*. Referring to diagram *B*, we have plotted a curve of the resultant inertia forces acting at each point along the shaft between the two bearings, these being obtained in amount and direction from the individual vector diagrams already mentioned. This latter curve *E* indicates exactly the forces with which we have to contend at each position, and shows that the largest unbalanced force is at about the middle of the length between supports.

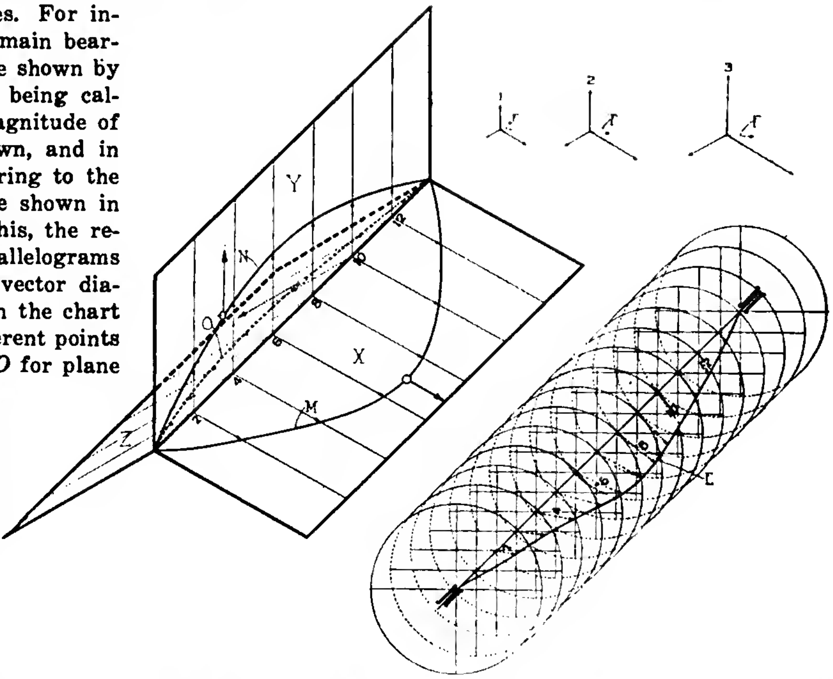


Fig. 2—Diagram of the forces acting on a six-cylinder crankshaft, for the purpose of explaining the action of the Hudson shaft which is balanced to eliminate inertia bearing pressures

Hence, knowing the values of these resultant forces at each point, the Hudson engineers set about to balance these by weights of proper size at each position. Obviously, to bring the shaft into exact theoretical balance, there should be a balancing weight at each point along the shaft, but this being physically impossible, the practical compromise is to put the weights of correct size and form where they would logically go, this at the webs of the crank throws. The principle involved makes it possible to get a correct running balance, within practical limitations, at any speed of the shaft, since the counterbalancing weights have increased inertia forces set up as the speed increases just as the natural inertia forces increase with the speed, and the two sets increase or diminish alike, thus maintaining running balance all the time.

Shaft Floats in Bearings

From this it will be apparent that the only function of the shaft itself is to form a practical mounting for the weights and rods, for, with the inertia forces balanced in this way, the shaft theoretically floats in its bearings when running, and thus in theory even a rubber shaft would be horizontal at all points when running, were it strong enough to take the power load.

It is interesting to note that the new Hudson shaft is very little larger than the previous plain shaft was, which shows that the matter of vibration has been attacked from the standpoint of inertia force balancing rather than stiffening to overcome vibration. Whether you stiffen a shaft or not, these inertia forces are still acting upon it and tend to increase friction and internal power absorption, so the logical thing to do is to compensate for them.

Of course, with these weighted throws, the crankshaft unit is heavier than that of the previous engine, although the better balancing makes possible a lighter flywheel. The new weighted shaft with flywheel weighs 164½ lb. whereas the old shaft weighs 120¼ lb.

In Fig. 3 is shown the power curve of the Super-Six engine, showing a maximum horsepower of 77 at about 2500 r.p.m., although the motor actually operates at close to 3000 r.p.m. as a maximum speed. When it is realized that at these high speeds the inertia forces amount up to several tons, the importance of this balancing becomes more apparent. Undoubtedly the Hudson engineers have attacked the problem of the eliminating of power-wasting factors at their source, and the results attained with the engine would seem to thoroughly justify the line of reasoning.

Automobile and Accessory Plants Help French Loan

PARIS, Dec. 23—Automobile factories have given considerable help in the raising of the $3,400,000,000 comprising the national loan just closed. Before the loan was announced, all the automobile factories made systematic collections of gold from their staffs, it being very difficult for men working eleven or twelve-hour shifts for six and one-half days a week to make a personal visit to the bank, in order to exchange gold for paper money. When the loan was announced the factories undertook to receive subscriptions toward it, and in very many cases to advance money to their workmen toward the purchase of stock. There was no limit to the amount men could subscribe for, and facilities were given for repayment by weekly instalments. Allowance was made for inability to make payments owing to illness, and if a workman left his employment before his stock had been redeemed, he was given the option of completing his payments or having all the deposits he had made refunded to him.

This scheme has proved very popular among automobile mechanics, most of whom are now earning good money and have been glad of the opportunity to invest profitably and safely.

The French staff of the Michelin Tire Co. has invested in this way a total of $1,010,060. As early as September, 1914, Michelin offered to loan money free of interest to any of his staff wishing to subscribe to the short-term treasury notes. In June, 1915, further loans were made to the staff toward the purchase of national defense bonds, and finally the total of more than $1,000,000 has been subscribed by the staffs in France toward the recently closed war loan. This year the shareholders in the Michelin company were paid in the national war loan stock, an innovation which was accepted with general approval. All Michelin employees totally disabled in the war are given an annual life pension of $190, this of course being in addition to the pension given by the State.

Italian Trade Profits By War

Factories Produce More Cars and Trucks Than Army Requires—Passenger Car Development Continuing

By W. F. Bradley

Paris correspondent of THE AUTOMOBILE, *recently returned from examining the busy and prosperous automobile and motor truck industry in Italy. The following is the second of a series of articles on the subject and reviews the passenger car field*

COMPARED with other European countries it has been possible to visit, Italy bears few external indications of a state of war. When the rigorous frontier formalities have been attended to, the visitor finds himself among a people, who have suffered neither the depression of an invasion nor the exhaustion of a long and undecided campaign. Alone among continental countries, Italy has imposed no restrictions on motoring, and with the exception of the frontier strip, puts no obstacle in the way of free movement of and a badge on the arm of many of the workmen and foremen indicates that they are under military restrictions. Such men, whether they be day laborers or skilled engineers, cannot leave their employment, cannot strike, cannot run short time, or absent themselves without leave. The organization throughout is remarkably efficient, and although the Italian automobile industry is not as important as that of some other European countries, the quality of the factories is certainly the best. Extensions are the order everywhere. There are very few factories in which building operations are not being carried out; this work is being done in a very systematic manner, and as the extensions are made with a view to increased output of the ordinary product, there is no confusion and no disorganization.

Labor Is Plentiful

There appears to be no scarcity of labor here. Women have not replaced men in any of the factories, and there has been no confusion by reason of the enlistment or the calling up of men necessary for the most efficient working of the shops. In all countries possessing compulsory military service precautions have to be taken against the shirker, who would prefer to do military duty in a factory, or some other safe post, rather than in the trenches. The Italians have got over this difficulty by making it a crime, punishable by a long term of imprisonment, without the option of a fine, for any employer to retain in the factories any man, who was not actually employed on that class of work before the war. It is not suggested that any Italian automobile manufacturer has ever been in danger of prison, or that this law was necessary to prevent abuse. But it is very convenient for the manufacturer to be able to point to the law when some wealthy and untechnical friend asks to be given factory employment in order to escape active military obligations. There appear to be sufficient men to supply not only army requirements but to make possible the production of cars for export. Obviously the value of exports has decreased, but it is not by any means a negligible quantity, some factories making quite important shipments overseas.

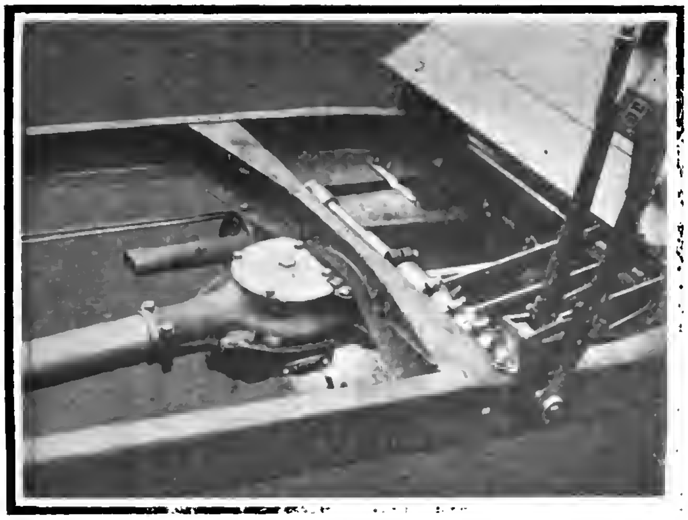
The greatest difference between Italy and her Allies is that she is able to produce within her own territory all the automobiles and trucks required for civil and military purposes. After very close inquiry I have been unable to discover a single foreign automobile in Italian army service. Trace was found of a sample White and a Denby truck at Rome, but it does not appear that any orders have been obtained for these. After England, France and Belgium, where American trucks are now as well known as the native article, it is a decided contrast to come into a country where all automobiles are made on the spot. Even Ford has failed to make any impression in King Emmanuel's territory. Italian automobile buyers belong to the wealthier classes of society and cannot be interested in the cheaper grades of cars. Thus the low-priced American cars failed to get any important hold before the war and have not been adopted since.

The first effect of the war was to make the Italian factories realize their dependence on Germany and Belgium for magnetos, forgings and stampings and certain steels. But the stoppage of supplies only came gradually and for several months after Germany was at war with France, England and Russia, she was sending supplies into Italy. Facilities were even given Belgian firms to send their stampings into Italy between August, 1914, and May, 1915.

Obviously Germany expected a return in the form of finished trucks, and it is possible that some went over the border. Indications appear to be, however, that the raw material came in readily and the finished material went out slowly or not at all. When war is threatening, it is an easy matter for government officials to delay cars on the frontier stations. Although there is a shortage of certain materials, the Italian factories began the war with immense stocks and still appear to be unusually well supplied with material.

Seventy-five per cent U. S. Magnetos

The magneto problem has been the most serious, for Germany had a monopoly of this branch of the automobile industry. Supplies are now being obtained from America, about 75 per cent of the automobiles produced in Italy being equipped with magnetos made in U. S. A. The remaining 25 per cent are German magnetos which are still being drawn from stock.



Gearbox on front end of torque tube, Bianchi light car

One important Italian electrical firm has taken up the manufacture of magnetos, but does not appear to have reached an important output at present. English magnetos were first used when the shortage made itself felt, but they were found unsatisfactory and have been abandoned. American magnetos are better, but the average is not high as that of Germany. In one of the most important test shops batteries now have to be used to help start the motors. No Italian car is equipped with battery ignition in any form. A few French magnetos have come through, but the objection to them is that they cost nearly twice as much as those of American origin.

Italy Makes Own Castings

Italy is entirely independent of outside supplies for iron, steel, and aluminium castings. Her cylinder castings are undoubtedly the finest in the world, and are all made at home. Fiat, Lancia and Scat are three of the leading firms making their own castings. Italian cars carry a greater proportion of aluminium castings than any others, and all these castings are made in and around Turin. The problem has been to get a steady supply of forgings and tool steels, for in these Italy was largely dependent on Germany and Belgium. Supplies are now coming from England, America, Switzerland, and a small amount from France, while important forges have been established in Italy and increasing supplies are coming from them.

Considerable trade can be captured here, for the feeling is strong against renewing business relations with German firms after the war. In going through one of the leading factory store rooms I was shown article after article which formerly came from Germany, but is now supplied by the Allies or by America. One example, of little importance in itself, is nevertheless significant. The set of wrenches and tools supplied with a high-grade car was obtained from a German house and was supposed to be of German construction. Quite accidentally it was found that they were made by a well-known American firm. Immediately the order went direct to America. American firms should not overlook the fact that a German distributor will not be in a position to do business outside his own country when peace conditions have been re-established.

There is no shortage of ball bearings; some of the best are made in Italy and supplies are available from Sweden. All raw material has increased in price from 10 to 50 per cent. Tool steels are rather difficult to procure, but on the whole the Italian automobile industry is exceedingly well placed for material, due partly to the fact that enormous stocks were put in before the war, and partly to the fact that Italy is in a great measure self-supporting.

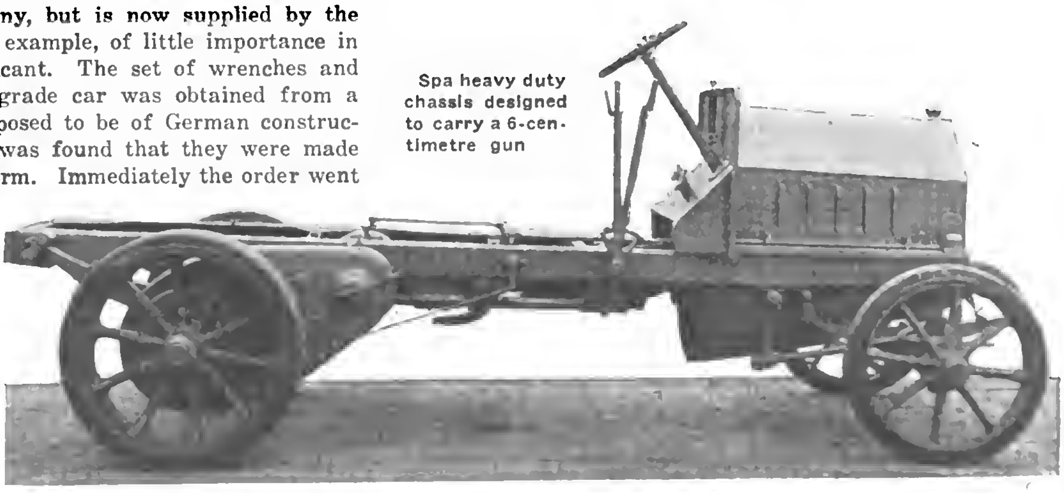
The greatest shortage is in coal and coke. Nearly the whole supply now comes from England, and although there is no danger of this supply failing so long as England retains control of the seas, the Italians would be well pleased if bigger supplies were allowed to come through. Coal has never been a very cheap commodity in Italy, but $35 a ton may be considered a fancy price. Gas coke is sold at $17 a ton. In the picturesque Italian idiom one automobile manufacturer said, "Let England supply the coal and Italy will furnish the blood."

Plenty of Tires Available

It is to be imagined that a German would be afflicted with apoplexy could he see the free use of pneumatic and solid tires in Italy and note the apparently unlimited supply. The leading native manufacturer is Pirelli, who produces pneumatics only, and is able to supply Italy and other allied countries. Michelin has an important factory in Turin, where pneumatics only are made. Since the war Goodrich has established an Italian branch near the Fiat factory, at Turin, and appears to be furnishing an immense number of solid tires to the Italian government. The American establishment is next door to what was recently the headquarters of the Continental Tire Co. The German name has been removed, but the trade mark still remains as a souvenir of a firm which, everybody declares, will *not* be re-established after the war.

A few English tire manufacturers are represented on the Italian market, but there never was much outside demand for pneumatics, and Goodrich doubtless does more business with solid tires than all foreign firms combined. Another American firm which attempted to fill Italian war orders had an unfortunate experience. An order for 5000 solid tires was obtained through a French house, and a first batch of 500 was delivered. These were the first band tires the firm had made and they proved so unsatisfactory that the president of the company had to make a special trip to Italy. It was agreed to replace the first batch free of cost, but the second shipment did not prove very much better.

The authorities appear to have realized that they were being experimented on and have considered cancelling the contract. This firm has never sold solid tires on the American market. Demountable solid tires are unknown in Italy; all trucks, without exception, have pressed on tires. Straight side pneumatic tires are not used.



Spa heavy duty chassis designed to carry a 6-centimetre gun

One of the effects of the war has been to stimulate the demand for automobile trucks among business firms. Up to a year ago the number of business trucks in Italy was not very great, but as the numbers of horses decreased and as the war furnished examples of the utility of trucks, a demand developed among business houses and the home factories have been able to meet it. Prior to the war Italy's specialty was touring car chassis, a comparatively small amount of truck business being done, and most of this was for abroad. The war has made it necessary for everybody to study trucks, with results that are not always quite satisfactory. There is too much adherence to touring car design and too much adaptation of touring car models to truck work.

Turin Is Italy's Detroit

Turin is the headquarters of the Italian automobile industry. Out of a total population of 430,000, about 25,000 or 30,000 persons are directly engaged in the automobile industry. The most important factory is Fiat, which with 10,000 workers on the pay-roll claims to be one of the largest, if not the largest automobile factory in Europe. Other Turin factories without attempting to put them in order of importance, are Lancia, Aquila-Italiana, Scat, Diatto, Itala, Rapid, Spa, Nazzaro, Chiribirri, and the Italian branch of the Gnome Co.

There is a local pride in the Fiat factory so great that every manufacturer, no matter how good his own establishment, will recommend the visitor not to fail to visit the Fiat works.

It is doubtful if any town in Europe possesses five more modern, better equipped, or better managed factories than those of the Fiat, Lancia, Nazzaro, Spa, and the Scat companies. In every case the buildings are well planned, laid out on a big scale, fitted with the most modern equipment, spotlessly clean, and really well managed. With the exception of Fiat the general layout is a big one-story main building divided in the center by the stores. At one side of the stores is the machine section and at the other the assembly department. Thus raw material goes in at one end, is machined, passed into the stores, and passed out at the opposite end to the assemblers. Around the main building are drawing and business offices, test shops, sand blasting, case hardening, nickeling, etc. Land is comparatively cheap, and some of the factories have their own test tracks banked for speed.

Fiat Plant American Type

The Fiat establishment is too big to be laid out on these lines, and the American system of five- or six-story buildings, with electric elevators, is adopted. During the present year the factory has produced 1000 cars per month, the majority of these being trucks varying from 1 to 4 tons. The capital of the company has recently been increased from $3,400,000 to $5,000,000, and stock which was quoted around 90 before the war is now negotiated at 170. Recent extensions will give the Fiat factory an output of 12,000 cars per annum under normal working conditions. It is doubtful if any other factory in Europe produces so many units of a car as the Fiat establishment. All iron and aluminum castings are made by the firm; they also make their own carbureters, radiators, springs, tanks, sheet metal parts, and all standard bodies.

Of late years the factory has designed and built a very large number of its own machine tools.

Although labor is cheap, the average price paid to workmen at the present time being 20 cents an hour (this is rather higher than under peace conditions) modern labor saving appliances are extensively used. There is too much diversity of output to justify all the labor saving machinery found in American factories producing one model only, but the average compares favorably with the best equipped American shops.

One of the finest of the many departments is the motor test room. The motor beds are in two rows on each side of the building and have the exhaust, and inlet and outlet water pipes cast in them; the gasoline lead is also permanently attached to the bed. Electric dynamometers run on rails in front of each row of motor stands. When the motor is put on its stand it is not moved until all tests are completed. It is first run light, then the dynamometer is brought in front of it, connected up, and the motor tested under load. The shop is remarkably neat and tidy and permits of the best work in the shortest possible time. Adjoining are test shops for gearboxes and axles, an examination department in which all motors are taken down and examined after undergoing the bench test, and a sound-proof room for motors.

Gearbox forming unit construction internal foot brake and aluminum dash of Newton light car

Full floating axle of Newton light car. Note neat brake control

The racing and experimental departments and test shops are in the same neighborhood, but these are entirely independent of the ordinary work and are in charge of special staffs. Throughout the war these departments have been working as in normal times, new models being developed, and during my visit I was shown a 300-hp. racing motor on the test bench with which it is intended to better the Fiat straightaway record put up by Arthur Duray at Ostend, Belgium.

In this connection it is worth mentioning that Duray's 300-hp. Fiat is in the finished car department at Turin by the side of the King of Serbia's recently repaired limousine. This racing machine, which is the biggest ever put on the road, with a height of about 5 ft. 8 in., is owned by a Russian prince. After Duray had set up the world's record, the French authorities refused to grant a license for this huge machine to be run on French roads. As Russia does not possess any highways suitable for speeds of 140 miles an hour, the car is in cold storage.

(To be continued)

The Romance of Accessories

Accessories Have Done Much to Make Motoring What It Is To-day and from Adjuncts Many of Them Have Developed Into Necessities

THE automobile of 1916 would be a very different sort of a machine had it not been for the activities of the accessory manufacturer during the past fifteen years. Taking just the high spots, imagine a car without a speedometer, without starting and lighting, without curtains to the top; even one may add, without good spark plugs and without an automatic carbureter.

All these things and many others, too, were developed as accessories, as things upon which the owner of a motor car might be persuaded to spend his money. The history of the accessory industry repeats itself rapidly. Some bright inventor sees an opportunity to make an automobile a more convenient machine to own or to use, something which makes for efficiency, for comfort or for luxury. To develop it capital is found, after experiment has proved its value, and it then appears in a form or forms which are readily adaptable to existing cars. Ingenuity is turned to devising means for applying it to cars never designed to take it, and in the Ford starter business we see the highest possible phase of this.

Stock Equipment Is Goal

Then the next stage may be quick or slow in coming, it depends upon how popular the accessory becomes. If it reaches a degree of favor which causes it to be seen on a large proportion of cars the automobile manufacturer becomes interested and adoption by one may lead to general use, as has happened with the speedometer, as has happened with the starter, and as is happening with the engine driven tire pump.

When the manufacturer takes up an accessory and begins to order in his tens of thousands that accessory becomes a component just as a motor or an axle so becomes. A true accessory is something which is not part of the original makeup, something which the user can buy and add as it pleases him so to do. Perhaps the day will come when there are no more accessories, when every automobile is complete to a point where nothing more can be added, but it is unlikely that any who read these words will live to see that day. Meanwhile there is scarcely a car that cannot be made more comfortable, more efficient, or more luxurious by the expenditure of a few dollars now and then. Also it must be remembered that there are things which wear out. It is necessary to replace spark plugs at regular intervals, warning signals of the various sorts grow old faster than the car that carries them and new things may come along worthy of attachment, just as a motor operated tire pump is well worth adding to a sound chassis not so provided by its maker.

Non-Stock New Parts

Then, too, there are the repair shop accessory opportunities. When an old car with many years' service ahead of it is being limbered up there offers a chance to put in new piston rings of a better pattern, to substitute aluminum pistons, perhaps to change the carbureter for a more efficient and economical instrument. This is a condition which will be with us always, at least as long as the automobile goes on improving from year to year, as it seems likely to do for a very long time indeed.

Of course there are a few accessories offered for sale that have little worth, that are just novelties with no useful purpose, but they are a very small minority indeed. Practically everything to be found in a well stocked store of automobile accessories is worth the price asked for it and many motorists lose a great deal by not paying sufficient attention to their dealer's display. By a proper and judicious purchase of new fittings and new attachments an old car can be kept in efficient and convenient condition for several years longer than if run in its original state all the time. No man hesitates to refit his home with metallic filament electric lamps in place of the more extravagant carbon ones; to buy a new rug or a new chair from time to time. Why, therefore, should he neglect to maintain the usefulness and even the appearance of his car?

Progress In Detail Noted

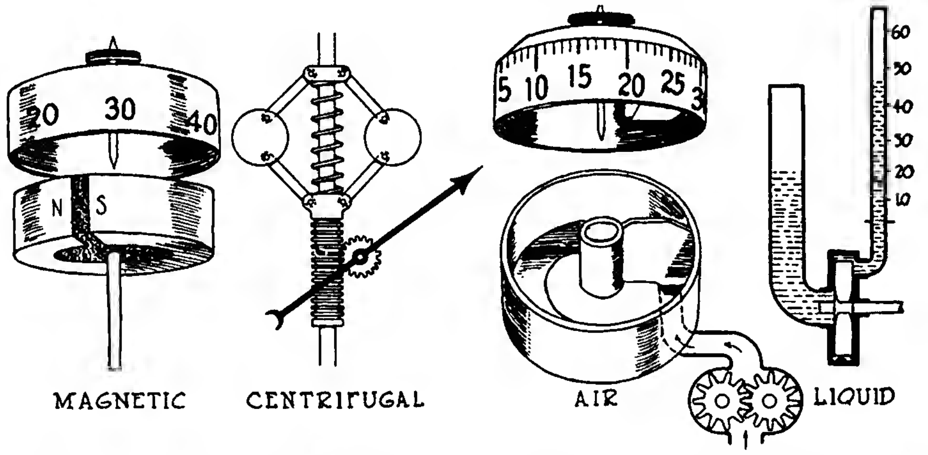
Whether stock parts or true accessories the great change in the past year is in sturdiness of design. Simpler and stronger parts, better adapted to the rough and tumble usage of automobile service, have become the rule. It is particularly noticeable that quality is taking its proper place as a selling argument, and it seems that the buyer is coming to understand that a good article at a fair price is better value than a poor accessory at any price.

Amongst the major accessories, the things which manufacturers have taken up and are now taking up THE AUTOMOBILE reviewed those of the greatest importance during the fall. There remain several others in the making of which progress is to be recorded and these are dealt with in a general way in the pages which follow.

Better Trip Reset on 1916 Speedometers

Flush Mountings for Instrument Boards also a Feature —No Changes in Principle

Magnetic, Centrifugal, Air and Liquid Are Four Systems Used



The four principles of speedometer operation: Magnetic, in which a revolving magnet exerts its drag on the dial; centrifugal, in which revolving weights supply the energy due to centrifugal force; air, in which a current of air flows against a vane carrying the dial, and liquid, in which a column of liquid is lifted a height proportional to the speed of pump drive

WHILE at first glance it would hardly seem that road route books and speedometers could be in any way interconnected as regards the design of the speed and distance recording instrument, yet the refinements of the year show this to be so. When touring by route book it is essential that the readings of the odometer correspond with the book mileage. Consequently the odometer part of the speedometer, to reach its maximum usefulness must be so arranged that the trip mileage reading can be set to whatever distance is required. The 1916 speedometer is equipped with a wheel or other efficient reset mechanism which permits of this, and the universal adoption of the trip resetting mechanism is the distinctive speedometer improvement of the past year.

The wide adoption of the instrument board has given rise to the second improvement, flush mounting. With this style of mounting only the face of the instrument projects through the instrument board, thus giving a neat appearance which coincides exactly with the harmonizing lines of the interior of the cowl. On some of the high-priced cars an additional speedometer is mounted flush with the back of the driver's seat. The driver's instrument is then carried on a frame at the toe board in the custom-made bodies and the instrument board is abandoned.

Two Main Refinements

These two refinements, the accessible trip reset and the flush mounting, are the two features of speedometer improvement. In fundamental principle none of the makes has been altered and the broad classification of magnetic, centrifugal, air and hydraulic operation includes the four basic methods by which the car speed is transformed into mileage readings on the dial.

The magnetic principle as indicated in Stewart-Warner and American Ever-Ready instruments, utilizes a revolving magnet positively driven from the car wheel or other part. The magnet exerts its influence on a metal part which is separated from it by an air gap and which in turn is connected with the indicating mechanism. The metal part is generally aluminum as the inertia of the part must be kept as low as possible to make the speedometer quickly sensible to speed changes. A feature of the magnetic design is that the travel of the dial bears a direct ratio to the speed of travel of the magnet, and in order to compensate for changes in the drag due to temperature differences, a compensating unit is fitted.

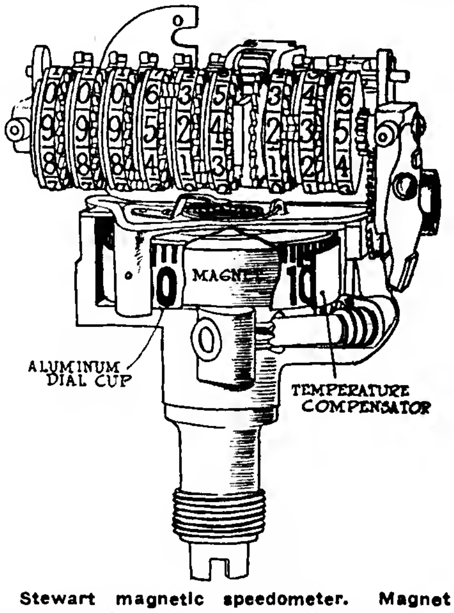
Centrifugal control as utilized in speedometers is very much the same as that on a fly-ball engine governor. Standard, Johns-Manville, Sears-Cross, Corbin-Brown, Hoffeker and Garford use this principle. Weights are mounted on the revolving shaft by bell crank levers which allow them to travel further from the axis of the shaft as the speed of the drive increases. The centrifugal force of the weights increases as the square of the velocity of the shaft.

Weights Actuate Needle

This tendency of the weights to fly from the axial center of the shaft under the influence of centrifugal force furnishes the basis of the indicating needle movement. An ingenious feature in centrifugal design is that although the movement of the weights would naturally vary as the square of the speed, the levers or cams governing the movement are so calculated that calibrations on the dial are uniform or nearly so. Another feature which is carefully watched is the balance of the weights. The governors are made very sensitive so that even at low speeds the correct rate of travel may be indicated. Improvements in this direction have been made within a year by at least one of the centrifugal speedometer manufacturers.

The air principle is used only on one make, the Van Sicklen, in which a blast of air from a pump within the speedometer forms the source of operation of the indicator needle. As the speed of the drive increases the volume of air flow becomes greater, thereby increasing the travel of a pivoted dial, calibration of which is effected by governing the size of the passages through which the air flows.

One instrument, the Veeder, which employs the hydraulic system, uses a centrifugal pump which is connected



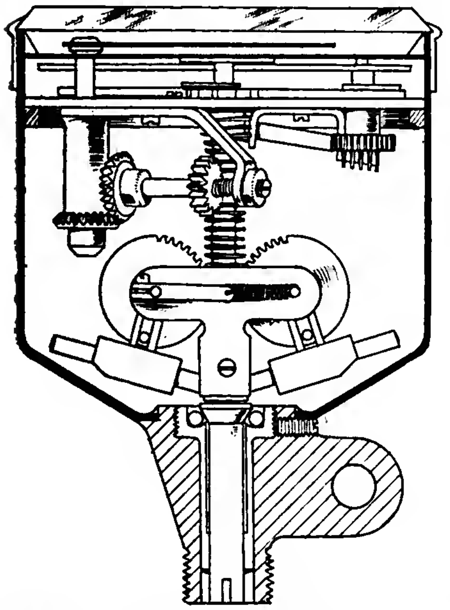
Stewart magnetic speedometer. Magnet revolves exerting pull on aluminum cup carrying the dial. The faster the magnet revolves the greater will be the pull on the cup against the action of the hair spring above the cup. Temperature compensation is taken care of by a thermostat which surrounds the dial with the drive and which lifts a liquid to a height proportional with the speed of the drive. The tube in which the colored liquid is lifted is calibrated to register speed.

Stewart-Warner

Stewart-Warner magnetic instruments are made with flush mounting and with a convenient form of wheel reset. The instrument has but one moving part, a circular magnet over which fits an inverted aluminum cup. This cup does not touch the magnet, being separated from it by an air gap through which the lines of magnetic force travel. On the outer rim of the cup is the dial.

The magnet is positively driven as the car travels, at a rate proportional to the speed of the car and the faster the magnet revolves the greater the pull exerted on the cup and dial. A hair spring controls the movement of the cup and the greater the pull exerted by the revolving magnet the further the cup is pulled against the action of the spring.

The indication of very low speeds is one of the features of the Stewart instrument. The tungsten steel magnet being in the form of a circular ring acts as its own keeper, thus rendering it permanent. Delicacy of action is secured by having the pivot point mounted on a jeweled bearing and the upper support of the cup is also a jewel bearing. The temperature compensator is a thermostat which is nearly a complete circle surrounding the dial but leaving the part which comes before the reading window uninterrupted. This compensator maintains the correct adjustment of the hair spring under varying temperature conditions.



Standard centrifugal speedometer. The feature of this instrument is the ingenious arrangement of the spring tension applied to the levers mounted on the governor weights. By this system of levers it is possible to have the divisions on the dial of the instrument equally spaced, although the centrifugal force varies with the square of the speed. The movement of the rack is proportional to the speed of the car

The passenger car types cover a wide range and can be secured in various combinations with clocks and electric lamps. Probably the most important announcement made by the Stewart-Warner Corporation regarding its speedometer line is the Ford type at $10, which is the lowest price of any instrument.

Standard Thermometer

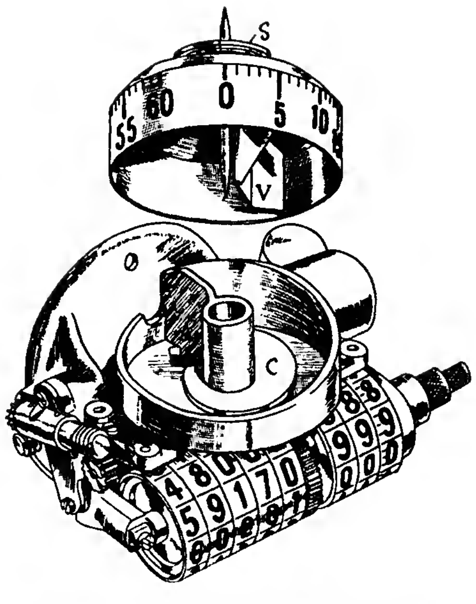
Illustrating the tendency toward accessible and quick trip resetting mechanism the Standard Thermometer Co. has incorporated in its 1916 instrument a wheel reset which can be operated in 3 sec. This new resetting mechanism and a model adapted for rear drive are the principal improvements. Two distinct types of speedometers are at present being made by this concern, both operating on the centrifugal principle and known respectively as the Ford and Chevrolet 4-90 designs. There is no difference between these two in respect to the speed and distance measuring parts, the only variation being in the form of case and method of installation on the dash or control board.

The Chevrolet 4-90 type represents up-to-date practice in having the speedometer mounting flush with the control board. All portions of the case and supporting flange are finished in nickel plate with the trip reset button projecting from the upper right portion of the flange.

In carrying out the centrifugal principle two weights are carried upon a light arbor, driven through a flexible shaft from the front wheel. The rotation of the arbor causes the weights to fly from the axial center due to centrifugal force and as they move a sleeve is actuated, which slides along the shaft, a distance proportional to the speed of the car. The movement of the sleeve is transmitted to the indicating hand on the dial by means of a rack or series of rings turned on the surface of the sliding sleeves. These rings being in engagement with a toothed sector which, by means of a multiplying gear train, actuates the indicating hand.

Since the indicating hand of the speedometer is not actuated by the rotating arbor but by the centrifugal weights the speedometer hand will not vary in its indication unless the speed of the car varies. This is true because only an increase or decrease of speed will cause the weights to depart from or approach the axial center.

A feature of the speedometer is the uniform scale divisions throughout the entire range of speeds. Although the centrifugal force increases as the square of the angular velocity, the compensating arrangement in the Standard speedometer due to the use of suitably formed levers mounted in conjunction with the weights and spring tension units permits of the uniform speed division.

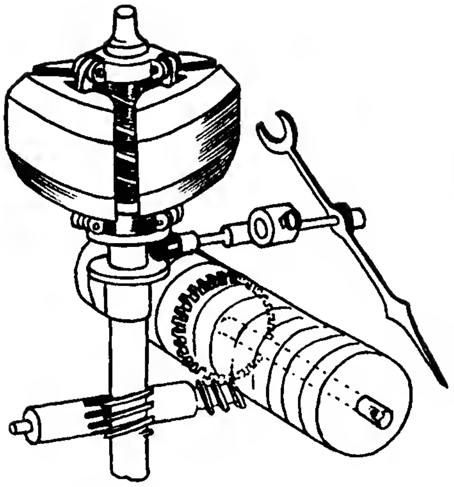


Van Sicklen air-system speedometer. Air current from gear pump enters through an opening on the other side of the wall from the outlet A and flows against the vane V in the inverted cup, which carries the dial. The cam C regulates the escapage of the air and compensates for the greater flow at increased speeds. The dial cup is limited in its movement by the hair spring S

A new development makes impossible an error in the trip reading of more than 0.05 mile. This gives a feature which is valuable in following mileage readings in route books, as it is often impossible to determine if the car is in the first or last half of a tenth mile. Another new feature is a new pressed steel adjustment bracket for Fords installed by removing the right spindle nut. The Ford type sells for $12 and the Chevrolet design for $15.

Van Sicklen

The Van Sicklen air speedometer utilizes the drive of the flexible shaft to create an air current by a small gear pump. This air current flows against a vane on a pivoted aluminum cup on the outside of which is the moving dial. A hair spring holds the cup normally at zero, and as the strength of the air current increases the vane tends to rotate the cup against the hair spring to the correct registering position. The direct means of governing the travel of the dial is by varying the volume of air increases, but the pressure is prevented from rising by the proper governing of the air openings. Thus, for any position of the dial there is a definite amount of air flow which does not vary until the speed varies, thus keeping the dial steady at definite speeds. Conforming



Johns-Manville centrifugal speedometer. The centrifugal weights are carried on bell crank levers and are controlled by a spring. The combination of spring and levers is such as to proportion the travel of the sleeve to the speed of the car. The sleeve action is transmitted to the needle through a small crank. The odometer action is by worm and gear

to modern practice a wheel reset is used so that any mileage desired may be set on the trip odometer.

Corbin-Brown

Improvements on Corbin-Brown centrifugal speedometers, that are now also made in the flush mounted type with wheel reset, include a new form of attaching bracket which allows the instrument to be adjusted to four positions on either the right or left side of the dash by merely removing two set screws. The swivel gear section in which the gears are made and hardened, is in one piece with the shaft, to which the cables are attached. Large collars hold the gears in correct position and considerable space remains for grease to be packed into the housing.

The centrifugal weights are balanced about the shaft and as they fly from the center they move a rack consisting of a number of rings turned on the vertical shaft. As the rack moves up or down, according to the speed variations, the hand is caused to travel along the dial through a gear train mechanism.

Prices vary from a Ford type at $12 up to $30 for a flush-mounted design with a 3-in. dial.

Johns-Manville

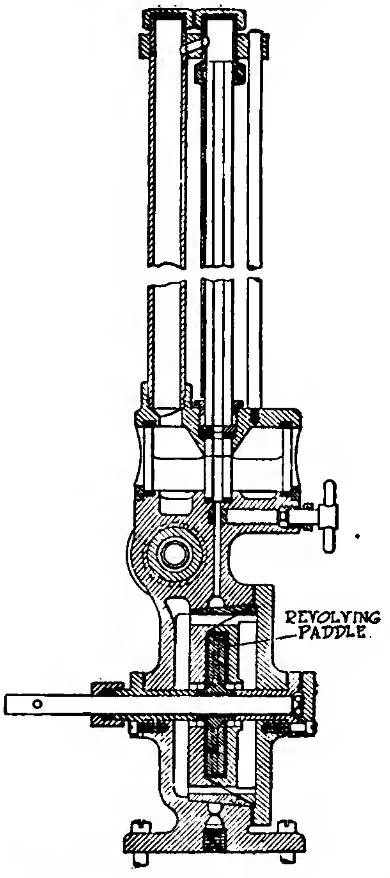
The Johns-Manville centrifugal speedometer is the development of what was formerly known as the Jones. The instrument has been redesigned so that now the entire mechanism is assembled as a unit on a framework, before being put in the shell or casing. This framework can be lifted out of the shell allowing an easy inspection. The instantaneous reset plunger has been replaced by a wheel reset which allows of putting the trip mileage at any figure. Another improvement is in rendering the governor mechanism more sensitive so that it will accurately indicate very low speeds. Better balance of the weights, thus eliminating the vibration of the indicating hand, has been secured. The speed scale is redesigned, giving increased scope with larger figures and the indicator pointer does not pass in front of the odometer window to obscure the figures on mileage.

Johns-Manville, in working out the centrifugal system, uses three balanced brass weights connected with links and swinging freely on fixed pivots mounted on the driving spindle. When the spindle is rotated through the medium of gears and the flexible shaft the weights tend to separate, operating a cam movement which moves the indicating hand to the correct position on the speed scale.

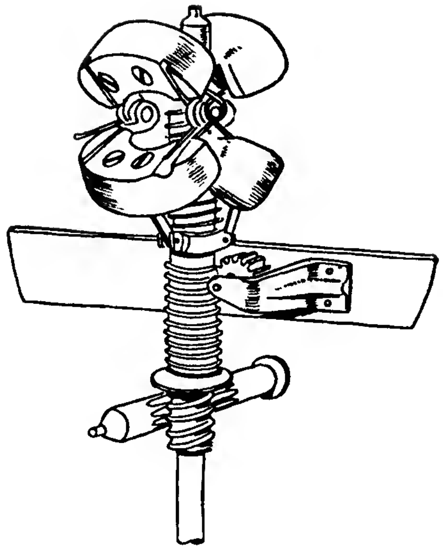
The season mileage reads up to 100,000 and the trip mileage to 100. The number of models manufactured is nine, four of which are 3¼ in. diameter, four of 4-in. diameter and a special model for Fords. The 3¼-in. instruments range from $25 to $30 in price, and the 4-in. $50 to $60. The Ford type is $12.

Hoffecker

The Hoffecker models include a new Ford type at $12. This has a wheel reset and the detail improvements show that the number of working parts have been reduced and rendered stronger than heretofore. The instrument has a 100,000-mile season mileage and registers a speed up to 50 m.p.h. Trip mileage is shown by a separate hand which travels around the same dial as the speeds are recorded upon but with a separate scale outside of the speed scale. The total trip mileage is 100.



Veeder tachodometer. The liquid or hydraulic principle is utilized in this. The centrifugal pump lifts a column of liquid to a height proportional to the speed



Elements of the Corbin-Brown speedometer showing how the centrifugal principle is worked out. The weights actuate a cylindrical sleeve carrying a rack which is made up of a series of rings turned on the sleeve. The odometer system is operated by the worm turned on the shaft below the rack

Veeder

Veeder speed indicating instruments have not been changed for 1916. The hub odometer is the feature of the Veeder line. This instrument is mounted on the hub of the wheel and registers the distance traveled backward as well as forward. It is sealed on the hub of the wheel and cannot be removed except by breaking the seal. The tachodometer is the instrument for registering both mileage and speed and, as previously explained, the speed is indicated by the height of a column of liquid which is governed by a centrifugal pump. With all fittings this sells for $50.

American

The American Ever-Ready magnetic type is made in four models, one of which has been changed for 1916. All are of the needle-indicating dial design. The 60-mile instrument with season mileage only lists at $15 and with trip mileage at $20. In addition there are two 80-mile designs at $25.

Sears-Cross

A new Ford model has been brought out by Sears-Cross under the trade name of Spedindicator.

Horns Better and Lower in Price

Electric Types Continue to Gain in Popularity with the Universal Use of Electric Starting and Lighting Systems—Simpler and More Accessible—Hand Horns Also Improve Greatly

REFLECTING the progress and tendencies in automobile design, the developments in the horn field during the past year have been toward lower prices, simplified construction, improved workmanship and better quality materials, together with greater accessibility of parts for lubrication and adjustment. There has been another tendency, too, peculiar to the horn field, which is toward rendering the instruments more flexible in tone, that is, enabling the operator to evoke either a loud, startling note of warning for emergencies or a softer, more courteous tone for occasions where there is no immediate danger but the car driver feels that pedestrians or other drivers should be apprised of his coming.

In motor-driven constructions, there is a tendency toward the use of horizontally-disposed motors actuating a button on the diaphragm by a toothed cam or wheel on the end of the motor shaft, the angle of impact differing in various makes.

An interesting development in hand-operated signals is the introduction of the underhood type in which the standard lever is used, but instead of having this directly attached to the horn, it is mounted in a casing which can be attached anywhere for easy operation while the impulse is transmitted to the horn under the hood through a flexible shaft.

Quantity production and the adoption of improved manufacturing methods are responsible for many refinements. Greater care has been expended upon design, there being more instances than ever before where the manufacturer has provided adequate bearings, automatic lubrication for the working parts and greater durability, which is to be expected from both the quality of the materials used and the arrangement of the components for least wear and maximum ease of operation.

Prices Are Much Lower

The manufacture of automobile horns in quantity, bringing with it the improvements mentioned, has also brought much lower prices, especially in the hand-operated and vibrator classes, though there are also a number of motor-driven signals at prices very much lower than any listed at the beginning of last year. In fact, it is now possible to buy a good motor-driven horn at a lower price than was charged for a hand-operated type a year ago. As for the prices of the hand horns, simple, strong constructions are now obtainable at about half the price demanded for similar instruments at the beginning of 1915.

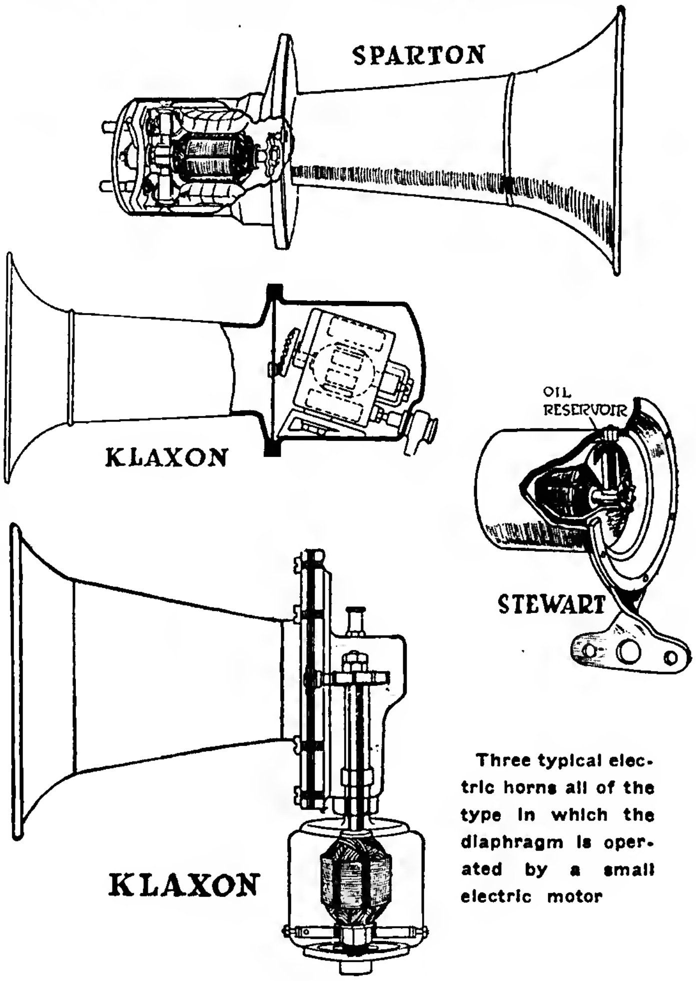
Accessibility Is Greater

In the way of making things easy for the car owner, increased accessibility for adjustment, lubrication or possible repair show marked advances over the progress registered in these features at the opening of 1915. Automatic lubrication of the parts, where friction is a factor, may also be included in this category. It is these little bits of thoughtfulness on the part of the manufacturer which go to make automobiling more of a joy each year and automatically enlarge the field for his instruments by the reflex action of creating more automobilists. This year some horns have adjustments outside where they were formerly inside the casing and more or less fussing was required before the pitch or tone could be altered in the slightest degree. It is much easier to get at the parts for inspection and oiling, it being no longer necessary to practically disassemble the entire horn to carry out these simple steps. In some of the constructions now employed it is but a moment's task to loosen a thumb nut or two and the entire mechanism is revealed. Many diaphragm types are adjusted for pitch by turning the screw button in the diaphragm.

Another feature is the use of an oil pad which keeps all the working parts of the horn constantly lubricated, while wells for retaining and distributing the oil applied to horns with the conventional lubricating arrangement are more widely used and better shaped than was formerly the case.

Electric Horns Are Improved

A notable improvement in motor-driven types is the simplified construction adopted by the Sparton, manufactured by the Sparks-Withington Co., Jackson, Mich., the housing having been made a much better manufacturing proposition by replacing the curved exterior with a straight type, while the adjustment has been brought outside so that the pitch, etc., may be varied simply by turning a thumb nut. The



Three typical electric horns all of the type in which the diaphragm is operated by a small electric motor commutator is much more accessible for inspection and oiling than formerly.

A number of new motor-driven horns have been placed on the market during the past year, a prominent example being the Stewart, made by the Stewart-Warner Speedometer Corp., Chicago, Ill. It is a horizontal type in which a toothed wheel on the end of the motor shaft impinges on the button on the diaphragm. Economy of current is one of the aims in its design as well as light weight and immunity from motor trouble. The large mushroom buttons used with this horn may be operated by a push from any angle with the horn or elbow.

The most recent additions to the line of the Lovell-McConnell Mfg. Co., Newark, N. J., are the U. H. Klaxon and U. H. Klaxet, the former having a straight-side projector and the latter a bell-type projector. Both use the horizontal motor construction in which the motor is set somewhat at an angle so that the toothed cam on the motor shaft strikes the diaphragm button. These two new models are much lower in price than any previous Klaxon instruments of this character. The rest of the line, including the large type L, using a vertical motor, is continued without change in design. A feature of the Klaxon horns for 1916 is that they are all to be finished in a new black enamel called Klaxon black, this step being a reflection of the tendency in car construction to use plain black finishes, doing away with finishes requiring care and polishing on the part of the car owner.

Another concern of importance continuing a standard line of horizontal motor-driven horns is the Automobile Supply Mfg. Co., Brooklyn, N. Y.—manufacturing the Newtone in both outside and underhood styles, as well as a magneto-driven vibrator horn for Fords and the Apollo vibrator type.

In addition to four vibrator types, the Garford Mfg. Co., Elyria, Ohio, has produced the Rexo II, horizontal motor-driven type at a low price, its construction being a good illustration of the possibilities of simplified manufacturing processes, the electrical element being mounted on a one-piece stamping. A feature of this horn is the fact that there are no friction surfaces to lubricate or adjust. The only adjustment necessary is made once a season with a screwdriver to take up wear.

Another horizontal motor-driven horn recently put on the market is the Eaco, produced by the E. A. Laboratories, Inc., Brooklyn, N. Y., which is made in two types, the conventional and underhood styles. In addition to the regular size a smaller size is made for small cars and has no projector.

A horizontal motor design has been added by the Electric Spark Appliance Co., Brooklyn, N. Y., under the name of Olympic, being made in two styles for outside mounting and under the hood. The other types made by this company are vibrator designs in the same styles as the motor-driven.

Two motor-driven horns and two vibrators are made under the name of Samson, by the American Electric Co., Chicago, Ill., both types following standard principles of construction.

A new low-priced vibrator horn for the Ford flywheel current is the Heco, which is made by the Heinze Electric Co., Detroit, Mich.

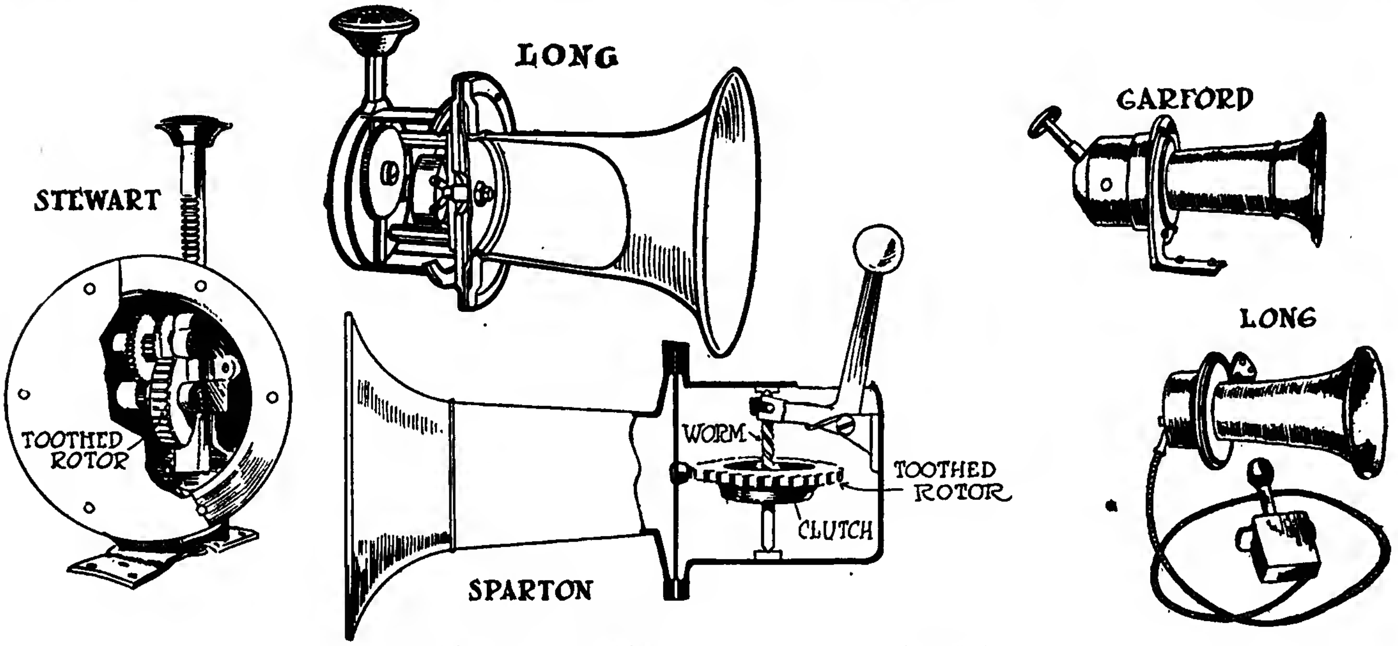
One of the makers who have aimed to produce a motor-driven signal that will not shock or disconcert pedestrians or drivers is the Holtzer-Cabot Electric Co., Brookline, Mass., and Chicago, Ill., which manufactures the Reacto hammer-blow type. This horn is adjusted by simply turning a screw to the left for a louder tone and to the right for a lower tone, it being arranged so that this screw cannot work loose. No tools are required to make the change.

Hand Horns Simpler and Less Expensive

Developments in hand horns have been chiefly in the way of lower prices made possible by increased production and simplified manufacturing processes and in stronger, better and simpler construction. Practically the same improvements which mark the Sparton motor-driven type have been embodied in the hand horns, made by this company, the housing having been treated in exactly the same way to render it a better-appearing and more practical manufacturing proposition, while the exterior adjustment for pitch is also furnished. The horn operates through a nut on a vertical worm shaft which carries the toothed rotor against the diaphragm button.

An important event in the hand horn field, late in 1915, was the taking over of the sales of the Long horn by the Edward A. Cassidy Co., New York City, from the H. W. Johns-Manville Co., the latter concern intending to market a hand horn under its own name early in the spring. An underhood hand type has been added to the Long line, this corresponding to the standard construction except that the operating lever may be located on the side of the driver's seat, on the dash or some other convenient place, whence it operates the horn by means of a cable. The Long construction uses a rack and train of gears to actuate a weighted wheel having rollers radially disposed around its surface to engage the diaphragm button.

The Stewart hand horn, which preceded that company's



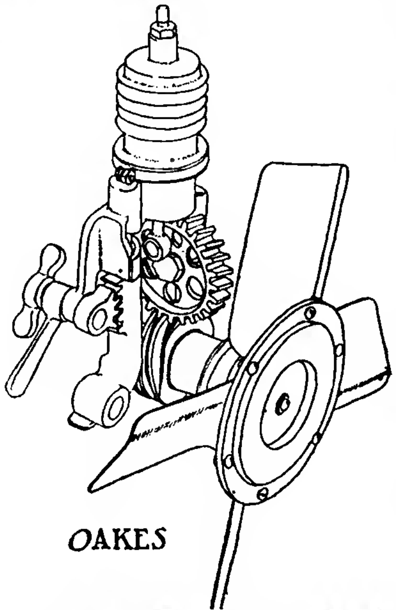
A representative group of mechanically operated horns with hand control motor-driven type embodies standard principles of construction, being of the rack-and-gear type. Besides its lower price for 1916, one of its distinctive features is the use of an oil-soaked felt pad which rubs against bearings and wheels continually, insuring constant lubrication, while another is the use of a double supporting bracket for the horn, which prevents it from getting loose and wobbly even under the most severe usage.

As an indication of the thoughtfulness of the horn manufacturer, the 45-deg. plunger used on the hand Garford is an interesting illustration, this construction permitting maximum ease of operation inasmuch as the operating movement is a compromise between a vertical stroke and a horizontal push. Other features of this horn are: Only four points to oil once a season and three-point suspension mounting bracket insuring rigid attachment. The rotor is on the center line of the horn and the cam wheel is on the shaft between two sets of bearings and acts direct on the diaphragm button.

Many New Hand Horns

Among the new hand horns on the market are: The two new Seiss instruments made by the Seiss Mfg. Co., Toledo, Ohio, which are of the type operated by turning a crank in either direction, the drive being by a bevel pinion and bevel wheel.

The Standard, made by the Standard Metal Mfg. Co., Newark, N. J., employs a vertical spiral shaft and a train of gears. The Eaco made by the E. A. Laboratories Co., Brooklyn, N. Y., in two sizes and employs a rack and pinion mechanism, the rack being on the plunger and the pinion cut in the shaft. Samson-Lion and Samson-Tiger are made by the American Electric Co., Chicago, Ill., the Samson-Lion having a vertical plunger action and the Samson-Tiger being of the rotary type, operated by a twist of the wrist or elbow. The Wondertone, made by the Motor Appurtenances Corp., New York City, has its rotor set at an angle to the diaphragm button instead of perpendicular to it. Thus, the ratchet handle is on the center line of the horn, making it suitable for cars with either right or left steer, the ratchet driving the rotor shaft direct. With this horn it is possible to give either long or short blasts; the A-K, made by the Angsten-Koch Co., Chicago, Ill., in two lengths of projectors. This is a plunger-operated type; the A. W. T., made by the American Watch Tool Co., Waltham, Mass., in which solidity of mounting is obtained by curving the horn body downward so that the supporting feet are short and strong. This allows the operating knob to be placed at a convienient angle for either the hand or foot. The striker may be easily adjusted by unscrewing the horn bell. Another feature is the fact that the bell and the operating knob may be combined to form an emergency drinking cup or receptacle for putting water in the radiator. The Handphone, which is a product of the Automobile Supply Mfg. Co., Brooklyn, N. Y., operates on the plunger principle; the Heco, which is manufactured by the Heinze Electric Co., Detroit, Mich., employs a spirally-cut plunger. This company also makes a horn under the same name especially for trucks which produces a long, rolling note. The Evergood, made by the Emil Grossman Mfg. Co., Brooklyn, N. Y., is another horn built specially for truck use, operating by a vertical plunger.



The Oakes Beartone is a mechanical horn operated directly from the fan and controlled by a button

An Underhood Hand Horn

Some of the leading manufacturers of hand horns who continue their standard models are: Lovell-McConnell Mfg. Co., whose hand Klaxon is a vertical plunger instrument while the hand Klaxonet has a horizontal plunger operated from the rear; the Fitzgerald Mfg. Co., Torrington, Conn., producing the two Clero models, the long projector types being for use on any car while the short projector style is especially for small cars; the Nonpareil Horn Mfg. Co., New York City, which makes the Pilot in two styles with either horizontal or vertical rotary handle working in either direction and also in an underhood type, operated through a 36-in. cable. This company also makes the Noxal ratchet principle hand horn. The Talking Horn Co., Middletown, N. Y., makes the Double-Warning, which is operated by pulling a strap, the signal being repeated when the strap is released. This horn may be mounted either close to the driver or at some distance where it may be operated by a leather cord.

Combined Horn and Fan Styles

There are two leading examples of the combined fan and horn type of construction, these being the Oakes Co., Indianapolis, Ind., which manufactures the mechanically-controlled Beartone for Ford cars, and the Marvel Accessories Mfg. Co., Cleveland, Ohio, which makes the Marvel, using a diaphragm in the hub with a lever-operated vibrating mechanism.

Bulb horns combined with electric types are made, among others, by the Lovell-McConnell Mfg. Co., Newark, N. J., in Klaxon and Klaxonet styles, and the American Electric Co., Chicago, Ill., which makes the Samson.

Exhaust-Operated Types

There are a number of exhaust-operated horns on the market, some of the leading instruments of this type being: Gabriel, made by the Gabriel Horn Mfg. Co., Cleveland, Ohio; Aermore, Fulton Co., Milwaukee, Wis.; Gemco, Gemco Mfg. Co., Milwaukee, Wis.; Autochime, Gray-Hawley Mfg. Co., Detroit, Mich.; Nightingale, Riley-Klotz Mfg. Co., Newark, N. J.; and Barco Chime, Barco Brass & Joint Co., Chicago, Ill., and Princton combination horn and cutout, S. B. R. Specialty Co., East Orange, N. J.

Two Bell Signals

Two of the leading bell type warning signals on the market are the Liberty Bell, made by the Liberty Bell Co., Cleveland, Ohio, and the Trinity Bell, Trinity Bell Electrical Mfg. Co., Chicago, Ill. These signals are rigidly mounted bells having electrically-actuated clappers, and embody other features such as a small red light, which is switched on while the signal is operated, semaphore direction signals, emblems, etc.

Cow Driver Secures Judgment of $150 Against Motorists

Judgment was recently rendered against a motorist for $150 in Alabama. A woman who had been run down and injured while driving a cow and a calf along the highway sued a motorist for her injuries. The court held that as she was giving her entire attention to the animals she was driving, and did not notice the automobile approaching from the rear, she should be given judgment, as travelers on a public highway owe a duty to others traveling on the highway, which duty requires them to so reasonably conduct themselves in the use of the highway that they will not injure other people on the highway.—*Dozier vs. Woods,* 67 *South (Alabama)* 283.

Many Types of Spark Plug

Spark Plugs Have Reached a Stage of Marvelous Reliability, Insulators Are Improved and Life Increased

IT is difficult for a layman to tell the difference between one spark plug and another. For each a special claim is made, some are designed to work particularly well in certain sorts of motor, as instance the long patterns which are made for Ford cars. Others have their chief feature in some device intended to prevent short-circuiting by reason of oil accumulation, but there are two main things the maker of a spark plug strives for. Of these the first is the evolution of means to hold the insulator absolutely tight in the shell so that neither when new nor when old will there be any leak through the packing, and the second is to find an insulator which will withstand the high temperature of the modern type of high-speed engine without injury. There may be added the necessity for sparking points which will not burn away quickly and the desirability for so shaping the insulator that its exposed end shall be as difficult as possible to clog with oil or carbon.

Insulating Materials Improved

Insulating materials such as are now used have taken years to discover, and every year almost, they are improved. Porcelain insulators are no ordinary china factory production, they need to be made of special clays and by special processes. Thousands upon thousands of plug porcelains used to be imported from Europe, prior to July, 1914, and the American market has had to turn around and find home sources of supply. It has done so successfully and to-day the American plugs, better than ever before, are all-American.

High Motor Speeds Make Trouble

Also, increasing motor speeds spell increased average temperature in the cylinder; the plug points and insulator have less time to cool off between each explosion, and this has made the conditions of plug operation more arduous. Better insulators, tighter packing and larger electrodes have been made necessary. All these troubles have been tackled by the manufacturers, have been overcome and done away with, but it has needed much difficult work to bring this about.

It is possible to take the drawings of a motor and to deduce with reasonable accuracy what the performance ought to be. It is not possible to do the same by a spark plug, the differences between one and another are too small on the surface. Inspection does not show how well the packing is done, how impervious to moisture is the porcelain, how high may be the resisting power of the points to burning.

All Plugs Good Value

Plugs may be bought in two ways, on price and on recommendation. It does not always follow that a particular motor will perform any better with expensive plugs than with cheap ones, but a fairly general rule is that really cheap plugs will not give good service in a high-speed engine. In an old motor the expensive plugs may give longer life, but often the cheap ones perform equally as well, and susceptibility to oil has often more to do with design than with material and workmanship in the plug. The high-priced plug is like the high-priced car, it is just as well worth its price as the cheaper type, but the latter is capable of giving excellent satisfaction and of returning an equally full value for the money expended.

Mention has been made of porcelain as an insulator, but this is far from being the only material used, or even the predominant material. In addition there are many mica insulated plugs and many with insulators of natural or artificial stone. The latter might reasonably be classed as a variety of porcelain so, if a division is desired, it might be made by calling porcelain and stone insulated plugs the solid insulator type and so contrasting them with the mica pattern, for mica is obtained in thin sheets and has to be made into insulators by the compression of many small pieces threaded upon a core. The customary method is to punch minute washers from the sheet, to thread them upon the central electrode and clamp the lot together with a nut, a process of heavy compression preceding the final assembly.

Mica and Porcelain Equivalent

It is only possible to generalize in a very broad way, but the most obvious point in favor of mica is that a plug which uses it is less liable to accidental injury, since it cannot very well be chipped or broken by a blow. The stone or porcelain insulator is a little easier to make waterproof and is a simpler manufacturing proposition, once the plant for making the porcelain itself is got in proper shape. There is much argument as to the effect of heat on the two insulating materials and it is worthy of note that racing car drivers are not yet agreed, nor has it ever been settled that either one or the other was always the better for aeroplane motors; and the aeroplane engine provides about as hard a test for plug qualities as can be found.

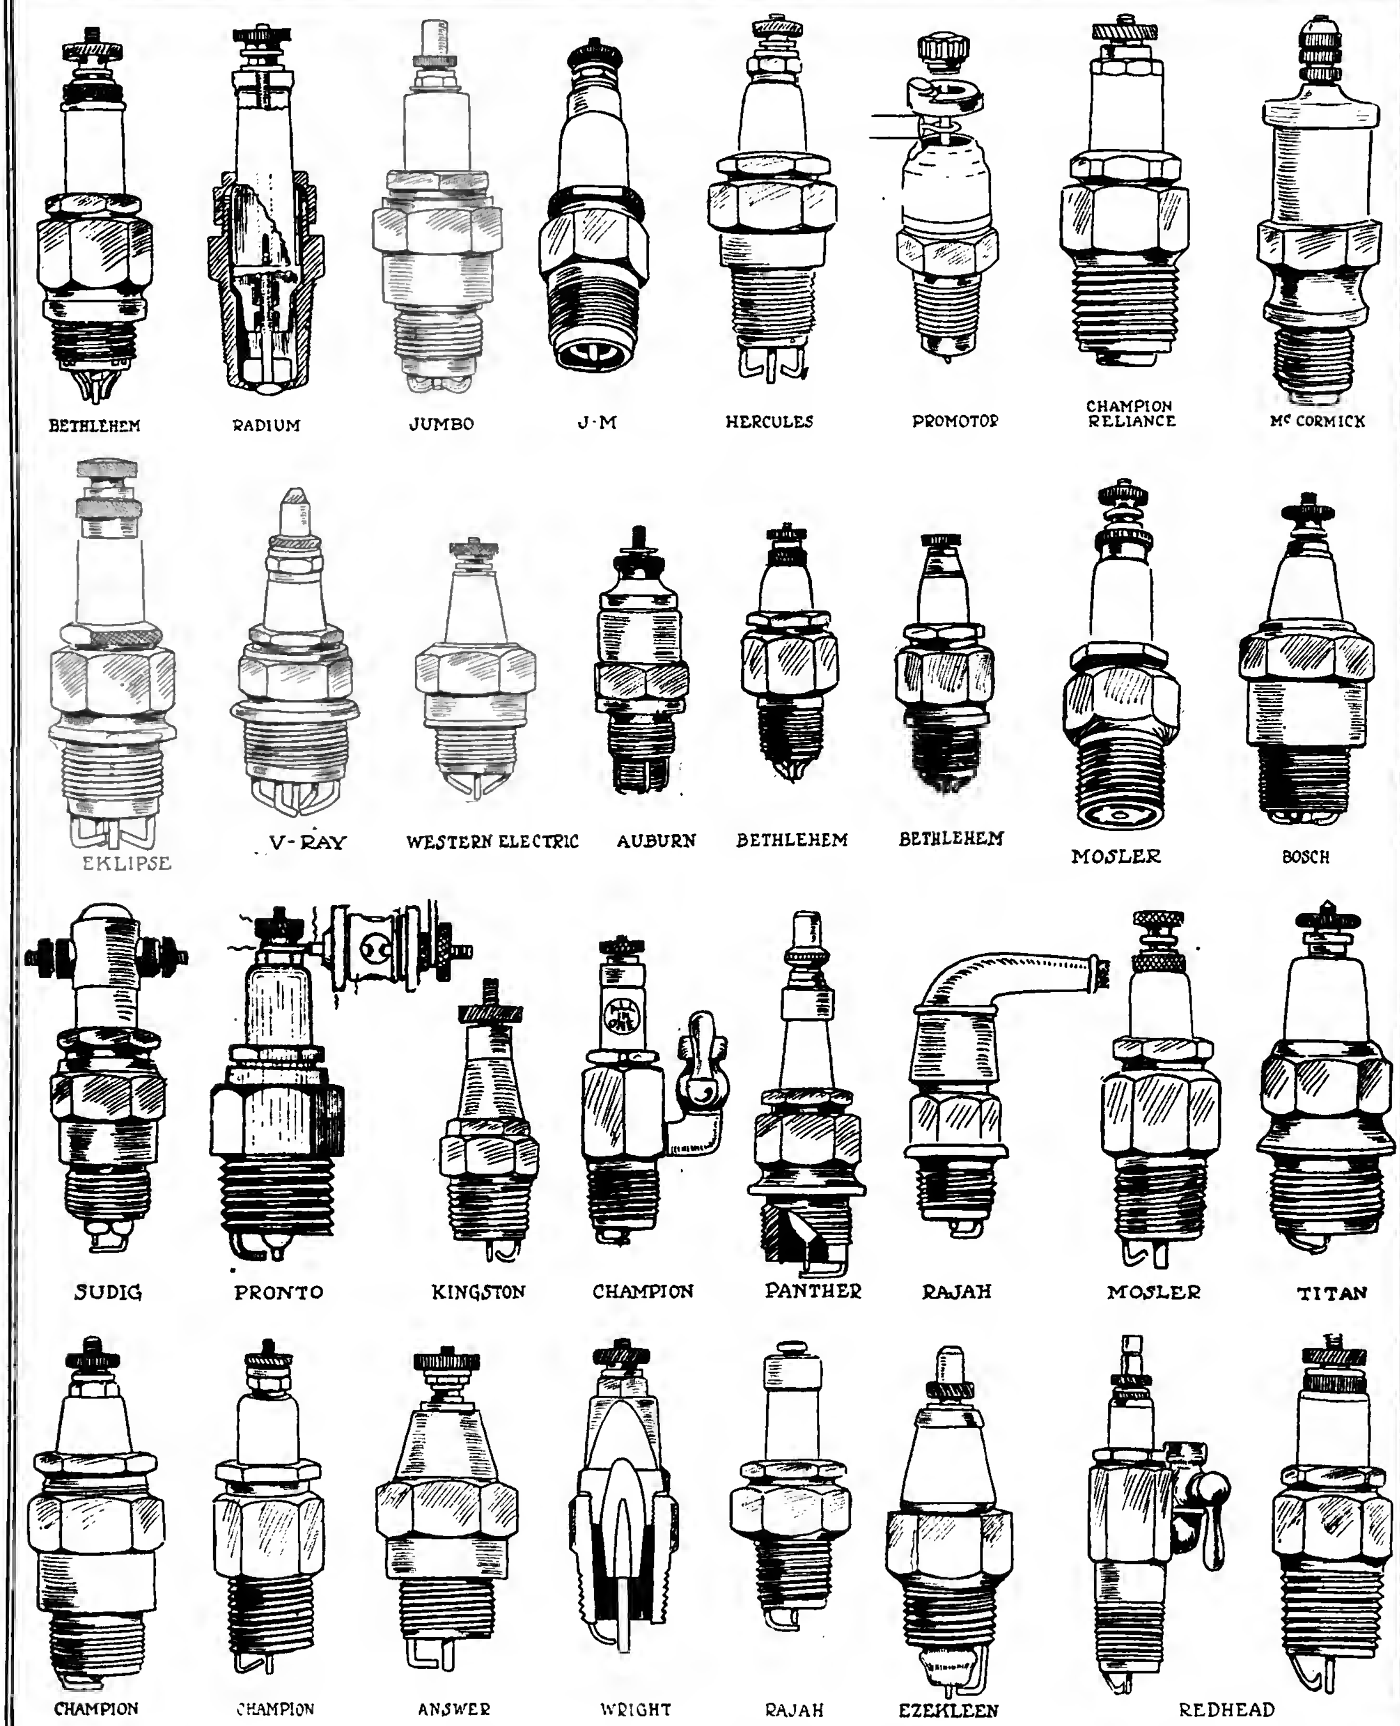
Many Styles of Gap

Another thing which has been productive of much discussion is the relative value of single point electrodes giving but one path for the spark, and multi-point constructions providing two paths or more. There are more single point plugs in use but this does not necessarily prove anything. The single point pattern is easy to clean and is easy to adjust always, and the same applies to many multi-point designs, though not to all. The argument for the multi-point is that when the spark has burned away the two points that are closest together it can go to the next pair and so, by distributing the wear, the time for setting the points will be postponed, but this can be done with single points by increasing their size.

Avoiding Shorts

To prevent shorting it is now an almost universal practice to keep the lower end of the insulator well within the shell of the plug and to give it a wide contact with the shell so that it has opportunity to part with its heat, for the cooler it is kept the slower will carbon deposit upon it. This year it is noticeable that insulators are larger and have a greater area than formerly, this being testimony to the harder conditions under which they are now asked to work.

One of the surprises of the year has been the way in which racing cars managed to overcome plug trouble which, early in the season, was their most serious difficulty. This was done partly by alterations in the motors, but the credit belongs entirely to the spark plug manufacturers, for so speedily tracing the trouble to its source and finding the remedies.



Spark plugs can be divided into two simple classes by grouping those with single point spark gaps and those in which the spark has a choice of route. The sixteen plugs illustrated on the upper half of this page show many different ways of providing more than one spark gap. The sixteen in the lower half of the page are all of the single gap type. Observe the great variation in the shape of the insulator.

Improving the Suspension

There Are Very Many Devices Intended to Assist the Action of the Springs and so Give Greater Comfort in Riding. Wide Variations in Price and Complexity Are to Be Observed

THE term "shock absorber" is commonly used to describe two fundamentally different types of mechanism. The function of a car spring is to give under sudden shocks, and the reason coil springs are not used is that they would give too readily and rebound too vigorously. The leaf spring acts more slowly, because of the friction between the leaves which damps the action, and the true shock absorber is a frictional attachment which, when placed between the frame and axle of a car, will add to the amount of friction inherent in the leaf spring.

Now, a leaf spring with or without a shock absorber has a natural sluggishness which is deliberately sought and is necessary, but this sometimes is not entirely an advantage. Short, sharp shocks are possible which come too quickly and are over too soon for the leaf spring to begin to operate, for such shocks as these we need a greater flexibility.

Supplementary Spring's Purpose

To meet this condition there was created the supplementary spring idea which adds a flexible spring of small amplitude to the end of the leaf spring. Usually a coil spring is employed which, having no lag in action responds instantly to a shock of any size, cares wholly for a small shock and eases the beginning and end of a large shock which is heavy enough to disturb the leaf spring.

There is no reason whatever why a car should not have both shock absorbers and supplementary springs fitted to it, for the functions of each are different, and there have been a few devices designed which combined both principles.

Two Types of Shock Absorbers

Shock absorbers divide into two types also, for some are intended to offer frictional resistance to both the compression and the rebound of the leaf spring, while others are so designed that they move without friction on the compression and only exert restraining force on the rebound.

It cannot be too clearly understood that the use of aids to spring action, whether shock absorbers or supplementary springs, is no reflection upon the original leaf spring. The leaf spring is essentially a compromise affair. Considering its simplicity it is wonderful that it acts as well as it does. Almost any spring is the better for a shock absorber, as it helps it to resist the abnormally large shocks, and it would be wrong to design a leaf spring solely for big blows to the neglect of the little ones.

Similarly, the supplementary spring has its place at the other end of the scale; it cares for shocks too small to affect the leaf spring, so small that a leaf spring could scarcely be designed to absorb them. One might almost regard the effect of the supplementary spring as similar to that of doubling the tire section or of lowering the pressure in the tire.

In the design of shock absorbers the ideal is to provide an easily adjustable amount of friction and frictional surfaces which will be lasting. Also easy attachment is a thing that has had to be studied, and provision made to prevent rattle developing after long use. Each maker has worked out the problem in a different way and all sorts of different ways have been adopted for creating the friction desired. In some instances we see the simple case of two plates or disks gripped together, a sort of diminutive disk clutch. In others the friction of an expanding piston inside a cylinder is used. Others again have a liquid inside which is forced to pass through a small hole.

Different Systems Similar Effects

Each design has its special claims, but there is no reason why they should not all prove equally effective if the mechanical excellence is equal and the proportions are equally well chosen. Design and workmanship count about equally, and there are plenty of shock absorbers having both these qualities highly developed.

Supplementary springs also vary a great deal. We are limited in the range of action that can be allowed by the distance between the frame of the car and the axle, so the travel of a supplementary spring cannot be very great in any case, but having this limitation we can use springs of many types. Some devices are single coil springs, others are duplex, others again use a strong coil spring with a short range and add multiplying levers to increase its amplitude. Some others do not use coil springs of the conventional type, but employ volute springs, or single leaf springs in a flat coil like a clock spring.

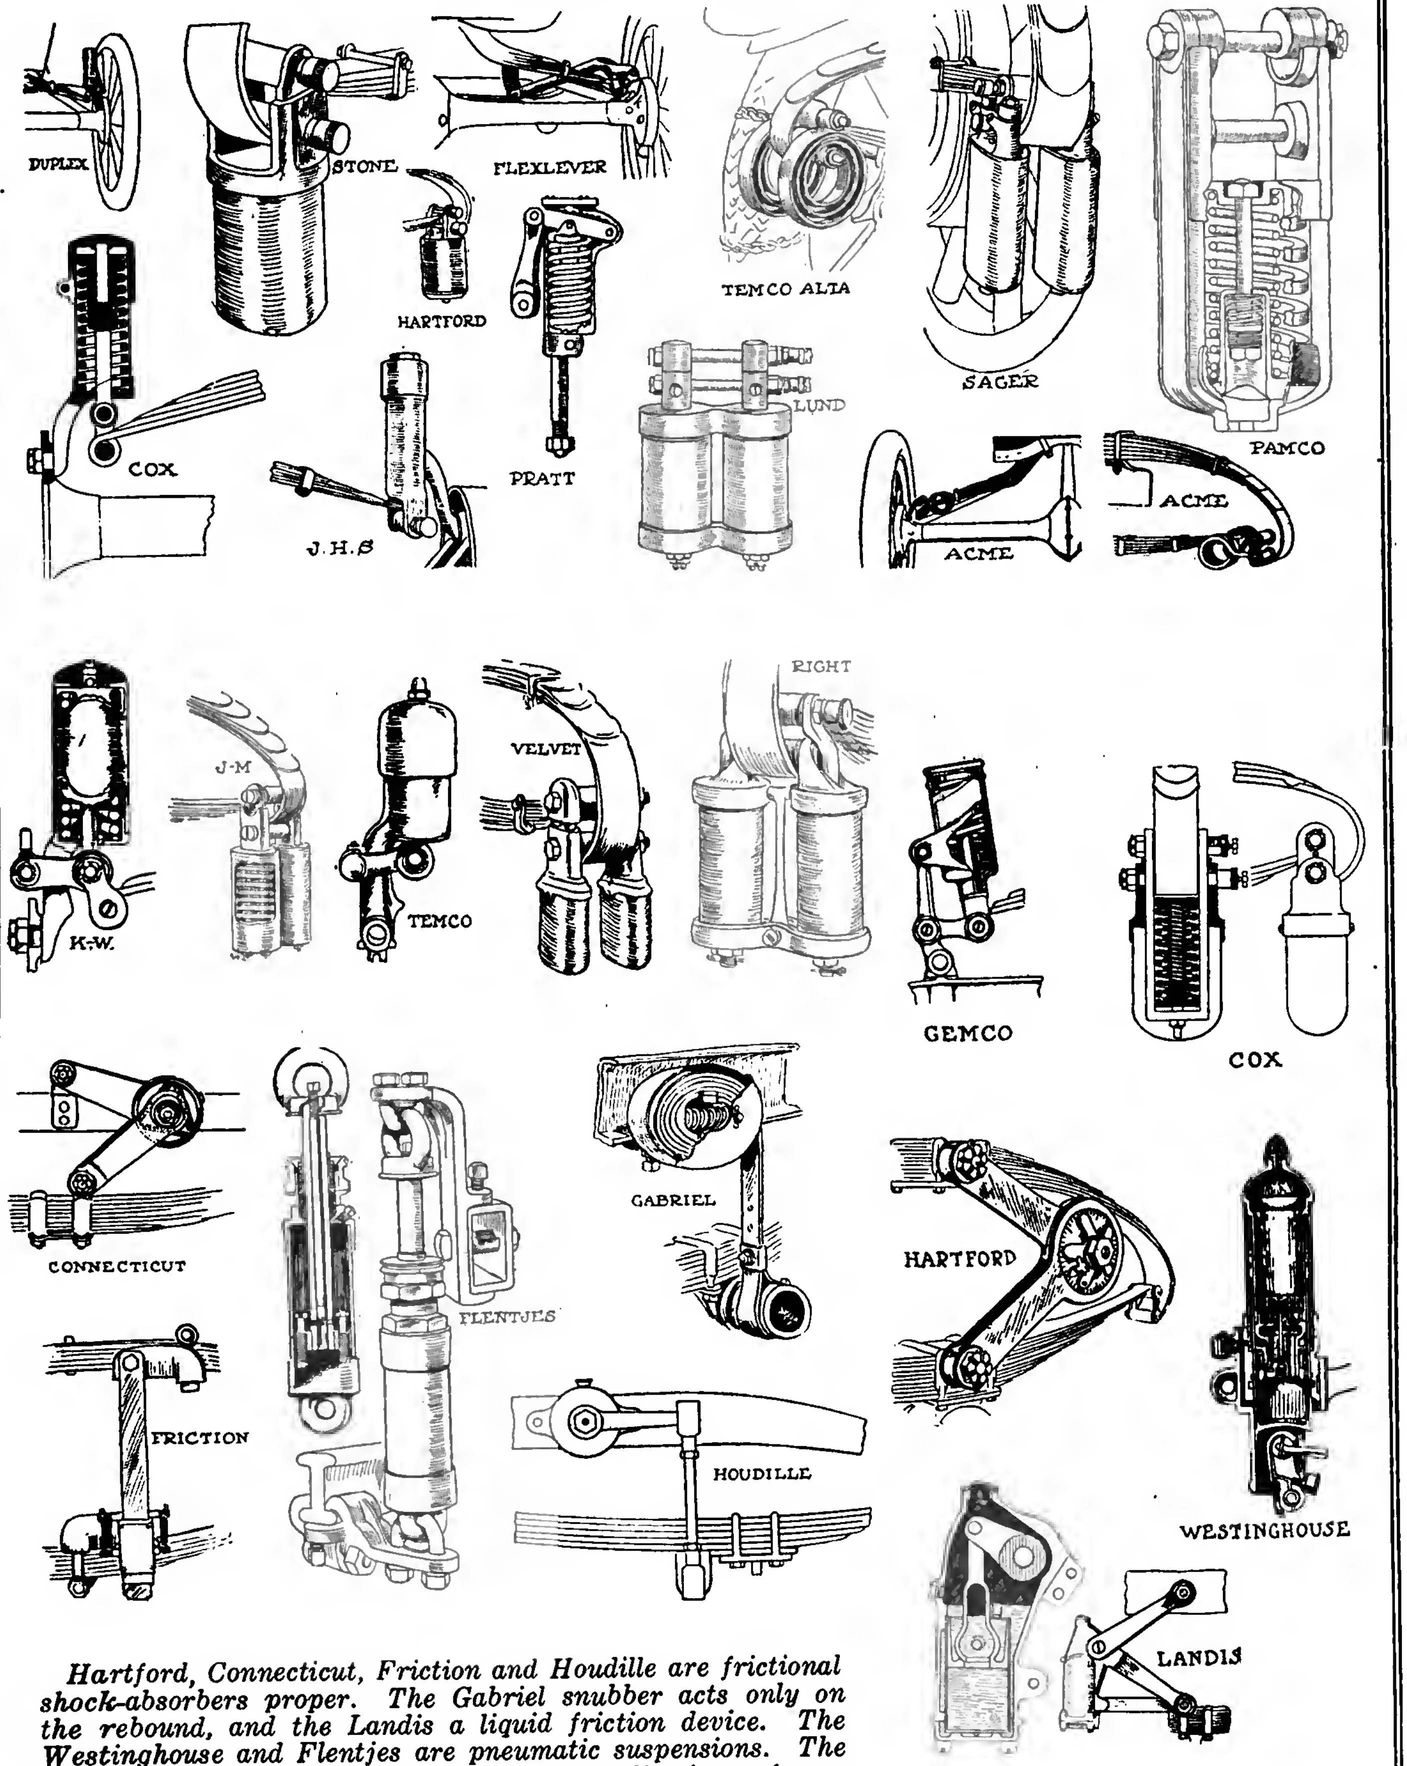
Springs Need Protection

Here again, just as with the frictional spring dampers, the variations in design represent different ways of working out an engineering problem. First, the spring must be properly proportioned to the work it has to do, to the weight of the car and the amplitude of travel. Then any slides or pivots used must be protected against dirt and grit which would cause wear and perhaps squeaking. Lubrication is a little problem by itself, and many ingenious schemes have been evolved to care for it with a maximum of effectiveness and minimum of trouble.

Air Springs Separate Class

There remains the air spring which is an attempt to combine the functions of damper and supplementary spring as well. It is possible to design an air spring which will have all the elasticity of compressed air for absorbing small shocks, and will care for shocks also by the bringing into action of an automatic damping device which puts in frictional resistance in proportion as the violence of the shock increases. Such suspensions have been designed entirely to replace leaf springs, but they have the drawback of being rather clumsy and difficult to work in with an automobile chassis of conventional design.

The air spring can be adapted as a supplementary spring simply, and there are sundry devices of this nature, and it can be also made in such a way that when attached to a leaf spring it is supplementary and shock absorbing also. Probably cost has stood mostly in the way of a much wider use of this variety of attachment, and the air spring may yet have a future before it. To use it most effectively means designing the chassis to suit it.



Hartford, Connecticut, Friction and Houdille are frictional shock-absorbers proper. The Gabriel snubber acts only on the rebound, and the Landis a liquid friction device. The Westinghouse and Flentjes are pneumatic suspensions. The remainder illustrate different sorts and applications of supplementary springs.

Fundamentals of Electric Equipment

Functions of Various Parts and Sundry Quesitons of Design Discussed

By Joseph Bijur

(Concluded from page 90)

As to generator size, if a certain output is wanted at a speed of say 1000 r.p.m. and under other circumstances the same output were to be required at a speed of 500 r.p.m., the slower-running generator would have to be substantially twice as large as the faster-running machine. Conversely, the higher the speed at which the generator may run when it must furnish a certain current, the smaller and cheaper the machine can be. Roughly speaking, the bulk and cost of a generator come down in proportion to the rise in speed at which it is considered necessary for the generator to furnish any given output. This speed is usually found to be that which can be counted on in the hands of a typical driver who is occupied in business pursuits during the day and has time to drive the car only in the evening. Under these conditions no daylight charging can be counted on. For all stops during which the generator is idle and the lamps are turned on, full compensation must be provided. For all of the minutes during which the car is run at a speed when the generator output is less than the current consumption, this deficiency must be made up. Therefore, in order to keep the battery from becoming depleted, the average current supply of the generator must at least equal the average consumption; as a matter of fact it must exceed the consumption, because it can be taken roughly that in order to keep a battery full, the input to the battery must be 25 per cent higher than the output from it. In considering this question we not only have to deal with the current consumption during the periods when lights are left burning, but to take into account the current consumption from starting, as well as the "phantom" load of leaving the car standing idle. During such periods there is a loss of charge in the battery which has to be compensated for exactly the same as if current were taken out of it. From these considerations the following reasoning may be taken. A car driven at night can be counted on to average not over 14 m.p.h. Often this average is taken at 12 m.p.h. If the figure that we consider is 14, then we assume that the current generated during the time when the speed exceeds 14 m.p.h. will compensate for the battery drain of standing, starting and battery loss during periods of no car operation. If the lamp load is assumed to be 8 amp., and the generator current is assumed to be 10 amp. at 14 m.p.h., then for this average speed the generator is supplying 2 amp. more than the current consumed, which excess can be used to compensate for the battery losses above referred to.

If the regulation is such that the current does not ever rise above 10 amp., this amount would be insufficient for a lamp load of 8 amp. and a higher current value would be necessary—something like 14 or 16 amp. constant would be nearer right. This current, however, might greatly overcharge the battery on a car usually operated in daylight hours. Assuming that the regulator is such that for speeds above 14 m.p.h. a higher current will be generated, the value of 10 amp. at 14 m.p.h. would probably suffice. In either event, we see that one of the most critical factors in the adequacy of the generator for its work is its capability to deliver a current in excess of the lamp current at the slow average of night driving. In the example just considered it was essential that the generator should deliver 10 amp. at 14 m.p.h., and assuming that the generator and engine are so arranged that on high gear the generator makes 70 revolutions for each mile per hour of car speed, then it was essential that the generator should deliver 10 amp. at a generator speed of 14 times 70, or 980 revolutions. This is substantially the determining factor in the generator size. If it were adequate to have the generator deliver only 6 amp. at 980 revolutions, or if it were satisfactory to have it deliver 10 amp. at 1200 revolutions, such machines could be made smaller than the one first cited.

Cut-In Speed Not Important

From a consideration of the foregoing it will be evident that the speed at which the generator is connected to the battery and begins to deliver some current, is of relatively small importance. This speed is popularly known as the cut-in speed and refers to the point at which generator charge begins. To understand this better, considering the case first cited, and assuming the generator cut-in point to be at 9 m.p.h., the generator current output will be about as follows:

9 miles per hour	0
10 miles per hour	2 amperes
11 miles per hour	4 amperes
12 miles per hour	6 amperes
13 miles per hour	8 amperes
14 miles per hour	10 amperes

When driving at 13 m.p.h., the generator output only equals the lamp load and no surplus remains to take care of the other battery losses. At speeds below this, the generator output is deficient by greater and greater amounts. It can now be seen that whether this cut-in takes place at 10 m.p.h. or at 4 m.p.h., no assurance can be derived from it that the generator supply will be equal to the demand. It is only the speed at which the generator supply exceeds the load by the desired amount, that is the determining factor in considering whether or not the generator will keep the battery full.

In connection with low cut-in speed, at the point of cut-in, armature reaction has not yet come into play, since the armature only begins to deliver current from here on, and the current is zero or nearly zero. The cut-in point is often determined as the speed at which the generator gives a voltage equal to that of a fully charged battery, or about 7 volts. At this point the resistance of the armature does not come into play, because no current is being carried, and therefore no resistance drop takes place. We can then in a generator get a low cut-in point by disregarding armature reaction and armature resistance and simply wind the generator armature with many turns of fine wire. Such an armature generates the requisite of 7 volts at a low speed and furnishes the low cut-in which has often been desired. The high resistance and high reaction of such an armature operate against its promptly delivering more current with slight increase in speed, since as soon as the current becomes nearly equal to the lamp load, a large armature loss from these two factors results, and the machine, which has been built particularly to give a low cut-in point has to have its speed raised inordinately in order to furnish the critical current at the minimum speed.

Factors that affect the minimum size of generator are the permissible heating and the permissible sparking at the brushes. The heating is proportional to the resistance and to the square of the current. Therefore, for larger currents we have to wind armatures with larger wire and if the number of turns is still the same as it is if the speed remains the same, then armatures that provide room for this larger wire, and consequently the whole machine, must be larger. As to the sparking at the brushes, this may be a determinating factor, but usually is not when the design of the machine is along the lines of low armature reaction without reference to early cut-in speed.

Passing now to the subject of starting motors, we utilize the tendency of a conductor lying in a magnetic field to move at right angles to its length when it is traversed by electric current. This force is proportional to the strength of the magnetic flux and to the value of the current. The characteristics required of starting motors are well met by making them series motors in which the entire current passes around and magnetizes the field before entering the armature. In such motors, if the iron did not become saturated with magnetic lines, the pull would increase proportionally to the magnetizing current and therefore to the flux, while the pull due to increased current in the conductor would increase due to this current alone, so that the resultant of increase both in flux and in current would produce a pull increasing as the square of the current. However, we have to deal with iron in which the magnetic flux does not increase proportionally to the current, on account of the iron becoming saturated, so that the pull of starting motors varies more nearly in direct proportion to the current over a large part of their useful range.

Starting Motors

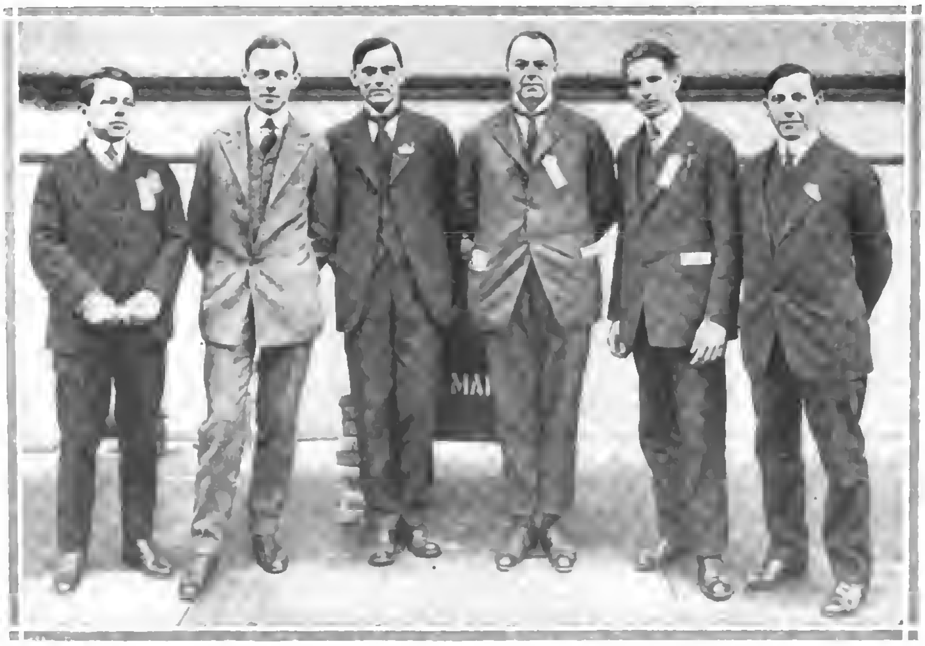
In general, for any given amount of horsepower required, the size of a motor diminishes as the permissible speed goes up, but at the same time many losses arise with speed, such for example as the loss due to friction of the brushes on the commutator, and the loss from the reversal of magnetism or hysteresis in the armature, and other losses due to stray or eddy currents in the armature conductors and in the faces of the magnetic poles. Where the work is large, it is often desirable to take advantage of the possibility of high speed by using a motor which, instead of acting on the flywheel direct, is geared-up so that the ratio between motor and engine shaft approximates 30 to 1, or even higher. However, where the engine is small and the work to be done less, the cost and extra parts of gearing are not warranted in view of the smaller and smaller saving to be made in the motor as its size goes down, and in view of relatively large losses in gearing and bearings, so that it has come about that geared-up motors are used to crank the larger engines, whereas for small engines, or for those for which less cranking ability is required, direct-acting motors are employed working with ratios in the neighborhood of 10 or 12 to 1. For such motors, it is desirable to have the ratio as high as possible in order to utilize the benefit of higher motor speed and so diminish motor size and cost, for which reason it is better to be able to use a ratio of 12 to 1 than one of 9 to 1; a motor employing the higher ratio would be about three-quarters as large as a motor employing the lower ratio.

The power required to crank an engine depends greatly on the temperature since as the temperature falls, the viscosity of the oil increases, offering much greater resistance to turning. Under the conditions that prevail at present, the prime requirements seem to be that the motor should be able to break the engine loose at whatever temperature is fixed upon as being reasonably low and that at this temperature it should be able to crank the engine fast enough to make ignition readily take place. Experience has shown that starting is not obtained as easily when the engine is turning over only say 12 r.p.m. as when it is being cranked at 60 r.p.m. This is for a variety of reasons, including the difficulty of drawing in the proper mixture at very low speeds and the excessive dissipation of the heat of compression at low speeds. Therefore the starting motor has to be proportioned with these conditions in mind.

If it is feasible to ascertain the torque on the crankshaft required to break the the engine loose, and if the torque required to keep it turning at a given temperature is also known, and if the ratio between motor and crankshaft is fixed, the adequacy of a motor can be determined. In fact, the relative performance of motors can be considered best by assuming that the torque required is the same and considering the other conditions which prevail at various values of torque. In most cases the torque is fixed by the engine and the possible gear ratio, and it is frequently known exactly or from comparison with other engines; in which case, if the motors can be compared on the basis of torque, the performance of motors in connection with the engine can be closely predicted, and the relative qualities of motors more easily determined.

Characteristics of Starting Motor

A convenient chart for comparing motor action is shown in Fig. 1, which has the results from a certain motor plotted on it. On this chart the abscissae are the values of torque in pounds-feet and the ordinates the revolutions per minute of the electric motor. On the same chart other ordinates are laid out. The column on the left immediately next to the column of speed relates to brake-horsepower. The next column relates to volts measured at the motor terminals. The next column refers to the electrical efficiency of the motor when converting electrical into mechanical power. The right-hand column relates to amperes. To further explain this chart, the speed of this particular motor when it had a pull or torque of 2 lb.-ft. was 1600 revolutions and with double the torque, or 4 lb.-ft., the speed dropped to 1140 revolutions. At 6 lb.-ft., the speed was 910 revolutions and at 16 lb.-ft., dropped to 260.



Section Secretaries of S. A. E. From Left—W. H. Conant, Detroit—B. B. Bachman, Pennsylvania—R. C. Combs, Indiana—Coker F. Clarkson, General Manager S. A. E.—J. E. Schipper, Metropolitan—D. S. Hatch, Mid-West

The value of the volts at the motor terminals and the other data corresponding to these torques are shown by the remaining curves. Thus, for the torque of 8 lb.-ft., where the speed is 740 revolutions, the amperes, by referring to the proper column, are 280, the horsepower is 1.13, the efficiency 57 per cent and the volts at the motor terminals when this torque reading was obtained, were 5.15. In connection with this latter, it has been found useful to approximate in these tests the voltage at the motor terminals which prevails on automobiles under service conditions. There will, of course, be some difference according to conditions of tests, but a comparison between motors can be made if these conditions are assumed at approximately sensible values.

The motors are tested with the voltage at the terminals regulated to lower and lower values as the current rises. The following table will serve to indicate the voltage that can often be expected at the motor with various values of current flowing into it. The reason for the increasing drop with rising current has been referred to in considering the storage battery, and to the battery drop there must be added the increasing voltage loss in the leads and connections between battery and motor.

Amperes Into Motor	Volts Assumed to be Maintained at Motor Terminals
30–40	6
100	5.7
150	5.6
200	5.4
300	5.1
400	4.8
500	4.4
600	4.0
700	3.5

Similarly, the performance of another direct-acting motor of smaller size is shown in Fig. 2. Considering the larger motor, as shown in Fig. 1, the highest torque obtainable is 21.8 lb.-ft. with 630 amp., which flow as a result of 3.6 volts across the motor terminals. In other words, the locked torque is 21.8 lb.-ft. Assuming a gear ratio of 12 to 1, this corresponds to a torque of 262 lb.-ft. on the crankshaft to break it loose. If we assume that around 60 revolutions is the lowest point at which starting will take place readily, then on the curve we look for about 720 revolutions of motor speed and find that the motor speed drops to 740 when the torque rises to 8 lb.-ft. In other words, this motor will develop 96 lb.-ft. at the crankshaft before the engine revolutions drop below 62.

Cranking Torque and Speed

The torque needed to crank in cold weather may often be taken as about three times the torque required under ordinary conditions (around 70 deg. Fahr.), and if it is desired to provide for extreme cold, an assumption that the torque will be four times as great is usually not far from correct. Making this latter assumption, if the torque for the slower cranking was 8 lb.-ft., then the normal torque would be 2 lb.-ft., corresponding to a motor speed of 1610, or with a ratio of 12 to 1, about 134 crankshaft revolutions.

Putting the matter in a different order, we find that this motor when geared 12 to 1 would perform about as follows: Applying 24 lb.-ft. on the crankshaft it will spin the engine at the rate of 134 revolutions with a current of 108 amp., if the volts across the motor terminals are 5.7. At four times this torque, developing 96 lb.-ft. on the crankshaft, it will crank the engine 61½ revolutions, taking 280 amp., if the volts at the motor are 5.15; and before it can be stalled, it will apply 262 lb.-ft. on the crankshaft to break loose a cold engine.

Torque and Current

To grasp readily the difference between a large and a small motor, or rather to see readily what sacrifices are made as the motor is made smaller and cheaper, we will assume that the smaller motor is applied instead of the larger one, all other things being left the same. The gear ratio, which we would like to have increased above 12 to 1, cannot be increased by merely making the motor smaller, since the gear ratio is usually dependent on the size of the flywheel gear compared to the motor pinion and is not affected by the motor size. Examining the curves of the small motor (Fig. 2) and taking the same values of torque, we find that it will develop 24 lb.-ft. on the crankshaft with a cranking speed of 1880 ÷ 12 = 157, using 160 amp., if a voltage of 5.6 is maintained at the motor terminals. For a crankshaft torque over 96 lb.-ft. it is entirely inadequate, and assuming the curve of revolutions to be prolonged, it would crank with a speed of about 324 ÷ 12 = 27 engine revolutions, with a current of 435 amp., if 4.6 volts were maintained at the motor terminals. Before the engine stalls, it will develop on the crankshaft 11.6 × 12, or about 140 lb.-ft. to break the engine loose.

We see from this comparison that the little motor would actually crank the free-running engine in a moderate temperature, when the torque was 24 lb.-ft., faster than the large motor, but this is now shown to be no indication whatsoever of what the cranking will be in cooler weather. In order to do the cranking under easy conditions, the small motor uses considerably more current than the large motor. The small motor performance falls away down as the load rises; the motor is incapable of exerting anywhere near the breaking loose effort afforded by the larger motor.

A further comparison between large and small motors can be made as in Fig. 3, where I have superimposed the curves showing revolutions, amperes and horsepower, but omitted the curves of efficiency and voltage to avoid confusion. On Fig. 3 the curve for the large motor is shown in full lines and the curve for the small motor in dotted lines. One of the first things we notice is that for all torques the current used by the small motor is greater than the current used by the large motor. Another point is that the locked or stalled torque of the large motor is about twice that of the small motor. Looking at the horsepower curve we see that the small motor exerts its greatest horsepower when its torque is about 5 lb.-ft.; whereas the large motor exerts the maximum horsepower at nearly twice this torque, or 10 lb.-ft. As far as speed is concerned, cranking by the small motor is faster than that by the large motor when the torque is less than 4½ lb.-ft., or 54 lb.-ft. on the crankshaft, but for torque beyond this, the large motor is far superior, and if the critical speed of cranking is taken at 50 revolutions, which is a commonly used value, the small motor will sustain this speed so long as the cranking effort does not exceed 6½ × 12, or 78 lb.-ft.; whereas the larger motor will crank faster than 50 r.p.m. until the cranking effort has risen to 10 × 12, or 120 lb.-ft.

In connection with these curves, it may be noted that in most cases, until the size of the motor is forced down to the smallest possible, the locked torque is usually not the limiting factor, if the condition for cranking a cold motor at adequate speed has been met; that is to say, any motor which will crank fast enough with a reasonable current consumption under cold weather conditions, usually has sufficient locked torque to break the gas engine loose. Of course this is only a generalization and does not always apply. In practice, it has been the speed of cranking in cold weather that has limited the size of the motor in most cases, rather than the ability to break loose.

Determining Motor Size

With curves plotted in this manner, it is a comparatively short undertaking to determine the smallest motor that will meet any conditions laid down, as a cranking test can be made on the engine with any motor, although preferably with one about the size likely to be used. From this test the cranking torque of the gas engine is determined and the probable cold weather torque anticipated, and from these data a motor of the minimum size can be selected or designed with tolerable accuracy.

Single-Unit and Two-Unit Systems

If the operation of the two-unit system is clear, the functioning of a single-unit system will be understood more easily. I am referring now only to the simplest of the single-unit systems, in which we have a motor-generator directly connected to the crankshaft with a ratio of about 3 to 1, usually through a silent chain. Not only is the motor-generator driven at about twice the speed at which an ordinary generator would be used, but it is a large machine whose armature has larger inertia and whose drive is subjected to considerable strains in cranking which do not occur when the drive is to a generator alone. The reason for the high ratio is that a machine of this kind needs, as a motor, as high a ratio as it is feasible to obtain. We have already seen in the consideration of the two-unit systems that the generator is suitably driven from many engines when its speed is 1½ times crankshaft speed, whereas the motor is well geared when its ratio is about 12 to 1. It is, therefore, obvious that in the motor-generator we tend to gear it higher than the generator, which accounts for the fact that it should run at about three times crankshaft speed.

It is characteristic of single-unit systems that for cranking they usually develop a lower locked torque on the crankshaft as compared with the same weight of apparatus arranged in the two-unit system. For equal weights, the single-unit system while somewhat deficient in the locked torque, is also somewhat lacking in ability to crank a cold motor around 60 revolutions, but the difference between the single-unit and two-unit systems is not as great as generally supposed.

It is characteristic of the single-unit system, operating with constant engine ratio and with only one armature winding, that it is most efficiently operated at 12 volts; whereas the two-unit system is perfectly satisfactory at 6 volts. A large part of this difference is due to the characteristics of the brushes required for good operation as a generator, which must also serve as motor brushes when the machine is cranking; whereas with the two-unit system the motor can be designed without any reference to the generator, and thus adequate provision made to keep the losses small on a 6-volt system.

In discussing Mr. Bijur's paper several of the members commented on the fact that the voltage regulation should be sufficient. It was pointed out that a lighting concern would be put out of business by the public service commission if a variation in voltage amounted to 5 per cent. Good results, it was said, cannot be expected without constant voltage. It is a difficult matter to exactly regulate voltage, but this regulation should be attained if possible.

H. W. Slawson asked what would happen to the battery due to a continuous overcharge. To this L. B. Brown replied that while he could not give any exact information he thought that it would be possible to get it from the Delco men who had abandoned the ampere hour meter and could probably tell why. Mr. Kettering of the Delco company said that while the ampere hour meter was good in its way and did the work he knew of one instance in which the engineer had cut off its hands. He further stated that if it were not for the different kinds of drivers the entire work of design would be easy.

A. D. Libby made a plea for smaller units. During the past year the electrical equipment on our cars has been becoming larger. Mr. Libby said that he had made some tests in which he had reduced the lamp load from 7 amp. to 3 and secured twice as much illumination. The loads can be reduced, he said, and therefore the cost merely by efficient design, proper focusing, etc.

Safety Control for Electric Vehicles

SAFETY is sometimes better secured by engineering than by legislation. By a simple change in the control mechanism of all its electric trucks, the department of welfare and safety of the Eastman Kodak Co., Rochester, N. Y., has effected an infallible safeguard against the cause of many serious accidents.

The illustrations show one of the devices mounted in a box similar to a driver's seat in the rough. The driver sits at the left side of the box, operating the control lever with his left hand. The rheostat selector shaft, to which the controller lever is attached, also carries a sector which prevents the operator from engaging the switch except when the selector is at the neutral point. A lever has been attached to the main switch from which the handle has been removed and this lever has a pawl while there is a slot in the sector through which the pawl on the lever actuating the switch must pass in order to close the switch. The sector is so located that when the switch is closed, the rheostat selectors are all at the neutral point. As the pawl is held forward by a pressure spring, the switch lever can disengage the switch at any position of the selector.

Starting with the controller lever at neutral and the switch open, as in Fig. 1, the switch may be closed, as in Fig. 2, the pawl slipping through the slot in the sector, and passing clear through so that the controller may be moved to any desired notch. If the switch be opened, say in one of the reverse notches, as in Fig. 3, it cannot again be closed until the controller lever has been moved to neutral position.

The Rostrum

Fitting Flanders Camshaft Bearings

Editor THE AUTOMOBILE:—The following questions are relative to a Flanders 20 model 1912, motor 3⅝ by 3¾, L-head centrifugal water pump.

1—Can aluminum alloy pistons be used to advantage on this car? If so, what clearance should they have?

2—Would you advise using the hour-glass type or the wiper-ring type as used on the King? This car uses four rings, one of which is a wiper, the oil system being the vacuum splash. Would you use the same number of rings as on the cast iron piston?

3—Will the additional clearance for alloy pistons cause much oil pumping, at low speeds, without a wiper ring?

4—Can a slightly scored cylinder be repaired without being rebored?

5—I want to fit new camshaft bearings, middle and rear end. I have an old camshaft and would like to know if it would be practical to lathe off say 0.002 in. of these bearings of the old shaft and cast bearings from Fahrig metal right into place. Of course the middle bearing would have to be cast split so that it could be removed, scraped and replaced with the new shaft.

Stephens City, Va. E. E. C.

—It is doubtful if the introduction of aluminum alloy pistons to a model as old as this would be justified. There are so many other features of design which govern the speed of a motor that the use of aluminum pistons in a motor of 1912 would not have any appreciable effect.

2—This is answered under question 1.

3—While the initial clearance of alloy pistons is greater than that with cast iron the greater expansion of the aluminum soon compensates for this. The number of rings would be about the same as on the cast iron type.

4—A slightly scored cylinder can be remedied by lapping or grinding.

5—New bearings can be cast in place, but this is a job which requires skill and practice.

Racing Records Held by Oldfield

Editor THE AUTOMOBILE:—Kindly give me the records held by Barney Oldfield and officially allowed by the contest board of the American Automobile Association.

Yonkers, N. Y. C. W. L.

—The following tabulation gives the records held by Barney Oldfield to date:

Speedway Records Regardless of Class

20 miles	—13:58.14	Oldfield	Stutz	Indianapolis, May 30-14
25 miles	—17:30.40	Oldfield	Stutz	Indianapolis, May 30-14
5 miles	— 4:01.36	Oldfield	Knox	Indianapolis, May 30-10
5 miles	— 3:38.61	Oldfield	Knox	Los Angeles, Apr. 16-10
10 miles	— 7:20.66	Oldfield	Knox	Los Angeles, Apr. 16-10
1 mile	— 40.53	Oldfield	Benz	Daytona, March 16-10

Firing Orders of Typical Twelves

Editor THE AUTOMOBILE:—Please publish the firing order of a few of the standard twelve-cylinder motors.

Richmond, Ind. R. N. L.

—The firing order of the Packard twin six is 1R-6L-4R-3L-2R-5L-6R-1L-3R-4L-5R-2L. The letters R and L refer to right and left cylinder block, respectively.

The firing order of the National twelve is 1R-6L-5R-2L-3R-4L-6R-1L-2R-5L-4R-3L.

The firing order on the Enger is 1R-1L-5R-5L-3R-3L-6R-6L-2R-2L-4R-4L.

For your further information the firing diagram of the Pathfinder twin six is given in Fig. 1.

Finding Corresponding Gear Teeth

Editor THE AUTOMOBILE:—Kindly give me the formula for figuring the number of revolutions a gear must be turned to bring corresponding tooth marks together on timing gears set with odd teeth.

2—What causes end play in a crankshaft to develop?

3—What cause can be attributed to the Remy magneto used on Buicks in 1910 and 1912 making the engine fire on only two cylinders? Is it advisable to grind the worn cam down?

Watsonville, Cal. A. W. A.

—The method of figuring the number of revolutions a gear must turn to bring corresponding tooth marks together on timing gears set with odd teeth is simply to calculate the least common multiple of the numbers of teeth on each wheel. For instance, if one wheel has sixteen teeth and the other has ten teeth the least common multiple would be 80. Then for every eight revolutions of the ten-tooth wheel or five revolutions of the sixteen-tooth wheel the same teeth would come into mesh.

2—End play in the crankshaft is very often due to thrust by the clutch springs. It may also be due to the mis-alignment of the pistons and connecting-rods.

3—It very often happens that a cam will wear in one point only and it is quite evident that you have a case of this kind. Since the shape of the cam determined the synchronism of the magneto and since special machinery is necessary to get the proper face angles on the cam, the cam itself should be replaced with one of the standard Remy cams.

Determining Area of Poppet Valves

Editor THE AUTOMOBILE:—How is the valve area determined in a poppet valve, having the two diameters given; also, the lift.

2—What is the co-efficient of friction used in designing a poppet valve?

3—Of a Knight type valve?

4—How is the inertia of the reciprocating parts of a motor calculated?

5—How is the velocity of the gas in the intake and exhaust pipes determined?

6—Why should counterweights on crankshafts be placed in the same planes that the crank throw is in?

7—What is the critical speed of crankshafts? How is it determined?

8—What is a harmonic vibration?

Frankfort, Ind. T. S. W.

—By valve area it is presumed you mean the area of actual opening. The area through which the gas passes is the surface of a truncated cone. Referring to Fig. 1, let the sketch represent an ordinary 45 deg. poppet valve. The truncated cone is that bounded by the edges *D A* and *D' A'*. The area of the surface is then the quantity desired as the two diameters you mention are *DD'* and *AA'* and the lift is *DB*.

$AD = BD \cos 45$ deg. or, $AD = .707\ BD$.

The area of the truncated cone will be *AD* multiplied by the mean diameter or $\frac{DD' + AA'}{2}$ times π. The expression for area then becomes by substituting:

$\text{Area} = \pi\ (.707\ DD' \times DB + .353\ DB^2)$

If *h* be the symbol for the valve lift and *d* the symbol for the clear diameter the expression for area for a 45 deg. valve becomes:

$A = \pi\ (.707\ d\,h + .353\ h^2)$

2—The coefficient of friction is only taken into account in an empirical manner.

3—This is also empirical.

4—The inertia is calculated by the ordinary formulae for energy in mechanics.

4—Inertia of any moving part can be calculated by the basic inertia formula for acceleration. In other words, acceleration is the act of overcoming inertia and it is expressed as the change of velocity which takes place in a unit of time. Where *F* is acceleration, *M* the mass of a body, *V* the velocity and *T* the time, *F* is equal to *MV* divided by *T*. However, in designing the motor it is just taken for granted that the inertia of the reciprocating part will be at a minimum when the weights are at a minimum and hence every effort is made to keep the weights low.

5—The velocity in the manifolds is calculated by dividing the volume of flow by the area of the passage, and the volume is determined by the displacement per unit of time multiplied by a factor which takes into account the volumetric efficiency.

6—This is by no means always the case and depends entirely on the individual system of balance employed.

7—The critical speed of a crankshaft is the point at which vibration due to speed commences. It is determined experimentally.

8—The term harmonic signifies a connection with sound and connected with the word vibration signifies a rate of vibration which is a multiple of the fundamental note. The pitch of the note varies with the period and amplitude of vibration.

Regulation of the Heinze Generator

Editor THE AUTOMOBILE:—Will you give a circuit diagram of the voltage regulator and connections as used in the Heinze generator 1916?

2—Do any other systems other than the Westinghouse, Bosch, Heinze and Bijur use voltage regulators? If so, give names and are they of the vibrating contact type?

3—Are the Leece-Neville and Wagner 1916 systems using third brush regulation? Has Bosch done away with using the pole pieces to draw in the armature and now using a piece of iron on the armature and a separate coil for this operation and do the Bosch still short the armature on the meshing contact of the starting switch?

4—Why is the positive shunt lead carried all the way to the battery instead of grounded on the Bijur system on 1915 Scripps-Booth?

Newark, N. J. R. J.

—The circuit diagram of the voltage regulator and connections in the Heinze 1916 generator is shown in Fig. 1. Wire *A* connects to the generator field, the other end of the generator field being grounded to the frame of the generator. The negative brush is also grounded, this being a single wire system.

Wire *B* connects to the ground, this being the outer end of the potential winding, the inner end of this same winding connects to the regulator cut-out magnet frame, which is insulated from the grounded frame of the generator.

Wire *D* is the outer end of the current winding and connects to the positive lead of the storage battery, the inner end of this winding connects to the contact shown on the cutout side.

Wire *C* from the regulator cutout magnet frame connects through the generator switch to the positive brush of the generator. The generator switch is a part of the main switch on the dash, and is so arranged as to break this circuit when the starting button is depressed.

2—All electrical systems on cars have a means of regulating the voltage. In some this method is inherent with the machine due to the type of winding. In others there are exterior means. At any rate every complete system must have voltage regulation.

3—The Leece-Neville system is regulated by the third brush method, and the Wagner also employs the same system. The Bosch company has not done away with the construction in the flywheel starter, that causes the armature to be drawn into the electrical center through the magnetic influence of pole pieces. The Bosch company does not short the armature when the gears come into mesh but through the use of a shunt table the current in the armature is limited and not shorted.

4—The wiring diagram for the Scripps-Booth is shown in Fig. A for all cars numbered from 1 to 1100. Fig. B shows the wiring diagram for cars numbered above 1100.

Referring to Fig. A the shunt field lead is carried to the positive battery terminal instead of being grounded direct, so that removing the storage battery opens the shunt field circuit of the motor generator, which prevents any damage to this machine in case the gas motor is operated without the battery.

The starting switch shown in Fig. B has three positions, On, Off and Idle, and the field circuit of the motor generator is broken through this switch when the switch is moved to the Idle position, which would be the normal operating position when running the car without the storage battery.

Switches on cars from 1 to 1100 inclusive were not provided with the Idle position, hence the necessity of carrying the shunt field lead back to the positive of the storage battery.

The History of the American Automobile Industry—13

Steam Vehicles in England, 1860 to 1870, Immediately Before the Invention of the Flash Generator in France, which was Responsible for the Great Modern Development in Steam

By David Beecroft

WE now come to the last few years preceding the modern movement for the development of steam vehicles in France, associated with such names as Bollee, Serpollet, and DeDion Bouton, around which clusters the inventions which brought steam into the prominence it obtained in Europe and America until a few years ago. This group was responsible for the flash boiler design which was so extensively used in this country by the White company. Before proceeding with this great development of the flash generator some of the developments in England and Scotland between 1860 and 1870 are of interest as showing the development made in these countries in spite of the handicap of road laws which made operating vehicles on the road practically impossible.

At the exhibition of 1862 were shown automobiles by Yarrow & Hilditch and also by Tangyes of Birmingham. The former had a vertical tubular boiler and a separate engine for each wheel. It would carry thirteen people and weighed 5000 lb. The latter used a very similar engine arrangement. In the same year A. Patterson built a carriage having the boiler and engine both mounted on the front wheels which served for steering and propelling.

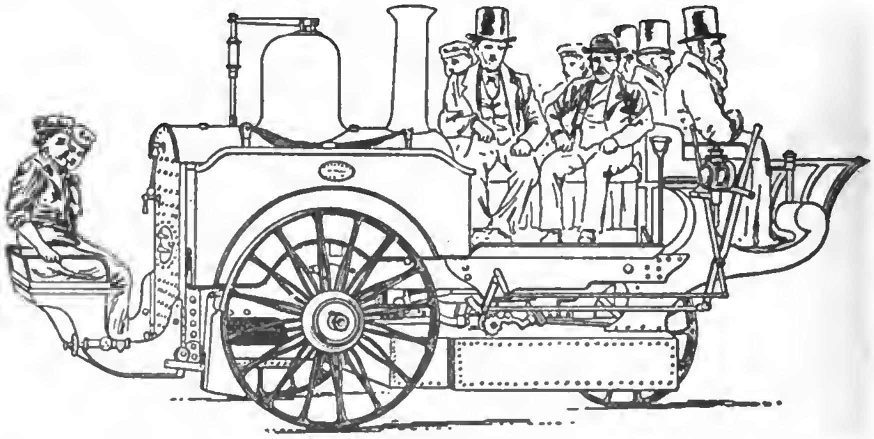
A steam super-heater was used on the wagonette of Catley & Ayres of York, built in 1869, and frequently used, carrying four people. It weighed 1500 lb. empty, and could run 20 m.p.h.

About 1870 several Scotch engineers took up the work and produced vehicles, but the most successful seems to have been the road steamers of R. W. Thompson, the inventor of the air tire some 25 years before. His vehicles were fitted with solid rubber tires as much as 6 in. thick by 12 in. wide, and these splendid road smoothers doubtless had much to do with the satisfaction given by these goods. They were sold in India, America and other places for hauling omnibuses and similar work.

L. J. Todd of Leith, Scotland, built several steam vehicles between 1869 and '72. One of these was a light carriage, having three wheels, and each rear wheel driven by a belt from its engine. Nairn, also of Leith, made a three-cylinder omnibus in 1871, which carried 50 passengers and weighed 10 tons loaded. He seems to have used a rope tire to deaden shocks.

A Scotch Experiment

In 1873 Charles Randolph of Glasgow built a very successful vehicle having the operator's cab at the front, a coach body at the center and mechanism with stoker's compartment at the rear. Its capacity was ten people; its speed about 6 m.p.h., and its weight loaded over 4 tons. He used a vertical coal fed boiler and discharged the exhaust into a silencer from which it passed to the smoke stack and thus no steam could be seen. Elliptic front and coil rear springs were used. Although it worked successfully and the authorities shut their eyes at his violations of the law it proved to be something of a white elephant and after being unable to sell it he turned it over to the South Kensington museum. There were a number of others, but all working along much the same lines and meeting the same obstacles.



One of the interesting steam road vehicles shown at the exhibition of 1862 in England was developed by W. O. Carrett of the firm of Carrett, Marshall & Co., Leeds. This vehicle had an interesting history in that it was run approximately 800 miles at night over the roads of Kent, in order to get some use of the highways in spite of the road laws which prevented the use of motor vehicles on them. It was christened the Fly-by-night and was summoned many times for violations of the locomotives act. It bore a strong resemblance to a fire engine and at night the passengers were dressed as firemen with brass helmets. In this way it was possible to escape much interference, but later it was impossible to use it on the highways and it was finally converted into a slow-moving engine. It was made with three wheels and used a locomotive type boiler adapted to stand 175-lb. pressure per square inch. It incorporated a two-cylinder engine which was geared to the rear axle. The axle had the usual differential gear. The vehicle weighed 12,000 lb.

Light Weight as an Ideal in the Designing of Large Cars

A Sequence of Facts and Reflections on Both Sides of the Question—By M. C. K.

AT one time, about 1901, when European cars were immeasurably superior to American cars in nearly all essentials, the American public and industry were stampeded into a somewhat uncritical adoption of the European type of car but soon took sharp distance from the European methods of producing it. Numerous technical details have come across the water since that day and usually have been found worth studying with a view to modification and adoption in the modified form. The high-speed motor represents the latest large wave of technical reform coming over here with strong European endorsement (practically unanimous up to about 2400 r.p.m. or about 1200 ft. piston speed with a stroke of 6 in.) and it has been accompanied in Europe by a considerable effort for reducing the weight of cars. Arrived to these shores the high-speed motor movement with its accompanying demand for lightness—to help in fuel economy and compensate for the weight of lighting and self-starter equipment—has met great hospitality but has encountered a popular reluctance against the frequency of gear-changes which so far has been found necessary with light motors and which of course is more in evidence the more difficult the road conditions are.

In this situation the various factors are yet to be adjusted to American demands. It is not yet quite settled what the normal speed of motors had better be, whether lightness of cars should be accomplished at all costs, or whether, as a rule, we had better strike a medium in stroke length, piston speed, motor size and car weights. To be again stampeded into a complete imitation of the European development, when it is a fact that the most successful European manufacturers have followed it only in part and with great reserve, and when nearly all the practical conditions in America are different, does not recommend itself as the most sensible proceeding at this advanced stage. One of the factors in question, the light weight of cars, especially invites analysis, because its appeal escapes all criticism in theory and leaves it in doubt only to what extent such lightness may be reconciled with other requirements in practice and to what extent it is likely to be economically valuable in the future. That the lightness should always be as pronounced as all due consideration for other car factors will permit—cost of production, strength, anti-fatigue quality, rigidity where wanted, road ability, durability, efficiency of lubrication, etc.—is so nearly self-evident that lightness may easily become accepted as an ideal for car construction if public opinion accepts it as such without viewing the subject from many other angles than that of the conspicuous and popular advantages. It is the object here to let some of these other related ideas file in review before the reader, to produce, so to say, a perspective and a cross-section of the possibilities for light car construction rather than merely front and plan projections.

Lightness by Reduced Size Came First

For more than ten years past the average car both in Europe and America has been getting heavier, with corresponding increase in tire, oil and gasoline bills. During the same period upkeep expense has gone down, repairs getting much lighter and cheaper with improved construction. But the operating expense—mainly for tires, fuel, oil and garage—became more onerous in the measure as cars were used more and more by the less wealthy. The wages of chauffeurs can here be ignored. The remedy for the economical burden has been sought and found very generally in small cars, in which the weight is escaped through reduction of the size. The much lower first cost pointed the way in this direction unmistakably. In some of these small cars the driving speed was also reduced, but in the most successful case on record, the Ford car, the weight reduction due to small dimensions was very much accentuated by using a new grade of steel throughout, while the driving speed and its indirect cost were practically left at the car owner's discretion. It was low-priced and cheap to run long before methods for its production were developed which increased the profits to the makers, and it is still a good example of lightness due to design as well as to small size. In general the small car, spite of diminished luxury, was found suitable—first here and subsequently in Europe—for many people's daily use of a vehicle. Still, the large car remains a necessity for as many others, and it remains heavy; heavier in 1915 than in 1905—costlier to operate though cheaper to keep in condition for operation. Only a few manufacturers of the larger cars have from the beginning aimed constantly at reducing the operating cost by minimizing the weight, and the very general adoption of alloy steels for parts subject to wear or special stress has had only a feeble tendency to prevent the gradual and apparently unavoidable increase of total weight from becoming excessive.

"Life" Largely a Carbureter Question

Now, under the pressure of the demand for economy and efficiency, the difficult problem of making large cars light is rather suddenly coming to the front. As said, it has come in conjunction with a demand for light, high-speed motors. The need of producing a car which can be accelerated promptly by the throttle alone, although the motor has small cylinder volume, may have had as much to do with the desire for reducing the weight of the whole car as the view to operating economy. It would scarcely do to let small cars with relatively sluggish motors have an advantage in acceleration over their larger and more pretentious sisters, since prompt acceleration or "life" is one of the luxuries on the road which is appreciated as much in a motor as in a horse by the American public. On the other hand, to accept in advance the conclusion that reduction of vehicle weight represents the simplest and best method for getting prompt acceleration for a car equipped with a light motor is not convincingly clever so long as little effort has been made to find out if a similar result could not be attained by simpler means, such as, for example, by an auxiliary carbureter action.

Among the carbureters found most suitable for high motor speed it is hard to think of any that does not necessarily, by its principle of design, make acceleration more gradual than the exacting car driver would like it to be. He is more interested in what the car will do in the first second after the throttle has been opened than in any ability to accelerate from 10 to 40 miles per hour in 16 seconds, which is about the best that can be done with a car of average weight for its power and a carbureter action depending mainly upon an increased volumetric efficiency at the opening of the throttle for gradually producing the higher motor speed with the stronger suction at the nozzles which in turn will speed the fuel feed and the motor progressively. This system of acceleration—falling far short of steam throttle promptness—is too indirect for a heavy car, although it is sufficient for one that is light and strongly powered. It is slightly assisted in practice by opening wide first and moderating a few seconds later, but this can only be done with high-class gasoline, so long as the cooling-system fails to keep motors at a uniform temperature at all speeds. For the moment the possibilities for an improvement at this point which might eliminate the need of weight reduction for the mere purpose of facilitating acceleration may be conceived in the form of an injector attached to the carbureter conduit and operating automatically, for a second or two, with small stores of compressed air and gasoline, whenever the throttle is being opened, the extra injection compensating for the anomaly that, with ordinary carbureter action, the relatively weak suction of the lower motor speed necessarily causes the first explosions after the turning of the throttle valve to be weaker than the subsequent ones. Without pretending to say that the suggested boosting device, or one of equivalent effect, is advisable, one can safely infer from its possibility and from its simplicity in comparison with weight reduction that the popular demand for prompt acceleration does not in itself constitute a compelling reason for undertaking a radical reduction of the total weight of the vehicle, so long as simpler means to the same end are not adopted.

The active reason for undertaking such a weight-reducing campaign must therefore be the economical one of reducing operating expenses. The better acceleration of the lighter car can only be an incidental advantage, and this is perhaps also the usual view. The main facts are admitted; namely, that a desire has become general among American manufacturers for reducing the weight of cars, while holding the size of motors down, and that the economy in tire, fuel and oil expenses gained by such weight reduction has been abundantly proved. THE AUTOMOBILE said editorially in the issue of Dec. 23: "Light weight is the greatest factor in reducing the upkeep and so is of immense importance to the owner." Before long, since ideas travel fast when plainly containing a large element of truth, this view may become accepted as an axiom and may be taken to cover the whole field of constructive varieties of automobiles. And, on the other hand, the majority of engineers and manufacturers will probably not see their way clear to any considerable reduction of the weight of their cars and will be able to present excellent reasons for not allowing construction to be dominated by the consideration of minimum operating cost.

Broader Paths to Economy

At first glance one would be inclined to say that, if the object of light weight is economy, it should be materialized economically and without increase in the first cost of production, but it is of course a simple financial question of capital and interest which is here involved. The saving in upkeep due to light weight may be large enough to justify a higher first cost, and the incidental advantages of quick responsiveness to the throttle, to gear change and to the touch of the pilot's hand on the steering wheel—as well as a probability for less bother with tire troubles—may be sufficient to place the light-weight large car in a class by itself, a class where high price and high merit go together until the light-weight design and construction become standardized, or at least fully established to the satisfaction of the manufacturer and his customers, whereafter the price may become normal while all the special merit remains, unless the rest of the industry meanwhile has learned to produce equal merits by other means. IT IS CONCEIVABLE THAT CARS MAY BE CONSTRUCTED WHICH ARE NECESSARILY HEAVIER THAN THE LIGHT-WEIGHT IDEAL BUT POSSESS ALL ITS ADVANTAGES ON THE ROAD AND IN ECONOMY OF UPKEEP WHILE POSSIBLY BEING ALSO MORE CHEAPLY PRODUCED OR LESS SUBJECT TO FLAWS DUE TO ERRORS IN THE APPLICATION OF THE PRODUCTIVE METHODS. With regard to the last point, all remember, for example, the time when a large percentage of cars from certain factories went wrong through the failure of light component parts which had not been properly heat-treated or were made of unsuitable steel or were too closely designed and succumbed to fatigue or lack of rigidity. Most steel troubles are over—mainly because conservatism and specialization are in command of the metallurgical departments of automobile and parts factories—but light-weight design still requires the tip-top of ability and experience if it shall afford the same guarantees for the avoidance of troubles which have been worked out with standard types of construction through the collective efforts and experience of the industry.

In order to keep very sharply in mind where a complete acceptance of the ideal of light-weight construction for large cars leads to, it is necessary to compare with other means at disposal for accomplishing the same or a similar degree of upkeep economy and "road ability" and to face the fact that such other means may be widely applicable to all sorts of motor vehicles, while nearly all the advantages of light-weight construction of a vehicle disappear if the vehicle is required to carry heavy loads.

Operating Cost and Total Upkeep Expense

A distinction between operating cost and upkeep cost is among the first ideas suggesting themselves when the subject is analyzed. As a rule the term "upkeep cost" is used to cover the whole expense of keeping and using an automobile, once it is paid for. But, while it is proved sufficiently that the light car can be driven more cheaply than the heavy one—so long as the question is of two cars of about equal grade and both weighing more than about 1500 lbs.—and can be kept tire-shod more cheaply, it is not nearly so well proved that it can also in other respects be kept in commission more cheaply, general durability and repairs being in doubt. The actual weight of the average car, being the result of an evolution and a process of survival, in which the pros and cons relating to dimensions, materials and shapes have come up for consideration many a time, argues in the opposite sense. Indeed, the new art of building light cars, in the sizes which so far have been heavy, consists perhaps mainly in applying very close reasoning and experimentation to the finding of new constructive expedients which will permit the weight reduction without endangering durability and increasing the upkeep expense. In other words, the acknowledged risk in undertaking to lighten construction is that the upkeep expense depending upon liability to trouble and repairs may be increased more than the operating expense is reduced. The ideas advanced by Mr. Brush on frame and running-board design, the details of the new Marmon car, the Chandler, the Fergus car, the broader adoption of aluminum alloys, compared, for example, with the means employed for a number of years to make the Franklin cars lighter than other cars of equal size and power, can scarcely fail to convey the belief that it is no easy matter to reduce weight without increasing maintenance expense, unless some of the standard organs of the average automobile are omitted (all the water-cooling organs in the Franklin) and chrome-steel and aluminum are used throughout in closely studied shapes.

While there is no doubt that weights can be reduced SOMEWHAT without great or lasting increase in the cost of production and with economical benefit with regard to the entire upkeep and operating expense, it seems equally certain that RADICAL light-weight construction must for the present remain a difficult specialty, with the economical advantages depending strictly upon the individual engineering ability devoted to it and the production facilities behind it. Radical light-weight construction is new construction and cannot be inaugurated to-day and materialized next summer without exposing both maker and buyer to risks.

Any argument based upon the pounding to which a car is subject on the road (with the severity supposedly in proportion to its weight) applies without fail to the wear and tear and sizes of tires, but loses in force when applied to the mechanical construction, just because tires and springs temper the shocks and usually temper them most effectively in heavy cars. A better point for the light-weight construction relates to the lubrication. If bearing areas are not reduced with the weight, the specific pressures are reduced and the lubricating oil gets a better chance to perform its saving function, being neither squeezed out or heated unduly. That bearing areas should not be reduced in light-weight large cars, to correspond with the normal reduction of pressures, follows from the experience alone that every car, and especially every large car, is liable to be overloaded to its full volume-capacity occasionally.

Light Car Results by Other Means

Assuming, in accordance with the foregoing, that the principal inducement for undertaking radical light-weight construction lies in the economy and responsiveness in the operation of the car to be accomplished by it (while the upkeep economy as a whole must remain in doubt until proved in each case), the manufacturer may contemplate other means for attaining the same advantages, while combining them with the safety of conservative design and with a wider application of the type of chassis produced. If he placed a limousine body on a light-weight chassis, he would not have much left of operating economy and responsiveness based on light weight. He prefers to gain economy also for those cars in his output which are to be heavily equipped. Suppose that he aims to cut down the weight of the open touring car conservatively—say 10 per cent for the chassis and all he possibly can for the body—doing this by improved design and not by paring down dimensions and also reducing the factor of safety. He can then choose a motor of slightly larger cylinder volume than would be needed for a car of still lighter weight, and can from this larger motor get the desired responsiveness of the car, but the fuel and oil consumption will be a little higher. A special study in carbureters, as referred to above (and giving such results as are said to have been accomplished by one of the prominent Detroit companies) will place his car on an equality with the very light construction, so far as responsiveness is concerned. The fuel consumption may or may not be larger, depending upon his degree of success with the carbureter, similarly as light-weight success depends on an unfailing ability to provide against slips in design, materials and workmanship. At worst he has an economical margin against him for fuel, oil and tires, while being even on acceleration and ahead on safety against repair bills and usefulness of his chassis for several kinds of body and load. The margin against him he can make up in any manner that will produce a corresponding saving in operating cost. He can save lubricant on the plan so capably organized in the Fergus car. Outside of the cylinders more oil is ordinarily wasted than is used. By arranging to oil every six months only, the waste is stopped, damage from failing to lubricate is stopped and work is reduced—all items of economical value. He can design his slightly larger motor with a slightly larger cylinder bore than that used for the motor in the radically light-weight car, thereby also gaining connecting-rod and crankshaft bearing area, and his consumption of cylinder oil will then compare favorably with that of the smaller motor pulling the smaller weight. The whole motor economy here involved can of course not be expressed in a few words, but it is quite well established that oil economy is not the forte of the ultra-light motor, and a shade of conservatism is in the matter of this item a source of operating economy. The use of eight-cylinder or twelve-cylinder motors of relatively short stroke and comparatively small specific pressures for a given power may also be worth investigating with a view to fuel, oil and tire economy. Neither is the Knight motor out of question.

Paring Down Over-All Dimensions

Comparisons must of course always have reference to cars of substantially the same size; giving the same degree of comfort for the same maximum number of occupants, the same degree of style. Economy gained by stinting any of these factors and in reality producing a medium-sized car which will serve the same purposes as are served by a large car, only not quite so generously, does not count in these reflections, though it may count for making sales and demonstrations. But if a general reduction of carriage dimensions is actually so managed that the comfort and style features remain unimpaired while the weight is reduced approximately in proportion to the dimensions, and tire economy is correspondingly increased, so as to equal that of the radically light construction, the means that may be adopted to that effect are properly to be seriously considered, as against the option of shouldering the problems of radical light-weight construction. All are not infatuated with large over-all dimensions, and it is proper to cater to variations in taste and to throw economical inducements into the bargain when possible. For example, if the backs of seats can be made thinner by new methods while the seating remains equally luxurious in all respects and ample, and by this means, in conjunction with a short type of motor, the whole frame length may be shortened 8 in., with the load better centered and suspended, the general reduction in weight due to the shortening is entitled to be considered on equal terms with a weight reduction accomplished without reducing the carriage dimensions. Some possibilities of this nature were exhibited at the recent show in New York, and while only time can fully demonstrate their worth they confirm the belief that studies in weight reduction, from a conservative standpoint, can be commenced in the carriage work with smaller risk and greater reward than in the chassis and running-gear—the motor remaining always a separate consideration. The advantage of the V-type for keeping the total weight down, where the luxury of more than four cylinders is wanted, may for cheaper cars even lead back to the four-cylinder upright placed crosswise which never was discarded for final reasons. With piston displacements constantly decreasing and thoroughly automatic production, even the use of two small four-cylinder motors crosswise may not be out of question for load-carrying vehicles, serving for fuel economy if one of them is always held in reserve for hard pulls. These remoter chances give a certain breadth to the question of means for effecting operating economy coupled with responsiveness.

Many Roads to Final Results

The order in which improvements are undertaken is after all the main issue in which there can be any divergence of opinion, since all must aim for final perfection and the case where one concern by one year's work accomplishes everything that can be done for such a comprehensive set of purposes as here in question, has never yet been better than imaginary.

Competing for Tire Economy

Reverting to the main line of thought, which deals solely with existing types of cars, the question now comes up: Having a car in which weights are somewhat but not radically reduced and in which the motor, the carbureter, the bearing areas and the lubricating system have been studied energetically with a view single to equalling the responsiveness and the fuel and oil economy of a still lighter car of comparable size, what can be done to equal or surpass this new competitor in tire economy?

It may be assumed that the ultra-light car itself is built with considerable thought in this direction, though it mainly relies on light weight. It probably has wire wheels, a rather low unsprung weight, a long wheelbase, a fairly well-centered load (without which the long wheelbase is useless for tire economy), springs of up-to-date material and design, with dampers attached.

To get full benefit of light weight it must however be equipped with tires whose fabric is so flexible as to absorb inequalities and thereby reduce the bouncing which the relatively light weight accentuates, and which cannot ordinarily be avoided economically by lower inflation. There is a choice between larger tires (which give increased flexibility) and cord tires (which also admit of lower inflation) for the radically light car, and in either case the question of the tire economy actually accomplished is one yet to be decided by tests. It is also to be viewed in connection with the question of comfort and of liability to tire injury. Just at what point on the scale of vehicle weights tire economy can be made to come unalloyed with drawbacks is not very well known, but on the whole and at equal speeds minimum weights make for economy and maximum actual weights make for comfort. The same degree of more than average ability which can give light-weight cars a comfortable tire action can probably give cars weighing 20 per cent more an economical tire action. Such an ability can aim to surpass all in tire economy with as good a chance of succeeding as the radical light-weight constructor has for surpassing standard construction in lightness without slipping into drawbacks of the kind that appear later or sporadically in a year's output.

Means Not Yet Exploited

Brakes and spring suspension afford a field in which to dig, probably the most promising one. Chains show a clear superiority in tire economy over shaft drive, partly owing to the smaller unsprung weight going with chain drive, but they have practically been ruled out for lack of a really good chain casing and for cluttering the space between wheel and carriage body. Other features have been ousted once, however, and have returned successfully under new conditions, and chains may again become standard for large cars of one price class or another; for example in connection with worm drive to the countershaft and remodeled brakes and springs. The worm would permit dispensing with a gear reduction between the sprockets, and parallel chains would make a chain casing simpler and sightlier, adjustments more satisfactory (as the two sprockets would wear alike). For the present, however, other changes are more in line with the trends in manufacture.

Smooth Gear Changes

In gear ratios there is a fully acknowledged study subject bearing more directly on tire wear than usually suspected, the ideal being that a change of gear shall cause no change in vehicle speed and therefore no sudden changes in wheelrim pull. THE AUTOMOBILE of Sept. 3, 1914, pages 450-452, and Oct. 1, 1914, pages 630-632, had articles on this subject adapted from the German originals by F. Achilles, and other material is available in French, German and English.

Brakes Worst Present Offenders

Brakes retard more rapidly and suddenly than carbureters, gear-changes or clutches can accelerate and must therefore in practice cause more strains and wear of tires than any which may be due to unsuitable gearing. Unlike clutches which have been developed and become gentle, brakes are still harsh when used harshly. In their improvement alone there may be more tire economy than in a 20 per cent weight reduction. Eventually, it would seem, rubber tires should not bear the brunt of any emergency brake service, as they now do. Drags are an alternative so far too rashly rejected. In spring suspensions, which temper the direct knocks and glancing blows that it is the business of tires to receive from all directions, it must of course be the object to establish as wide a range of suitable spring action as variations in speed, load and roads necessitate, and a glance around among the many efforts now being made for the bettering of spring action leaves it beyond serious doubt that the best and final spring suspension system is still at large. When recognized and developed, it may be enlisted in the competition for effecting operating and upkeep economy through special construction. Meanwhile, in the gradual improvement which is going on, there must be room for special efforts to surpass the average results, not only in the vehicle springs but in the cushioning of stresses throughout the car.

Extreme Light-Weight Always a Specialty

The means indicated—comprising better brakes, most suitable gear ratios, improved spring suspension and perhaps a modified chain drive for certain classes of vehicles—should suffice for relieving the search for upkeep economy of strain and excess in any one direction, while having the advantage of being widely applicable to all kinds of vehicles, in contrast to extreme light-weight construction which must be designed afresh for each model.

Means for Reducing the Glare of Lamps

WHEN regulations are contemplated by which the glare of automobile headlights may be reduced, one of the principal considerations is to avoid working a hardship upon the hundreds of thousands of motorists who are already the possessors of a complete lighting equipment. The measures recommended are therefore made as consistent with such normal equipments as possible and may consist only in prescribing that the headlights shall be mounted at such an angle and height that the center of the light cone is not above waist height at a certain distance, say 100 ft., in front of the car.

The subject can also be approached more radically and with a view to regulating the kind of lamps to be placed in the market in the future. Then it becomes important to know what is the cause of glare. A French lamp designer has answered this question in one word: Contrast. He maintains that a spot of strong light causes glare by contrasting so strongly with everything around it that the human eye cannot accommodate itself to both effects at the same time, and that the same amount of light extended to a line illuminates equally well, when correctly managed, while not troubling the optical nerves. He has designed a headlight board, as long as the car is broad, in which are set a dozen incandescent lamps, each with its reflector, and he mounts this board in a pair of pivoted arms by means of which it can be placed in three positions of different height above the ground. As the illumination received by the roadway is greatly increased if the light rays strike it at a large angle, he thus claims to accomplish at the same time a stronger illumination—with shortened shadows—and the elimination of all objectionable glare.

One Coat of Paint Better than Four

EXPERIMENTS conducted for the Royal Society of Art in England have shown that each fresh coat of pain put on top of another on an iron plate increases the amoun of rust which forms on the plate. Four plates painted wit one, two, three and four coats were exposed to steam for on day, the paint was dissolved off and the results mentione were observed. The explanation given is that each subsequent coat tends to dissolve a part of the previous one an renders it more porous. Air and moisture penetrate to th iron by way of the pores.

Watch-Like Accessories

RIVALING the watch in delicacy and accuracy of manufacture some of the accessories which are now placed on cars as standard equipment are monuments of painstaking care. The improvements which have been made this year in speedometers, horns and other equipment are as important as the improvements in the design of the car itself. The close limits of workmanship accompanied by lowering of prices due to the solution of problems of production have rendered accessories as a whole better although lower in price than ever before.

We have not come to the end of the movement toward better accessories, however, and the tendency toward better materials and finer workmanship must be carried on in answer to the demands of the general public for the best there is to be had in equipment. It is true to such a large extent that the equipment sells the car, that the manufacturer of automobiles cannot afford to neglect the quality of what he puts on his car. The consequence of this is that the manufacturer of an accessory, if he wishes to bid for a contract for standard equipment on a stock car, must show something beyond mere low price before his product will be considered.

much too little scope, so in saying that
bile body of 1916 is much better on the average than it has ever been before, it is not to be assumed that finality has by any means been reached.

There are still only a few bodies which are perfectly comfortable. There are equally few that are quite as light and strong as they might be, and it is easy to criticize the appearance of many others. Interest in body designing and in body engineering is quite recent; it is only within a few years that the subject has received the attention it deserves, so it is reasonable to expect extended development during the next several years. The progress made since January, 1914, is remarkable, and if the pace is maintained another couple of years may easily see something like a final type evolved.

The Chicago Show

IT seems likely that this year the Chicago show will differ less than usual from the show just concluded at New York, so far as concerns the exhibits. In 1915 the manufacturers announced their new models early, and we have had nothing to correspond to the rush of eights which occurred in January of last year.

At the 1915 Chicago show were a good many new cars which could not be got ready in time for New York and were sprung as surprises, though anticipated by the inner circle. This year there are scarcely any forethoughts of this nature.

berg, the axles Sailsbury, the transmission Covert, the steering gear Ross, the ignition system Bosch, and the tires Firestone pneumatic, 33 by 4½. The radiator is of the cast tank type, vertical tubes. The springs are semi-elliptic, 36 by 2¼ in front and 56 by 3 in. rear.

The truck was designed by an English engineer, W. L. Bodman. Those interested in this new company are: J. A. Moritz and L. F. Mullin, members of the firm of Moritz-Mullin Co., distributor of the Signal trucks, and J. E. Hannon.

Equipment for Fords

The Detroit Auto Products Co. shows its roadster de luxe body and equipment for the Ford for the first time. This complete equipment consists, in addition to the special body, of a one man top with boot and side curtains, ventilating windshield, radiator, hood, crown fenders, lamp bracket extensions, tire holder brackets, splash plates, dust shields, foot accelerator, starting crank and running board hangers. A Ford roadster thus equipped weighs 1540 lb. The standard color is Brewster green. The body is 45 in. wide at the seat, back of dash to front of cushion, 30 in.; cushion, 18 in. deep, 10 in. high at front and 7 in. high at back. The price of this equipment is $197.50 f.o.b. Detroit. A closed top to convert the roadster into a coupé will also be brought out by the company.

Fritchle Preparing Gas-Electric Model

DENVER, COL., Jan. 15—The Fritchle Automobile & Battery Co., this city, is bringing out a gas-electric car to be operated the same as its electric model with one electric unit and a four-cylinder air-cooled motor. There will be no change gear mechanism or a clutch, the electric battery power being consumed only on low speeds and heavy pulls through mud and up hill, the engine cutting in automatically. The battery is charged automatically at speeds between 12 and 20 m.p.h. Higher speeds are obtained by using both the engine and battery at the same time.

General Rise in Tire Prices

NEW YORK CITY, Jan. 19—Republic tire prices went up 5 to 10 per cent today, thus supplementing the general rise which was started Monday when the United States Tire Co. advanced its prices 10 per cent on all grades of its tires. Yesterday, Goodrich, Goodyear, and Firestone announced increases. Goodrich tires are now selling 10 per cent higher on the usual sizes of both cord and fabric types, no changes as yet having been made on the unusual or less popular sizes. Goodyear also increased its prices 10 per cent on both its cord and fabric types; and Firestone announces a 10 per cent increase. Goodrich has raised its prices on the 28 by 3-in. tires from $8.50 to $9.35; on the 34 by 4 from $19.40 to $21.34; and on the 36 by 4, from $20.50 to $22.55. The Goodyear 32 by 3½-in. size is now selling at $14.70 as against the former price of $13.35; the 34 by 4 is now $21.35, compared with $19.40; and the 36 by 4½ quotes at $30.10, compared with $27.35.

A number of the tire companies have not as yet announced any changes but expect to. The Hardman company expects to go up 10 to 20 per cent in the near future and is at present taking few orders at the prevailing prices. The Ajax company expects to raise its prices the last of the week, and Diamond tire prices, it is stated, are slated to go up.

These rises now include ten since Jan. 6, when Kelly-Springfield started the increase with a 7½ to 26 per cent jump. As announced in THE AUTOMOBILE last week, Empire list prices went up 15 per cent; Falls rose 10 per cent, and Globe and Pennsylvania went up approximately 25 and 20 per cent each.

Some of the new prices on United States Tire, Goodyear and Goodrich are as follows:

Goodrich Tires

Size	Old	New
28 by 3	$8.50	$9.35
34 by 4	19.40	21.34
36 by 4	20.50	22.55

U. S. Tires

Size	Old	New
32 by 3½	$13.35	$14.70
34 by 4	19.40	21.35
36 by 4½	27.35	30.10

Coghlan a Klaxon Director

NEWARK, N. J., Jan. 18—At the annual stockholders' meeting, W. P. Coghlan was elected a director; and at the directors' meeting was made secretary of this company. He will continue as general sales manager.

Blood Bros. Elects New Directors

GRAND RAPIDS, MICH., Jan. 14—At the annual election of the Blood Brothers Machine Co., Allegan, Mich., manufacturer of the Cornelian car, the following directors were elected: F. I. Chichester, L. H. Mattingly of Kalamazoo, Judge O. S. Cross, C. C. Blood and Mr. Potter.

Couple-Gear Directorate Chosen

GRAND RAPIDS, MICH., Jan. 14—The folowing directors have been chosen for the Couple-Gear Co., Grand Rapids, Mich.: George Hummer, W. C. Hopson, A. J. Brown, F. E. Brown, Alexander Dodds, Clayton Church, W. B. Church, M. S. Hopkins, A. B. Knowlson. According to reports of officers the company has just completed a successful year. Most of its product is disposed of in Boston and New York.

Four Buildings for Chicago Show

Nearly All N. Y. Exhibitors Have Space with Several Others Added

CHICAGO, ILL., Jan. 19—Chicago will be host to the 1916 models, the newest accessories and legions of motor car connoisseurs and dealers Saturday and the week following when the sixteenth annual motor show, held under the auspices of the National Automobile Chamber of Commerce and the management of Samuel A. Miles, will be staged in this city. So large is the impending display of cars that four buildings will be required to house them—the Coliseum, the Coliseum Annex, the First Regiment Armory and the Greer Building.

As at previous shows, the cars will be shown on the main floors of the Coliseum, Coliseum Annex and the First Regiment Armory, with the overflow in the Greer Building, while the accessories will be displayed in the basement and the gallery of the Coliseum and the balcony of the armory and Coliseum annex.

New York Exhibitors Represented

With only one or two exceptions, all the car makers exhibiting at New York will play a return engagement here. The most notable absentee will be the Fergus, the stripped chassis from the land of the Shamrock which attracted so much attention at New York because of ease of maintenance and simplicity of lubrication. Several companies, however, that did not show at New York will have models here, including the Farmac, Elgin, Monitor, Elcar, Halliday, Champion, Crow-Elkhart and Chicago Electric.

More than 200 manufacturers of parts and accessories have reserved space and this insures a display of fitments equal to that of past exhibitions.

Japanese Decorations

When the doors of the four exhibition buildings open at 2 o'clock Saturday afternoon, four gardens of old Japan will be revealed as decorations symbolic of the Mikado's realm have been selected for the 1916 show and the decorative scheme will be carried out in each of the buildings. The work of transforming the bare structures into places of beauty was started last week and the decorators will be through by Thursday when the cars, which now are sidetracked in local freight yards, will be put in place.

Nothing, from the artistic viewpoint, has approached in beauty the decorative scheme which prevails in each building. Four parks of quaint Tokio have been reproduced by artist Tietzel at a cost of approximately $50,000. Monumental gates, towers and pagodas have been erected. The walls are screened with the foliage of cherry trees. Ninety thousand square feet of canvas have been used to obtain a blue sky effect. In fact, the Chicago show will have a Nipponese atmosphere that might seem to be more suited for the display of jinrickishas than the exhibition of motor cars.

As Chicago is the center of a great distributing territory, the local show will be the mecca of dealers from all points of the compass for a radius of 200 miles and luncheons and dinners, at which the men who deal directly with the ultimate consumer will be guests, will feature the week. Wednesday will be Society day and also the occasion of the annual meeting of the National Automobile Chamber of Commerce.

Dealers from Texas

A feature of the week will be the visit of a delegation of 150 Texas dealers who are scheduled to arrive Monday morning on special trains from Fort Worth and El Paso. The Overland representatives in the Northwest will give the Chicago show the double O on opening day before going to Toledo to inspect the Willys-Overland plant.

An appeal will be made to the patriotism of the motorists of the Middle West during the week of the show by the Chicago Automobile Club, which will maintain a recruiting office in the Coliseum where owners of cars may enlist in the motor car reserve corps and thereby take an active part in the preparedness campaign for national defense.

Jeffery Has New Sales Force

Kenosha, Wis., Jan. 17—E. S. Jordan, who for nearly eight years has been in entire charge of sales for the Thomas B. Jeffery Co., having resigned, the sale of Jeffery pleasure cars hereafter will be in charge of E. G. Howard, as sales manager, and W. B. Riley as assistant sales manager; the truck sales department will be in charge of H. C. Hart and the foreign sales department will be in charge of J. A. Rose. All of these men have been connected with the Jeffery company for a number of years.

Premier Board Elected

Joliet, Ill., Jan. 18—Stockholders of the new Premier Automobile Co., Indianapolis, Ind., mostly composed of capitalists of Joliet, held their organization meeting this week, directors being chosen as follows: H. L. Thompson, C. F. Jensen, E. W. Steinhart, J. C. Flowers, Theodore Gerlach, F. W. Woodruff, and G. E. Woodruff. The directors then elected these officers: President, J. C. Flowers; vice-president, E. W. Steinhart; secretary, C. F. Jensen; treasurer, H. L. Thompson.

Many Trucks in Detroit Show

Fewer Electrics and a Good Range of Gasoline Cars

Detroit, Mich., Jan. 15—Although there were twenty less cars on a floor of the three buildings used this year at the fifteenth annual automobile show promoted by the Detroit Automobile Dealers' Association, it was held by the first nighters and by exhibitors to be the best one as yet seen in the automobile metropolis of the world.

It is a more interesting show than its predecessors, as practically all the novelties in construction that were shown in New York are also to be found here. It is, as an Easterner said, a miniature New York show with an excellent commercial vehicle section in addition. Perhaps one most regretted absentee is the new Marmon car, but its local distributor is showing the car in the lobby of the Hotel Statler, not having been able to secure the desired space.

No Newcomers

A feature this year is practically the entire absence of entirely new cars. In the passenger car line there is no newcomer. There are, however, quite a few cars which had never previously been seen in this city. In the commercial car line there is a new truck, the Lincoln. Several other trucks unknown to Detroit heretofore, but well known in the country otherwise, are shown. Among the accessories and parts exhibitors there are several who either are new in the business and thus show their wares for the first time, as for instance the Detroit Auto Products Co., Dr. Schorr's suspension, and the Meyer Motor Co.

Cars and chassis on the floor totaled 183 as compared with 203 last year. There are 115 gasoline passenger cars and sixteen chassis; thirty gasoline commercial vehicles and twelve such chassis, and ten electric passenger cars. It is the latter class which shows shrinkage in number, although not in quality, as last year there were twenty-five electrics at the show.

New Lincoln Truck

The Lincoln Motor Truck Co. has its new ¾-ton truck on display. With express body and the usual accessories, it sells at $985. The chassis only is listed at $925. Electric starting and lighting system will be furnished at an addition of $100. The wheelbase of the truck is 122 in. The maximum body length is 10 ft. The motor is a four-cylinder Beaver, 3¾ by 5 in.; the carbureter a Stromberg, the axles Sailsbury, the transmission Covert, the steering gear Ross, the ignition system Bosch, and the tires Firestone pneumatic, 33 by 4½. The radiator is of the cast tank type, vertical tubes. The springs are semi-elliptic, 36 by 2¼ in front and 56 by 3 in. rear.

The truck was designed by an English engineer, W. L. Bodman. Those interested in this new company are: J. A. Moritz and L. F. Mullin, members of the firm of Moritz-Mullin Co., distributor of the Signal trucks, and J. E. Hannon.

Equipment for Fords

The Detroit Auto Products Co. shows its roadster de luxe body and equipment for the Ford for the first time. This complete equipment consists, in addition to the special body, of a one man top with boot and side curtains, ventilating windshield, radiator, hood, crown fenders, lamp bracket extensions, tire holder brackets, splash plates, dust shields, foot accelerator, starting crank and running board hangers. A Ford roadster thus equipped weighs 1540 lb. The standard color is Brewster green. The body is 45 in. wide at the seat, back of dash to front of cushion, 30 in.; cushion, 18 in. deep, 10 in. high at front and 7 in. high at back. The price of this equipment is $197.50 f.o.b. Detroit. A closed top to convert the roadster into a coupé will also be brought out by the company.

Beyerline to Organize New Mfg. Co.

Detroit, Mich., Jan. 17—J. G. Beyerline and W. L. Daly, who were respectively president and general manager, and general sales and advertising manager of the King Motor Car Co. are among those principally interested in a new automobile company which will make a six-cylinder car to sell at $900. Both the manufacturing and selling organizations of the new concern are now being perfected and a complete detailed announcement will be made shortly.

Motor Body Co. Building New Plant

Detroit, Mich., Jan. 17—A new plant is now in course of construction for the Motor Truck Body Co. at Central Avenue and the M. C. R. R. It will be a one-story structure, 64 by 245 ft. There is in addition 2½ acres of ground which may be utilized for further expansion. The company manufactures special truck bodies. E. G. Proctor is president and E. G. Thurber is secretary and treasurer of the company.

Detroit, Mich., Jan. 17—The Liberty Motor Car Co. capitalized at $400,000 has been formed here. The incorporators are George B. Allen, J. B. Clark and F. W. Henning.

41,000 See Milwaukee Show

Business Transactions Largest Ever Held—Wis. Dealers Hold Banquet for 600

MILWAUKEE, WIS., Jan. 17—Approximately 41,000 people passed through the gates of the eighth annual show of the Milwaukee Automobile Dealers, Inc., held in the Auditorium from Jan. 7 to 13, inclusive.

Exhibitors declare that more actual business was transacted at this show than at any previous Milwaukee exposition. While the volume of business is less, due to the general drop in average price of cars for 1916, more cars were sold and the purchases of detachable winter tops have never been equaled. The number of Wisconsin dealers who actually registered at the show is 15 per cent larger than for 1915, indicating that wholesale business increased in a similar proportion.

From a financial standpoint the 1916 show was the best of the eight expositions which Milwaukee dealers have put on.

The weather ran riot during the seven days of the show. Friday, opening night, was accompanied by mist and a temperature of 23 deg. above zero. On the following Wednesday morning the thermometer showed 20 deg. below zero, the coldest Milwaukee has experienced in ten years. In the interim there was rain, snow, fog and mist. No more unfavorable weather has ever been known during a Milwaukee show. On only a few days was it possible for exhibitors to make outdoor demonstrations with the least degree of comfort at all.

Prosperity talk was rife, both among the banqueters and the speakers. Wisconsin registered 79,791 cars in 1915, a gain of nearly 27,000 cars for the year, and predictions were freely made that 30,000 cars will be absorbed by the Badger State in 1916, making a total of nearly 110,000. It was pointed out that motor car business varies with the size of the annual crop, and bumper crops in 1915 mean big sales in 1916. Approximately 60 per cent are purchased in the rural districts and 40 per cent in cities.

Practically every State agent or agency tendered dinners to its sub-dealers during show week.

250 Cars in Baltimore Show

BALTIMORE, MD., Jan. 18—Baltimore's tenth annual automobile show opened at the Fifth Regiment Armory to-night. It is being held under the auspices of the Automobile Club of Maryland and the Baltimore Automobile Dealers' Association. It will close on Saturday night.

The show is by far the greatest local exhibition of pleasure and commercial cars ever held in Baltimore, there being sixty-eight exhibitors showing 250 machines. The estimated value of the exhibits and decorations is $1,500,000. Fifty-one different makes of pleasure cars and twenty-eight different makes of trucks are included in the exhibit.

Schrader, Tire Valve Inventor, Dies at Sea

NEW YORK CITY, Jan. 14—G. H. F. Schrader, formerly president of A. Schrader's Sons, Brooklyn, N. Y., and who invented the Schrader valve for tires, died on Nov. 15 last on board a fishing boat en route from Iceland to Norway. Mr. Schrader left this country about six years ago for England and after spending two years in Falmouth he suddenly went to Iceland. About three months ago he became ill and decided to return to the United States. He could get no passport, however, in Iceland, and so decided to take passage aboard a trawler for Norway, where he could establish his identity.

Mr. Schrader was a few months less than sixty years old. He was born in Hoboken. He was a bachelor, and, so far as is known, had only one relative, a sister now supposed to be in Germany.

Form Tractor Club in Kansas City

KANSAS CITY, MO., Jan. 17—The Tractor Club of Kansas City has been organized by the local representatives of about fifteen tractor manufacturers. A. J. Pray, of the Universal Tractor Company, is president, with W. F. Roth, Emerson-Brantingham Company, vice-president, and Guy H. Hall, Hall Bros. & Reeves, secretary and treasurer. The directors are E. J. Anderson, Avery Company; A. F. Norton, J. I. Case Threshing Machine Company; J. P. Smith, Rock Island Implement Company; G. C. Weyland, J. I. Case Plow Works, and C. E. Haynie, International Harvester Company.

Lehr Co. to Build Saginaw Eight

SAGINAW, MICH., Jan. 14—The Lehr Motor Co., this city, has been formed under Maine laws with a capital of $500,000 to build the Saginaw Eight at $1,050. The designer and general manager is Harry D. Mackey; president, William M. Guilder; vice-president, F. F. Myer, and secretary and treasurer, K. M. Schwahn.

Jackman Is Westinghouse Representative

CHICAGO, ILL., Jan. 14—A. E. Jackman has been appointed as the Western representative of the automobile equipment department of the Westinghouse Electric & Mfg. Co., this city.

Automobile Shipments Delayed

Only 59,000 Freight Cars Available — Several Railroads Building New Cars

DETROIT, MICH., Jan. 14—At a meeting of the traffic committee of the National Automobile Chamber of Commerce, Inc., together with traffic managers of various railroads, the traffic managers decided to ask that the automobile industry make it a rule to unload all incoming freight cars the day of their arrival. This step was taken in order to guard against the shortage of freight cars which is pending at the present time because the railroad companies have not kept pace with the expansion of the automobile industry by adding to their equipment of automobile freight cars.

At present there are only 59,000 automobile freight cars available. The New York Central is building 9000 additional, and the Pennsylvania is building 1000 extra. This puts the total at 69,000, which is not adequate to meet the demands. Up to the present time Detroit, Toledo, Flint, Lansing, Cleveland, and other manufacturing cities have not been severely handicapped in a shortage of cars. Shipments have been held up a day or so but the prospects are that when production is at its height in February there will be a very great shortage, and it is to guard against this shortage that the decision above referred to was arrived at.

N. A. C. C. Probes Situation

The N. A. C. C. through its traffic committee is following every automobile freight car from the time it leaves the factory until unloaded by the dealer and returned to the factory. This committee is working to guard against delays by the dealer in holding a car on the railroad siding for several days before unloading.

During 1915 approximately 200,000 carloads of automobiles were shipped by members of the N. A. C. C. or about 60,000 more than in 1914. During the last three months of 1915 members of the N. A. C. C. shipped 47,600 carloads or 24,000 more than during the corresponding period of 1914.

The following officers were elected at the meeting for the year 1916 by the Detroit traffic committee. C. W. Eggers, Willys-Overland Co., chairman; E. N. Hodges, Hupp Motor Car Co., vice-chairman; W. L. Schultz, Hudson Motor Car Co., secretary-treasurer.

Those in attendance in addition to the above were: M. S. Graham, Reo Motor Car Co.; C. J. Shaar, Packard Motor Car Co.; H. J. St. Aubin, Federal Motor

Truck Co.; George A. Main, Maxwell Motor Co.; Hugh Higginbottom, Dodge Bros.; H. R. Moule, Chalmers Motor Co.; H. E. Johnson, Studebaker Corp.; T. M. Smith, National Motor Vehicle Co.; W. L. Pierce, King Motor Car Co.; E. B. Rodgers, Olds Motor Works. There were also at the meeting, J. S. Marvin, traffic manager of the National Automobile Chamber of Commerce; William E. Metzger, chairman of the traffic committee of the N. A. C. C.; Arthur T. Waterfall, traffic commissioner of the Detroit Board of Commerce.

Springfield Body Offers $750,000 Preferred Stock

New York City, Jan. 19—For the purpose of putting its Springfield plant on a large production basis and for the construction of a plant in Detroit, which will supplement that in Springfield, the Springfield Body Corp. has offered, through Renskorf, Lyon & Co., New York City, $750,000 8 per cent cumulative and participating preferred stock at par. The stock is redeemable at 200 at the option of the company after Jan. 1, 1917. This is the first offering of an authorized issue of $1,000,000 preferred stock.

All of the common stock of the company, amounting to $1,500,000, was issued to holders of the old stock in payment for the company, which was formed when it took over the old Springfield Body Co. last year.

Waukesha Bridge to Build Tractors

Waukesha, Wis., Jan. 17—The Federal Bridge Co., Waukesha, Wis., formerly Modern Steel Structural Co., has booked another large contract to manufacture gasoline tractors for outside concerns, and during the present year will produce approximately 2500 farm machines. It was announced some time ago that the Waukesha plant would build tractors, but it was explained that this line was being undertaken only as a contractor. A short time ago the Nillson Farm Machinery Co., Minneapolis, Minn., contracted for the manufacture of 300 tractors, and now the Paramount Farm Tractor Co. has contracted for 1200 machines.

Signal Truck Increases Capital

Detroit, Mich., Jan. 15—The Signal Motor Truck Co., is completing arrangements to increase its capital stock from $85,000 to $450,000. Of this amount $300,000 will be common stock and $150,000 7 per cent accumulative preferred. It will be provided for protection of preferred stockholders that no dividends will be paid on the common which will reduce the net current assets to a total of 125 per cent less than the amount of preferred outstanding. Furthermore, it will be provided that for each dividend on common stock cash of an equal amount is to be appropriated to a reserve for the retirement of the preferred stock. The common stock will be placed in a five-year voting trust.

The company will be known as the Signal Motor Truck Co. of Maine, under laws of which State it will be incorporated and it will take over the assets and business of the Signal Motor Truck Co. of Michigan. Application will be made for the listing of the stock on the Detroit Stock Exchange.

Stephens Car is New Product

Freeport, Ill., Jan. 17—The manufacture of automobiles by the Moline Plow Co. will commence March 1, in the Henney Buggy plant. The car will be known as the "Stephens." The test chassis which has been constructed at Detroit as a model, reached Freeport this week, being driven overland by M. A. Steele, general manager; J. T. Trumble, chief engineer, and J. C. Holden, head draftsman. The car has six cylinders.

Rubber Club to Expedite Tire Shipments

New York City, Jan. 19—The Rubber Club of America, which is officially handling the crude rubber situation in America, during the period of the rubber embargo by Great Britain, has been working to make it easier for American exporters to get quicker service on tires for motor cars or trucks which have been shipped to neutral countries, and which must be shipped without tires under the restrictions of the embargo. The Rubber Club is circulating to the manufacturers a special form which when filled out will be forwarded by the Rubber Club to the war trade department in London. These forms are for licenses for tires for the vehicles shipped to neutral countries. At present sometimes months pass before tires can be secured through London for such vehicles, and the purpose of the present form is that this time can be greatly reduced. The forms are really a hurry-up certification from the Rubber Club to the war trade department that the orders are reliable and should be filled with the utmost dispatch.

Dorris Reduces I A W 2-Tonner Price to $1,190

St. Louis, Mo., Jan. 15—The Dorris Motor Car Co., this city, has reduced the price of its I A W 2-ton worm drive truck chassis to $1,990, f.o.b. St. Louis. There is now to be an extra charge for the governor and driver's seat, if wanted. The former price on this truck chassis was $2,500.

Truck Trade Flourishing

General Motors Dealers' Convention Shows Orders Sufficient for All Year

Pontiac, Mich., Jan. 18—With the new year less than a month old, orders in the hands of many dealers and distributors of trucks are ten times, and more, better than at this time last year. In some instances there have been 25 per cent more sales. The situation is without precedent, and, according to old truck dealers, it means that truck manufacturers will have to provide themselves with ample means as far as materials are concerned, if they want to cope with the demand, or rather with the orders they will receive right along from their dealers.

These were the chief points brought out at a three-days' convention of branch managers and salesmen of the General Motors Truck Co., held here this week. They came from all sections of the United States and some from the Dominion, and the feature of the gathering was the unanimous opinion of those present, that the truck business of 1916 will far surpass in the number of commercial vehicles sold, any figure anticipated or predicted at the present time.

The conditions are good everywhere for the truck business. The education of the prospective users of commercial cars has made such strides that to-day there is hardly any successful business man who does not intend to take on the motor-driven vehicle, or add some to those he already has.

From what some dealers say, orders for trucks now on the books of truck manufacturers are sufficient to keep them well busy practically all year. And many will have day and night shifts a greater part of the year.

New Tractor Ready Feb. 21

Big Rapids, Mich., Jan. 1—The Four-Drive Tractor Co., this city, has been formed to build a tractor after the invention of John Fitch. A plant 45 by 200 ft. will be built on the company's property near the Père Marquette Railroad. The building is expected to be finished April 15.

The Four-Drive Tractor Co. expects to have a tractor ready for the Grand Rapids automobile show which begins Feb. 21. President Finch has been out scouting for material and already a quantity of machinery has arrived at the plant of the Binney Machine Co. in preparation for manufacturing operations in that city.

Gasoline Prices Soar to New Marks

Quotations in Six Cities Reach 22-Cent Mark—Panama Slide Important Factor As It Cut Off Cheap Transportation from Cal.

NEW YORK CITY, Jan. 18—The further increase of gasoline prices last week in this and other large cities throughout the country has caused many of the automobile owners to wonder just when the upward movement is going to stop. There seems to be no set price as the quotations given do not seem to coincide with the location of the city with reference to that of the refineries. For instance, Chicago is less favored in respect to manufacturing facilities than New York, yet the prices in the latter city are at the present time 4 cents higher than in Chicago. Both cities are well served by refineries and have excellent connections with the oil fields. Looking over the appended table of prices, it will be seen that there are just five cities in the United States that are paying prices as high as those now quoted in New York, and among them are several remote from the base of supplies, one being Tucson, Ariz. Detroit prices at the present time are quoting under 20 cents.

Transportation Rates Higher

It is stated, among many of the reasons for the recent increase of prices, the Panama slide was an important factor, as it cut cheap transportation from California, and the reopening would have afforded some relief. The oil now coming from California to the East must pay trans-continental gasoline railroad rates. The oil produced in Eastern Mexico was practically all going to England in tank steamers requisitioned by the British Government.

It is stated that a tank car of gasoline which cost $500 a few months ago now costs $1,500, same delivery, Oklahoma or elsewhere. A tank car of oil that could have been had at 1¼ to 1½ cents a gallon now costs 3 to 3¼ cents, and lubricating oils have advanced 40 to 100 per cent.

Exported Gasoline Higher

Last week the Standard Oil Co. of New York advanced the export price of gasoline stove grade 1 cent a gallon and all other grades 2 cents a gallon. Retailers in New York City have raised the price in some cases to 28 cents a gallon. One wholesaler gave the opinion that 3 cents a gallon was a fair profit for retailers, but the retailers state that no profit under 5 cents a gallon is possible to make fair earnings, as allowance for overhead charges and evaporation and waste must be accounted for.

The call for substitutes or new processes to cheapen production has been manifest during the last few months. The latest process is that of H. T. Yaryan of Toledo, Ohio, who states that by his process gasoline can be produced for 10 cents a gallon by means of an invention of his which will get 90 per cent of gasoline out of the crude oil, instead of 20 per cent, which the present oil companies are stated to be getting. According to the inventor, by his process he can make all of the by-products of crude oil, including kerosene, paraffine, tar and greases, up into gasoline. When his process is finished, nothing but tar is left, the rest being gasoline.

The Atlantic Refining Co. in Philadelphia and Pittsburgh has raised the price of gasoline 1 cent to 21 and 22 cents, respectively.

Portland, Ore., prices were advanced last week 1 cent to 15 and 16½ cents, retail. Tacoma prices again advanced 1 cent to 16½ cents.

Investigation in New Jersey

The recent rise in gasoline prices in New Jersey has caused a resolution to be be passed in the House of the Legislature for a thorough inquiry of the conditions leading to the higher prices. The Judiciary committee of the House will conduct the investigation. It is conceded by many in that State that gasoline is no longer a luxury, but a necessity, because of the extensive use of the commodity for commercial purposes.

$1 Tax for Overcharge

A bill intended to reduce the price of gasoline was introduced yesterday by Representative Ben Johnson of Kentucky. It proposes that whenever the first vender sells a gallon of gasoline at a price as high as 15 cents, he shall pay a tax of $1 for each gallon, and an additional tax of $1 a gallon for each cent above that figure.

—

Farmers Oppose Gasoline Tax

FRESNO, CAL., Jan. 14—Automobile owners, dealers and farmers using tractors on their farms, representing the San Joaquin Valley, attended a mass meeting held in this city yesterday and protested vigorously against the emergency war taxes on gas engine, horsepower and gasoline to President Wilson and members of Congress.

Resolutions strongly objecting to the proposed taxes were passed and adopted. These resolutions are to be sent to Washington. In the resolutions the tax is declared to be unjust on the grounds that automobiles are necessary to progress and prosperity and that the progress of California is largely dependent on the use of automobiles and gas engines in pumping plants and farm machinery.

The following table gives a range of the current prices:

	Present Price	April 1	Increase
Atlanta, Ga.	21	12.5	8.5
Baltimore, Md.	21	11	10
Boston, Mass.	22	13	9
Buffalo, N. Y.......	18	12	6

Government Constructs Armored Car at Rock Island

ROCK ISLAND, ILL., Jan. 17—There is being finished at the government arsenal in Rock Island, an armored car for the United States war department, which is the first of the kind to be constructed in this country. Originally, the car was a Jeffery commercial truck. A 45-hp. engine has been substituted for the thirty, first installed, and when the car is ready for service a test will be made upon the arsenal drives. The entire machine, with the exception of the wheels, is protected with 2/10-in. armor, though armor plate will be substituted later. There are loop holes for the use of field glasses and two revolving turrets, on each of which is mounted a rapid-fire gun, each discharging 450 shots per minute, though this can be increased to 600 if necessary. The car will carry six men. Driving apparatus, which permits the car to go ahead or backward, is in position but is operated separately, thus requiring one man for each, the other four men to handle the rapid fire guns.

Work also has been started on a lighter and speedier armored automobile, which will be armed with one machine gun and carry a crew of two or three men.

Experiments have demonstrated that armor plate 2/10 in. thick will resist small-arms fire. This is as thick as the shields used on the machine guns in use in the European war.

The War Department also is planning a motor vehicle equipped with small rapid-fire guns, but limitation as to weight materially restricts the amount of armament that can be placed on such a vehicle. On account of the character of the roads here it will be impossible to use as heavy armored trucks in this country as in Europe, the limit of safe weight having been found here to be 8500 lb. England has purchased in this country supply trucks that weigh loaded between 12,000 and 13,000 lb. Trucks as heavy as this would wreck many of our country bridges.

To Compel Truck Fenders

CHICAGO, ILL., Jan. 18—Although the ordinance, stipulating that all motor trucks operating in this city shall be equipped with fenders, has been declared invalid, mandamus proceedings have been instituted against Chief of Police Healey to compel its enforcement by five makers of fenders. The bill of complaint states that of the fifty-nine persons killed by motor trucks in Chicago during the past 11 months, twenty-six were children whose lives would have been saved had the vehicles carried fenders.

Durant-Dort Capital Increased

FLINT, MICH., Jan. 15—The capital stock of the Durant-Dort Carriage Co. has been reduced from $2,000,000 to $1,000,000.

War Automobiles Sent Direct to Petrograd

GRAND HAVEN, MICH., Jan. 14—Transfer shipments of war automobiles and accessories have been handled by the local lake lines, the shipments being routed direct to Petrograd in the main. The Grand Trunk railroad is handling the major portion of the shipments.

British Tire Blockade Hits Dutch

PARIS, Dec. 30—Travelers from Holland report that England's tire blockade is so tight that only the minimum number of tires necessary for public service are allowed to pass into Dutch territory. Automobile owners are not allowed to have new tires until they have returned their old casings and tubes, even though they are unfit for any further service.

Notwithstanding the severity of the control and the heavy fines imposed, smugglers make repeated attempts to get rubber across the frontier into Germany. The market price of rubber in Holland is at present about $1.60 per pound. The penalty for those caught in the act of smuggling is $6.40 a pound; but as German agents are willing to pay $10 a pound for all rubber brought across the frontier, smuggling is a profitable, though dangerous, occupation.

Must Notify Insurance Co. Immediately

LANSING, MICH., Jan. 14—The Supreme Court of Michigan in a decision affecting the Oakland Motor Car Co., Pontiac, Mich., held that when a liability insurance company is notified about an accident three months after it occurred that this is not an immediate notification. In this particular case the Oakland company had a liability insurance policy with the American Fidelity Co., covering automobiles used by the Pontiac manufacturer for testing in Pontiac. One of the cars while on a testing run was the cause of a runaway, and a Mrs. Sarah Gregory was hurt. She brought action for recovery of damages, and was given a verdict for $1,500. The Oakland Motor Car Co. brought suit against the insurance company for this amount, but the American Fidelity Co. refused to settle, claiming that its agreement with the Oakland company specifies that it must be notified immediately about accidents, and in this instance the insurance company was notified three months after the accident occurred. In a lower court a decision was rendered in favor of the Oakland Motor Car Co., but now the supreme court reversed the decision without a new trial.

Synthetic Rubber in German Tires

BERLIN, GERMANY, Jan. 14—Automobile tires of artificial rubber are now being made in Germany. In his address to the Reichstag last week Chancellor von Bethmann Hollweg stated that German inventors had discovered a method of producing synthetic rubber. It was stated that at almost the same hour that the Chancellor's statement was made, a factory succeeded in working this rubber into tires which will wear for a year.

Hercules Plant Erection Started

CANTON, OHIO, Jan. 17—Ground has been broken for the erection of the plant of the Hercules Motor Mfg. Co., which will build a light delivery wagon. The plant will be 75 by 360 ft. and will be completed within sixty days.

Consolidated Car Co. Enlarges Plant

DETROIT, MICH., Jan. 17—The Consolidated Car Co. which makes the Abbott-Detroit cars concluded a deal whereby it has taken over the plant of Schweppe & Wilt at Meldrum and Lafayette Avenue, East. The latter company will move into a new plant on Mt. Elliott.

60,000 Cars at French Front

Repair Factories with Power Equipment Behind Lines Can Be Moved Rapidly

PARIS, FRANCE, Jan. 14—According to dispatches sent out from this city, there are at present about 60,000 automobiles, worth $60,000,000, in use on the fighting lines in France. The machines are having the hardest kind of use and yet but 25 per cent are under repair. Each army now possesses a large repair camp. It is a novel feature of army organization. Up to two months ago machines needing repairs had to be sent to garages in the nearest large city. To avoid loss of time, regular factories equipped with machinery for automobile construction have been built behind each army. They consist of about a dozen enormous wooden sheds covered with waterproof canvas.

Electricity generated on the spot operates all the lathes. Two hundred mechanics work night and day in two shifts. Spare parts of every description for every make of car, tires, lamps, headlights and every possible accessory are kept in large stock. Everything is so arranged that the whole camp, including the sheds, can be moved bodily to another part of the country within a week. Emergency workshops, composed of three automobile wagons, carrying all repair tools and an ample supply of spare parts, are kept in perpetual readiness, should the army suddenly advance.

Special Burd Ring for High Speed Motors

ROCKFORD, ILL., Jan. 14—A new Burd piston ring has been developed by the Burd High Compression Ring Co. which will be known to the trade as the "Burd high speed model." In appearance it is not dissimilar to the standard Burd ring, and to the layman there is little or no evidence of change from the former specifications. It is intended to meet the difficult requirements of aeroplane motors and high power car engines.

The aluminum alloy piston calls for greater clearances between the piston and cylinder walls, to provide for the greater expansion. The Burd high speed model piston ring is especially adapted to meet these unusual conditions.

Jones Now Johns-Manville Speedometer

NEW YORK CITY, Jan. 13—H. W. Johns-Manville Co., announces that the name "Jones" has been discontinued in connection with its speedometer, which is now known as the Johns-Manville speedometer.

Five Year Trust for Entz Patents

Six Members Represent General Electric Co. and Owen Magnetic Co.

New York City, Jan. 15—A voting trust has been constituted in connection with the Entz Motor Patent Corp., controlling the Entz electric transmission patents, large interests in which were recently purchased by the General Electric Co., from R. M. Owen & Co., which previously controlled them exclusively. The voting trust will exist for five years and the power of voting the stock of the corporation rests with the following parties: R. M. Owen, president; R. A. Rainey, first vice-president, Entz Motor Patent Corp; D. C. Durland, of the Sprague electric, which is a General Electric property; Geo. F. Morrison, Edison Lamp Works, which is controlled by the General Electric, and R. H. Montgomery and Richard Swartout, representing financial interests.

McClurg Rubber Takes Over S. & M. Co.

Coshocton, Ohio, Jan. 14—Formal transfer of the property of the S. & M. Tire & Rubber Co., to the new McClurg Rubber Co. was made by Receiver E. A. Crawford, the consideration being $35,735.88. A journal entry was filed in common pleas court showing that the old stockholders may complete payment on their stock and receive shares of stock in the new company.

It was stated that the rubber plant will now commence operating to full capacity, with from forty to sixty employees, the number to be increased.

Bull Chairman J. I. Case Board—Davis New President

Racine, Wis., Jan. 17.—The reorganization of the official personnel of the J. I. Case T. M. Co., Racine, Wis., which has been going on for six months, was completed on Jan. 12 at a special meeting of the board of directors. F. K. Bull, for many years president, was advanced to a new position just created, that of chairman of the board of directors. W. J. Davis, treasurer, was elected president and will continue as treasurer. The complete list of officers and directors now is:

Chairman of the board, F. K. Bull; president and treasurer, W. J. Davis; vice-presidents, E. J. Gittins and M. H. Pettit; secretary, W. F. Sawyer; assistant secretary, Stephen Bull; assistant treasurers, C. J. Farney and R. P. Howell; directors, the officers and Frederick Robinson, W. E. Black, F. L. Hine and A. O. Choate.

F. K. Bull's father was one of the four founders of the big institution. He has been its head for nearly thirty years In the new position of chairman of the board, Mr. Bull will have complete supervision of all branches of the business. The new president, W. J. Davis, came to Racine from Marinette, Wis., five years ago to become president of the Manufacturers' National Bank. Two years ago he was elected treasurer of the Case company and now he takes the larger duties of president, being provided with two assistant treasurers.

Increase of Wis. Registrations

Madison, Wis., Jan. 17—During the first 15 days of 1916, 22,250 applications from private owners for 1916 licenses were received by the Secretary of State of Wisconsin. During the same period of 1915, the number of applications was only 9750. Only 6000 sets of plates have been issued thus far, because of the inability of the contractor for plates to make prompt delivery as specified. Permission has been given to operate under former licenses until new plates can be provided.

Overland Capital Raised to $75,000,000

Toledo, Ohio, Jan. 14—At a special meeting to-day of the stockholders of the Willys-Overland Co., this city, the proposed program to increase the capital stock of the company as outlined in The Automobile of Nov. 11 has been authorized. The new capital amounts to $75,000,000 and consists of $50,000,000 common and $25,000,000 preferred. The common stock has been increased from $25,000,000 and the preferred is a new stock issue.

This action formally approves the proposal outlined last November for the capital increase and also the issue of $15,000,000 new convertible 7 per cent preferred stock, which has been offered to common stock to the extent of 71½ per cent of holdings at 110 and to the holders of the old preferred stock on similar terms. The old issue of preferred has been called for redemption at 110. The company has outstanding at present $21,000,000 common stock.

St. Louis Chevrolet Raises Capital to $1,000,000

St. Louis, Mo., Jan. 12—The capital stock of the Chevrolet Motor Co. of St. Louis has been increased from $10,000 to $1,000,000 according to a statement filed with the Secretary of State of Missouri. About the same time a statement was filed by the Banner Buggy Co. showing a decrease in capital stock from $700,000 to $400,000. Russell E. Gardner, president of the buggy company, is also president of the local Chevrolet Co.

Canada Ford Makes $3,202,000

1915 Output 24,500 Cars—To be Raised to 40,000 in 1916

Detroit, Mich., Jan. 14—Earnings of the Ford Motor Co. of Canada, in the past year ended Sept. 30, 1915, amounted to $3,202,000, on an output of 24,500 cars. The company at present has outstanding $7,000,000 capital stock, of which $6,000,000 represents the recent 600 per cent stock dividend. Last year's earnings therefore are equivalent to 45 per cent on the increased amount of stock.

The output for the current year will be 40,000 cars. The present capacity of the plant is 60,000 cars.

The cash dividends paid by the company have amounted to $1,600,000, or an average of about 116 per cent per annum. This has been in addition to stock dividends.

The record of profits and production of the company is as follows:

Year	Production	Net Earnings
1915	24.500	$3.202,000
1914	16,000	2,022,000
1913	11,500	1,317,000
1912	6.500	1.065.000

800 Stockholders Hold Reo Shares

Lansing, Mich., Jan. 5—The shares of stock of the Reo Motor Car Co. are held by about 800 stockholders, according to Secretary-Treasurer Donald E. Bates, of the Reo company. Most of the holders reside either in Lansing or in Detroit and 15 per cent hold less than ten shares each. The par value of the Reo shares is $10. Ever since the company was started the control of stock has remained with the men who started it.

The capital stock, when the company was incorporated in August, 1904, was $500,000. It was later increased to $1,000,000 then to $4,000,000 and last December to $10,000,000. Of the $4,000,000 capital stock $1,000,000 was held in reserve in the treasury. Dividends were:

	Cash, Per Cent	Stock, Per Cent
1905	10	..
1906	37½	50
1907	86½	33⅓
1908	80	..
1909	60	100
1910	30	..
1911	3	..
1912	20	..
1913	10	..
1914	37½	50
*1915	35	100
11 years	409½	333⅓
Average per year	37¼	30

---

*Does not include regular quarterly dividend of 2½ per cent payable Jan. 1, 1916.

Since 1905 and up to the end of October, 1915, the total number of passenger cars made and sold by the Reo

Motor Car Co., was 72,050. The annual production was as follows:

Year	Cars
1905	864
1906	2,458
1907	3,967
1908	4,105
1909	6,592
1910	6,588
1911	5,278

1913	7,647*
1914	13,516**
1915	14,693***
Total, 11 years	72,050
Average per year	6,550

*For fiscal year of 11 months.
**For fiscal year of 14 months.
***For period of 10 months.

Seven Lansing Firms Paid Big Dividends in 1915

LANSING, MICH., Jan. 6—During 1915 seven local manufacturing concerns directly connected with the automobile industry, have paid to their shareholders cash dividends totaling 140 per cent and stock dividends totaling 206 per cent. The amount credited to each concern was as follows: Reo Motor Car Co., 35 per cent cash, 100 per cent stock; W. K. Prudden Co., 30 per cent cash; Auto Body Co., 25 per cent cash, 96 per cent stock; Auto Wheel Co., 20 per cent cash; Atlas Drop Forge Co., Bates & Edmunds Motor Co., and Reo Motor Truck Co., each 10 per cent cash.

Sheet Steel Parts Makers to Double Capacity

DETROIT, MICH., Jan. 17—The Holihan Mfg. Co., Twenty-first Street and West Jefferson Avenue, which makes sheet metal parts, such as gas tanks, flat and crown fenders, hoods and general stampings, is to double its plant. According to officials of the company business was 300 per cent better during 1915 than it was in 1914.

Ampco Re-elects Board

MILWAUKEE, WIS., Jan. 14—At the annual meeting of the stockholders of the American Metal Products Company (producers of "Ampco" bronze), the old Board of Directors was re-elected, being constituted as follows: Peter J. Weber, president; Henry C. Brelie, vice-president; Wm. J. Eberle, secretary and treasurer; Richard Gaertner, manager, and Charles E. Helm and August Littmann.

The officers reported that although the present plant was being worked to full capacity it was impossible to keep up with the demand, that orders on hand were plentiful, and that the many large orders pending absolutely necessitated the immediate installation of additional facilities.

Goodyear Rushes New Plants

AKRON, OHIO, Jan. 14—The new plants of the Goodyear Tire & Rubber Co., this city, are being rushed to completion. These will give the company a capacity of 20,000 automobile tires a day.

Ogren Expands To $1,000,000 Co.

Name Changed to Ogren Motor Works, Inc.—H. W. Ogren Chief Engineer

WAUKEGAN, ILL., Jan. 14—The Ogren Motor Car Co., has changed its name to the Ogren Motor Works, Inc., and has increased its capital stock from $25,000 to $1,000,000. The company this year will inaugurate an extensive expansion policy which includes the above increase of capital and the construction of a plant in Waukegan.

H. W. Ogren, designer of the car, has been appointed chief engineer and general manager of the new company which was incorporated under the laws of Delaware.

On Feb. 1 ground will be broken for a new plant in this city, which will cost $150,000, and as soon as the buildings are ready for occupancy the company will move from Chicago, its present location. The main building of the plant will measure 150 by 900 ft.

It is the intention of the company to continue the manufacture of its present model, a six listed at $2,500, and in addition to put on the market another type of six-cylinder car that will sell for less than $1,000. Production plans for 1916 call for the manufacture of 3000 cars.

The company is building two racing cars for a campaign next season. Tom Alley, has been engaged to pilot the cars in most of the races for this year.

Steel Lower—Oils Higher

NEW YORK CITY, Jan. 18—Market prices in general last week were subject to many changes. Bessemer and open-hearth steel dropped $1 a ton to $32 and $33, respectively, while a majority of the oils and lubricants saw small gains. Another important change and of much interest to the tire makers at the present time is the reduction in Para and Ceylon rubber prices. Last week the reductions of both grades amounted to 7 and 8 cents, respectively. Copper went up ¾ cent a pound in both electrolytic and Lake grades.

Tin has kept up its downward movement, which has reached the $41 mark per 100 lb.

The demand for automobile materials is at the present time very large and the manufacturers, as has been stated in previous issues of THE AUTOMOBILE, are having difficulty in procuring certain metals and other materials. It has been estimated that the crude rubber output during the current year will establish a new high record at 175,000 tons dry weight, worth over $260,000,000. The value of rubber is a fluctuating quantity, but it is estimated that the average wholesale price for the current year will be 75 cents per pound.

Approximately 131,000 tons of crude rubber were gathered throughout the world last year. As the big American consumers of rubber buy several months ahead, it is apparent that they are still working on lower-priced rubber. Even $1 a pound, while it represents an advance of 30 per cent for the year, seems low when contrasted with the average prices in 1910 for the two grades, viz., $2.18 for plantation, and $2.75 for Para.

Lion Tire and Rubber Corp. Formed

LAFAYETTE, IND., Jan. 14—The Lion Tire & Rubber Corp., this city, has been incorporated with a capital of $150,000 to manufacture automobile tires. The company has purchased the Heinze plant on Union Street where it will carry on its manufacturing. The incorporators are Ferdinand Dryfus, Thomas Follen, P. F. Freel, W. A. Klepper, R. K. Bedgood, H. J. Haarmeyer of this city; G. B. Smity of Pittsburgh; J. T. Cullen of Peru; Thomas Crane of Chicago, and Edward Taylor of Montmorenci.

The following officers have been elected: President, Ferdinand Dryfus; first vice-president, Thomas Follen; second vice-president, Edward Taylor; treasurer, P. F. Freel; secretary, H. J. Haarmeyer.

Tire Scrap	.05½	.05¾	.05¾	.05¾	.05¾	.05¾	+ .00¼

The output will be 200 tires a day and the same number of men will be employed. It is expected that the first tires will be ready for the market on May 1.

100,000 Studebakers for 1916

DETROIT, MICH., Jan. 14—The Studebaker Corp., has planned a production schedule for 1916 which calls for 100,000 cars. The factory has been running full capacity, and more than 5000 of the new models have been shipped since Jan. 1.

Studebaker Succeeds Swander

NEW YORK CITY, Jan. 14—C. D. Studebaker, who has been connected with the local branch of the Firestone Tire & Rubber Co., has been appointed branch manager to take the place of D. C. Swander, who becomes eastern district sales manager. H. Topping, who was Mr. Studebaker's assistant, has succeeded him as office manager.

Ohio's Chauffeur License Law Not Enforced

COLUMBUS, OHIO, Jan. 15—According to instructions issued by W. H. Walker, Ohio Registrar of Automobiles no attempt will be made to enforce the chauffeurs' license law in the State until the highest court finally passes on the question of constitutionality of the law. In a letter written to Joseph Cisan, Jr., examiner of chauffeurs at Cleveland the instructions are given that applicants for chauffeurs' licenses must be informed of the unsettled condition of the law and to discourage all chauffeurs from registering.

Security Prices Lower

General Motors Common Goes Up 10 Points—Rest of Market Apathetic

NEW YORK CITY, Jan. 19—Automobile and accessory issues last week were dull with the exception of General Motors, which picked up in price yesterday, reaching the 489 mark, just 24 points higher than Saturday's quotation. The rest of the issues showed few marked gains. Those stocks which have occupied more or less prominence on the Exchange during the last few months have lately shown a declining tendency, especially Maxwell, Overland and Studebaker. Last week Maxwell common dropped 3 points; Overland dropped 1 point; and Studebaker closed with a 2-point loss. In regard to Overland securities, the committee on securities on the New York Stock Exchange has ruled that all transactions in the common stock of that company be ex-rights Jan. 17, and that transactions in rights must be settled Jan. 19, when due bills must be redeemed. The right to subscribe at 102½ for new convertible 7 per cent preferred stock to the extent of 71½ per cent of the holdings expires Jan. 21.

Last week several small gains were made; Reo Motor Car went up 2 points as did Stewart-Warner common; White rose ¼ point; and Studebaker preferred closed with a 1-point gain.

A few of the drops are as follows: Chalmers, 5 points; Chevrolet, 4 points; International Motors common and preferred, 4 and 5 points; Peerless, 1 point, and U. S. Rubber common and preferred, ¾ and 1⅜ points, respectively.

Chalmers common featured the Detroit securities last week with a 10½-point drop. Continental Motor common went up 5½ points. The rest of the market showed small gains and losses ranging from 1½ to 3 points.

Pratt Leaves Pierce-Arrow

BUFFALO, N. Y., Jan. 11—J. Elmer Pratt, who has been sales manager of the Pierce-Arrow for seven years, has severed his connection with that organization. Mr. Pratt has not yet announced his future plans but is going to continue actively in the industry. He enjoys the country-wide confidences of all who have come in contact with him during his long years of service in the industry.

Shafer Leaves Flint Varnish

FLINT, MICH., Jan. 11—A. E. Schafer, who for the past two years has been associated with the Flint Varnish & Color Works as vice-president and general sales manager has severed his connection with that company.

Overland Talks for Dealers

CHICAGO, ILL., Jan. 18—During the week of the Coliseum motor car show Jan. 22-29, the Willys-Overland company will conduct a series of educational talks for dealers at Overland headquarters, Congress Hotel, at 3 p. m. each day of the show with the exception of the closing date, Saturday, Jan. 29. Henry H. Hower, of the Knight motor department will deliver the talks which are connected with the Knight motor.

Hoff Pullman President

Succeeds J. C. Schmidt—Co. Is Operating Plant at Full Capacity

YORK, PA., Jan. 14.—C. L. Hoff, general manager of the Standard Chain Co., this city, has been elected president of the Pullman Motor Car Co., to succeed John C. Schmidt, for the past four months the head of the Pullman company. The duties of former-President Schmidt, who is also president of the Standard Chain Co., having become too strenuous, is given as the cause for the change.

The Pullman company has embarked on one of its most successful seasons, the factory being operated to its fullest capacity. More than 600 men are now employed on the day and night shifts. Improvements have recently been made to the plant at a cost approximating $100,000.

W. F. Grove, for the past seven months connected with the Bell Motor Car Co. as general sales manager and factory superintendent, has resigned his position to become the head of the York Motor Car Co., a new organization established for the sale of Pullman cars exclusively. The company has located its headquarters at 217 North George Street, where a show and salesroom and service station will be maintained. A full line of automobile tires and accessories will be handled by the company. The district covered by the agency includes York, Adams and Lancaster counties. The York Auto Exchange was formerly the agency for the Pullman car in York.

Good Patents Often Unworkable

(*Concluded from page* 119)

inventor will still be deprived of the right to make the improved form of the device without the consent of the second patentee until the second patent expires.

Under these circumtsances, obviously the thing for the parties to do is to reach some business agreement, and this is usually the outcome, and it accounts in a large measure for manufacturing concerns holding a series of patents covering the development of the articles they manufacture. Often a single article, such as a spark plug will be covered by a half dozen or more patents, the earlier ones having broad claims on the particular type of plug, and the later ones going into the detail structure or perhaps to the process of manufacture of the plug or of a part of it, such as the porcelain.

Patents cannot, therefore, be segregated and held up individually as representing the product solely of the patentee; each is simply a step in the advancement of the art; merely the carrying forward of ideas previously expressed in broader terms, each patent being coupled with perhaps a dozen others, all of which are necessary to form the links of a chain of protection for a particular article of manufacture.

Licensing System for Dealers and Users Legal

NEW YORK CITY, Jan. 14—Holding that the Victor Talking Machine Co.'s system of price maintenance is legal, the United States Circuit Court of Appeals in New York has reversed the decision of the United States District Court. The Victor company brought suit against R. H. Macy & Co., this city, the complaint being in regard to its licensing system, by which dealers are licensed to sell Victor goods, and purchasers are licensed to use them. Each Victor machine bears a plate stating that it is not sold, but rented on a royalty under certain patents, and that it becomes the property of the user on the expiration of the patents. It is also provided that for violation of the license the machine may be taken back by the company and the royalty refunded less 5 per cent per year for use. By these provisions the Victor company is given full control until the expiration of the patent.

All-Steel Co. Elects New Board of Directors

ST. LOUIS, MO., Jan. 14—The All-Steel Motor Car Co., this city, has elected a new board of directors as follows: C. L. Smith, E. F. Stockholm, F. V. L. Smith, A. C. Duncan, John Hambeacon, Fred Smith and O. O. Trorlicht.

Brig.-Gen. E. J. Spencer has stepped down as president of the company, and it is stated that a new head will be selected at the next meeting of the board of directors.

The company has a capital stock of $400,000, of which half is paid in. Its plant in Macon, Mo., which will employ about 750 men, will be opened within sixty days.

Patterson and Burrows Are Partners

DETROIT, MICH., Jan. 12—Fred J. Patterson, formerly with the Ferro Machine & Foundry Co., and the Steel Products Co., both of Cleveland, and F. J. Burrows, who was buyer for the old Briggs-Detroiter Co., have formed a partnership as manufacturers representatives. Headquarters have been taken in the Kresge Building. The new firm has thus far secured the representation of the Toledo Steel Tube Co., the Hoosier Castings Co., the Curtis Screw Works and W. W. Wainwright & Sons.

Randall-Faichney Reorganized

Management Unchanged—New Company Takes Over Assets of Old One

BOSTON, MASS., Jan. 17—The Randall-Faichney Co. has been reorganized, the new company taking over all the assets of the old one including the building and good will of the business. The production of motor car accessories will be continued and a number of new products added. The management will be the same as during the past nineteen years and the heads of the various departments are practically the same. The officers of the company are: President, W. A. Randall; vice-president, G. H. Faichney; treasurer, Chas. P. Blinn.

[illegible] the main plant of the Ford Motor Co., Detroit, Mich., the total number of office and shop workers and officials now on the payroll of the company is close to 35,000. Of this number there are more than 24,000 men employed in the plant here. The office force, shop foremen, superintendents and inspectors aggregate another 1,000 men employed here in Detroit.

Fuller Plant Progresses

KALAMAZOO, MICH., Jan. 8—Progress is being made on the new plant of Fuller & Son Mfg. Co., this city. This company manufactures parts for automobiles and trucks. The new factory is of concrete and steel construction.

All Pennsylvania Automobile Employees Must Be Insured

PHILADELPHIA, PA., Dec. 24—On Jan. 1, when the new Pennsylvania workmen's compensation act goes into effect, everyone engaged in the automobile business, whether manufacturing or selling, will have to be insured, Compensation will be paid to employees on the basis of 50 per cent of their wages, the minimum being $5 and the maximum being $10, the length of time during which it will be paid depending on the nature of the injury. The premium rates are based on each $100 of annual payroll, as follows:

	Premium	Pub. Liability
Dealers, including executive and clerical force	$0.61	...
Automobile and body manufacturing (exclusively)	.74	$0.05
Automobile manufacturing (turning out automobiles complete)	.56	.03
Automobile manufacturing — assembling of manufactured parts only	.51	.03
Automobile radiator manufacturing	.74	.05
Automobile salesrooms (no garage or repair shop)	.33	.10
Automobile top manufacturing	.45	.05
Automobile windshield manufacturing	.56	.05

Los Angeles, Cal., Jan. 14—The Maxwell stock car, which established a record of 22,022.3 miles of continuous running for nearly 44 days under [redacted] him as office manager.

a

Ohio's Chauffeur License Law Not Enforced

Columbus, Ohio, Jan. 15—According to instructions issued by W. H. Walker, Ohio Registrar of Automobiles no attempt will be made to enforce the chauffeurs' license law in the State until the highest court finally passes on the question of constitutionality of the law. In a letter written to Joseph Cisan, Jr., examiner of chauffeurs at Cleveland the instructions are given that applicants for chauffeurs' licenses must be informed of the unsettled condition of the law and to discourage all chauffeurs from registering.

[redacted] Co., has [redacted]ors of the defunct Herreshoff Motor Co., will receive approximately 30 per cent of their claims. Thus far the trust company has paid 17 per cent in dividends. The claims filed totaled $213,967.92. This amount has been reduced to $95,570.49 owing to the discovery of duplications, withdrawals and disallowances. Claims totaling $616.85 are undecided.

Missouri's 1915 Registration 76,462

Jefferson City, Mo., Jan. 12—The total registration of motor vehicles in Missouri during the year 1915 was 76,462, according to figures made public by State officials here. The total amount turned into the State treasury from automobile registrations was $323,292.50. Applications for 1916 licenses are coming in at the rate of 2000 a day.

N. Y. Registrations Increased

Prediction of 275,000 Cars in 1916—31,400 Cars Licensed in Metropolitan District

New York City, Jan. 15—Predictions of automobile registration of 275,000 for New York State in 1916 are based on the rush for licenses during the last fourteen days. In the metropolitan district 31,400 automobiles have been licensed so far, as against 22,000 for the same period last year. Chauffeurs licensed number 11,125, against 12,000 in the first two weeks of 1915. Licenses issued to chauffeurs and automobiles so far this year have brought a revenue to the State of $285,000. Last year's revenue for the corresponding period was $202,000. For all of last year in the district 110,000 automobiles and 55,000 chauffeurs were licensed.

Pennsylvania Registrations for 10 Years $6,000,000

Harrisburg, Pa., Jan. 17—During the past ten years that the State of Pennsylvania has been licensing automobiles more than $6,000,000 in fees has been turned into the automobile division of the State Highway department. In 1906, the first year the State licensed automobiles, the State highway department received $42,460.42. In 1915, the tenth year for licenses, the revenue from motor vehicles was $1,665,276.50. The revenue by years has been: 1906, $42,460.42; 1907, $59,604.91; 1908, $83,920.69; 1909, $126,954.95; 1910, $321,989.12; 1911, $492,523.50; 1912 $597,723.19; 1913, $841,069.41; 1914, $1,184,646.50; 1915, $1,665,276.50.

A Traffic Court for N. Y.?

New York City, Jan. 14—A traffic court has been suggested for this city to settle all traffic cases. Mayor Mitchel, who suggested the plan, thinks that the present traffic difficulties of the city would be greatly lessened by the establishment of a special Magistrate's Court which would have jurisdiction over all traffic cases, or at least over as many as could be brought to one locality, and which would be tried as a class by themselves.

Kansas City Cars Gain 33 Per Cent

Kansas City, Mo., Jan. 1—The registration of automobiles in this city increased practically a third during the year 1915. Final registration figures in the city license department show that the last license for the year was No. 9774, issued on Dec. 24. As all licenses must be renewed on Jan. 4, no others were issued during the remainder of 1915.

The number of licenses granted in Kansas City since 1908 follow:

Year	Licenses
1908 (half year only)	391
1909	1,184
1910	2,194
1911	3,370
1912	4,359
1913	5,430
1914	6,721
1915	9,774

Eight-Story Overland Service Building in New York

New York City, Jan. 14—An eight-story warehouse and automobile service building for the Willys-Overland company at 521 to 531 West Fifty-seventh Street, through to 518, 524 and 528 West Fifty-eighth Street will be built. The plans call for a fireproof structure of reinforced concrete construction which will cost approximately $300,000.

Adds 1500 Automobile Cars

New York City, Jan. 14—The Lehigh Valley Railroad has placed orders for 1500 new automobile cars, which will be 40 ft. long, with 10-ft. double staggered doors, and will have both steel underframes and steel ends.

No Duty on Cars in Paraguay

Asuncion, Paraguay, Dec. 31—A law enacted Nov. 8, 1915, provides that unused vehicles, including automobiles and trucks, together with their accessories and spare parts, shall be exempt from import duty in Paraguay for a period of two years from that date. The suspended duty on motor vehicles imported into that country amounts to 62 per cent ad valorem, including surtaxes.

Better Trip Reset on 1916 Speedometers

(*Concluded from page* 138)

Like similar instruments it is a centrifugal type with a hand covering a dial reading up to 60 m.p.h. The trip mileage reads to 100 and the season mileage to 100,000. The latest Ford type, model FF-16, is mounted flush with the dash or the windshield strip, and sells for $15.

Garford

No changes have been made in the Garford instrument. It is a centrifugal type using a revolving ball race mounted on the main driveshaft. In this race are ½-in. steel balls held in place by an inverted steel cup. The inner surface of the cup is so designed that the centrifugal force of the steel balls which travel in radial cam grooves, raises the cup in proportion to the car speed. The movement of the cup is transmitted to the indicating needle. The Ford type lists at $12.50 and a larger size at $15.

Factory Miscellany

Peerless Tube to Add—The Peerless Tube Co., Bloomfield, N. J., will erect an addition to cost $13,100.

Tower to Build Trucks—R. J. Tower is planning to construct a motor-truck factory at Greenville, Mich.

Winton Building Addition—The Winton Co., Cleveland, Ohio, is erecting an addition to its plant at Berea Road, to be 80 by 300 ft.

Ward-Leonard to Build—The Ward-Leonard Electric Co., Bronxville, N. Y., will build a two-story plant, 100 by 185 ft., which will cost $35,000.

Jackson Top Co. Formed—The Jackson Winter Top and Special Body Works, Jackson, Mich., was recently formed in Jackson, Mich., to make automobile tops and bodies. Headquarters are at North Columbus Street.

Rochester Motors Factory—The Rochester Motors Co., Rochester, N. Y., is erecting a brick fireproof factory on Wren Street at an estimated cost of $9,000. The new structure will be 62 by 150 ft. and one story high.

Chester Rubber to Build—The Chester Rubber Tire & Tube Co., Chester, W. Va., will take bids in March for a plant to cost $720,000, including three structures, one 50 by 170 ft., another 40 by 75 ft. and the third 42 by 75 ft.

Ohio Motor Makes Lease—The Ohio Motor Mfg. Co., Springfield, Ohio, capitalized at $500,000, has leased part of the plant of the Winters-Coleman Scale Co. and will install machinery to manufacture internal combustion engines. The company is contemplating the erection of a large plant at Canton, Ohio.

Takes Over Automatic Screw—The Gas Motor Efficiency Co., Janesville, Wis., has taken over the business of the Automatic Screw Machine Co., Janesville, which has manufactured spark plugs for several years. The spark plug department will be greatly enlarged, while the production of liquid fuel vaporizers will also be increased.

Rockwell-Drake Plant in Plainville—The Rockwell-Drake Co. will begin the building of a one-story factory 100 by 130 ft. on a site in Plainville, Conn., recently purchased by Albert F. Rockwell, late of the New Departure Mfg. Co. The company, among other things, manufactures ball bearings and is now located at 78 Grove Street, Hartford.

Newcastle Co. to Sell Homes to Employees—The Greater Newcastle Co., with a capital stock of $100,000, has been formed in Newcastle, Ind., Jan. 10, those interested being President Walter E. Flanders and others connected with the Maxwell Motor Co. The purpose of the new company is to build, rent and sell homes to workingmen of the Maxwell plants.

35,000 on Ford Payroll—Including the main plant of the Ford Motor Co., Detroit, Mich., the total number of office and shop workers and officials now on the payroll of the company is close to 35,000. Of this number there are more than 24,000 men employed in the plant here. The office force, shop foremen, superintendents and inspectors aggregate another 1,000 men employed here in Detroit.

The Week in the Industry

Bissett Sales Mgr.—H. E. Bissett has become sales manager of the Michigan Specialties Co., Detroit.

Valentine Standard Tire Sales Manager—R. F. Valentine has become sales manager of the Standard Tire & Rubber Co., Cleveland, Ohio.

Kearney Heads Fisk Dept.—J. M. Kearney has been promoted to head of the service department of the New York branch of the Fisk Rubber Co.

Herold Joins Dodge Distributor—F. J. Herold has become general sales and service manager of Henry Bros., distributors of Dodge cars in Union, N. J.

Robinson Portland Kissel Mgr.—A. S. Robinson of San Francisco and one-time manager of the Los Angeles branch for the KisselKar, has been appointed manager of the Portland, Ore., KisselKar branch.

Stockbridge Succeeds Johnson—F. W. Stockbridge, sales supervisor in the East for the Winton Co., is new manager for the factory branch in Minneapolis, Minn. He succeeds J. S. Johnson, resigned after eleven years' connection.

Nerney Kissell Mgr. — H. W. Nerney, formerly one of the State representatives of the Pacific KisselKar branch, has been appointed manager of the San Diego house of the Pacific KisselKar, which was opened recently.

Jackson Joins Westinghouse—A. E. Jackson has been made Western representative of the automobile equipment department of the Westinghouse Electric & Mfg. Co., East Pittsburgh. His headquarters will be at 2007 South Michigan Avenue, Chicago.

Dealer

Minneapolis Chevrolet Makes Change—The Minnesota Motor Car Co., Minneapolis, which handles Chevrolet cars in the Northwest, has decided to combine its place of business with the assembling plant which the Chevrolet Motor Co. will build on a site to be announced about Feb. 1. The building is to be completed by July 15.

Gets Sunderman Carbureter for New York City—The J. F. Renfro Co., Inc., New York City, has been appointed exclusive factory distributor for the Sunderman safety carbureter, and the former local sales office has been discontinued. All shipments are being made from Newburgh, N. Y., where 500 carbureters are being made a day.

Motor Men in New Roles

Conlon Federal Truck Sales Mgr.—H. A. Conlon has been appointed district sales manager by the Federal Motor Truck Co., his territory consisting of the Middle West. He was formerly with the company's Boston and Providence headquarters.

Hare Resigns—E. S. Hare, for 10 years with the Philadelphia branch of the Commercial Truck Co. of America, has resigned and will be special representative of the Packard company in that city and New York. Mr. Hare is president of the Philadelphia Motor Truck Assn.

Magruder Makes Change — George Magruder, well known on the Pacific coast and formerly identified with the Northwest Auto Co. of Los Angeles, is now in charge of the repair department for Manley-Thompson Brothers in Tacoma, Wash., Chevrolet distributors.

Scharps Joins Silver—C. E. T. Scharps will assume on Feb. 1 the management of the wholesale department of the C. T. Silver Co., New York representative of the Overland and Peerless cars. He was formerly automobile editor and advertising manager of the Sun, New York City.

Sigwalt Resigns—H. T. Sigwalt, who has been with the Federal Motor Truck Co., Detroit, Mich., during the past 18 months as advertising manager, has resigned. He has been succeeded by G. W. Cushing of the Detroit Board of Commerce, where he was editor of the *Detroiter*, the board's weekly.

Van Horn Oakland Sales Mgr.—W. H. Van Horn, formerly of Findlay, Ohio, has been named sales manager of the Hannon Motor Sales Co. of Tulsa, Okla., handling the Oakland line in several counties of the State. Mr. Van Horn was the Oakland representative in Findlay.

Underberg Advanced to Branch Mgr.—C. H. Underberg, in charge of the Tacoma office of the Fisk Rubber Co. has been advanced to the post of branch manager in Tacoma. W. E. Bayless has been advanced to the position of northern coast district manager, with offices in Seattle. He will have charge of the territory in Washington, Oregon, Idaho and British Columbia.

Thomsen Sells Mitchell in Davenport—Henry Thomsen, Davenport, Iowa, has purchased the McGivern Motor Co., 115 Harrison Street, that city, and the concern will be hereafter known as the Thomsen Motor Co. J. A. Zeaman will be retained as general manager. The Mitchell car will be handled and supplies sold.

Deibler Mgr. for Newman—Harry Newman, Inc., 702 Grand Avenue, Milwaukee, Wis., Chalmers distributer for Wisconsin, upper Michigan and southern Minnesota, has appointed J. B. Deibler, Chicago, general manager. Mr. Deibler is a native of Berlin, Wis., and has been associated with the automobile business for fifteen years. He served the Haynes as Chicago branch manager for eight years and later took the Pope-Hartford representation. In 1901 he made the first long-distance run in a self-propelled vehicle in this part of the country, driving an old Milwaukee steamer from Milwaukee to Oshkosh and return. It was the first product of the former Milwaukee Automobile Co., one of the first motor car manufacturers in the United States.

Dealer

Washington Items — Stewart-Warner Speedometer Corp., Seattle, Wash., has opened a new service station at 1710 Broadway under the management of T. M. Hart. The Seattle station will be run under the name of the Stewart products service station.

Through the initiative of the Portland Garage Owners' Association a meeting has been called to organize a State association of garage men.

Agencies for Hudson cars in the State of Washington have been appointed as follows: Washington Auto Co., North Yakima; F. M. Powell, Everett; W. H. Bland, Bellingham; C. T. Scurry, Aberdeen; Walker's Garage, Hoquiam; Rasmussen's Garage, Kent; Howe's Garage, Port Angeles; E. C. Tew, Olympia; W. J. Bendennick, Bremerton; Raymond Auto Co., Raymond.

Two New Buildings for Minneapolis—Two new automobile buildings are to be erected, one by the Willys-Overland Co. and the other by the Northwestern Automobile Co. The latter is to be at Harmon Place and Willow Street, opposite the new building for the Hudson and Locomobile cars. It will house Saxon and Chandler cars. The former is to stand on a tract made up of a new purchase of land adjoining a tract bought from Bowman & Libby, Inc., when it took over the Northwestern distributing agency. It is one block from the Automobile Show headquarters.

The AUTOMOBIL

NEW YORK, JANUARY 27, 1916

Twenty-five cents a co
Three dollars a year

CHALMERS · MOTOR · CO
Detroit, Mich., U.S.A.

Quality First

This is the car that split the cluttered market wide open to make room for itself. The 3400 r.p.m. engine of the new Six-30 Chalmers touring car records the fastest engine speed of any American stock car. Price, $1050—yet it's as able a car as ever bore the Chalmers name.

Patent No. 1165861

Hudson Super-Six

An Exclusive Motor—80% More Efficient

A **Hudson dealer can say this about the Super Six:**

"My car has a motor 80 per cent more efficient than any like-size motor ever built before.

"It has won the world's stock-car records, against every size and price and type.

"By every test, by every sort of performance, no other motor comes in range of this. No Eight or Twelve can match it. The highest-priced car on the market cannot do what this car does."

YIELDS 76 HORSEPOWER

And that dealer can say this:

"This Hudson Super-Six develops 76 horsepower. The best like-size motors heretofore delivered 42.

"Think of 76 horsepower from a small, light Six. The size is identical with last year's Hudson Six-40. No cylinders added, no complications.

"All that increase—that 80 per cent—comes through wiping out vibration. It is power that other motors waste. It proves this Hudson Super-Six the smoothest-running motor in the world."

"I CONTROL IT"

He also can say, "I Control It."

For this is a Hudson invention, controlled by Hudson patents. No other car, whatever its price, can perform like the Super-Six.

World's Records Broken

All Records up to 100 Miles

At Sheepshead Bay, a 7-Passenger Super-Six—a stock car—made fastest time for a Touring Car, in official tests, under supervision of American Automobile Association.

100 miles in 80 min., 21.4 sec., averaging ***74.67 miles per hour,*** with driver and passenger.

Previous best stock car time was made with a multi-cylinder car carrying driver only.

75.69 miles in one hour with driver and passenger.

Two laps made at 76.75 miles per hour.

Standing start to 50 miles per hour in 16.2 sec. A new record in quick acceleration.

So this car has no rival.

Any man who wants superlative performance can find it in Hudsons only.

THE CAR WILL PROVE IT

The Hudson dealer can make these claims, and the Super-Six will prove them.

This vast reserve power, combined with lightness, does amazing things. And does them without evident effort.

Men have never seen such flexibility.

In quick response, the Super-Six has broken all the records.

But the great fact is that all these things result from utter smoothness. So riding is like flying in the Super-Six. Engine wear is reduced to almost nothing. And all this extra efficiency means that much power saved, that much fuel.

Combined with all this are six luxurious bodies. They were built by master craftsmen, without any stint on cost. No costly car has ever shown more elegance and beauty. So the Super-Six looks its supremacy.

Hudson dealers this year offer all these exclusive advantages. No man who wants a fine car can resist them. And any man who buys an old-type motor, even for one-third less, will in the long run pay more than the Hudson costs.

Don't you think that Hudson dealers are in an enviable position?

The AUTOMOBILE

Chicago Draws the Curtain

33⅓% Gain in Attendance Over 1915 at Opening of Sixteenth Show—Decorations a Great Success—80 Gasoline Car Exhibitors—7 Electrics—52 Stripped Chassis

An example of the Japanese decorations

CHICAGO, ILL., Jan 22—Chicago's sixteenth annual automobile show opened this afternoon promptly at 2 o'clock with the usual crowds waiting at the doors of the Coliseum and the armory as in former years, and within one-half hour the entire lower floors were filled, setting at rest any thoughts as to a possibility of waning interest in the automobile in the Windy City and in the great Mississippi valley that have for a couple of years been enjoying unparalleled prosperity due to bumper crops and war-time prices. To-day's and to-night's attendance has not brought a symptom of indication of waning interest; rather, the curve is shot upwards in keeping with automobile production, the price of materials, the price of gasoline and the price of tires. Official figures to-night show a paid attendance almost 33 1/3 per cent in excess of last year, with a much larger attendance of out-of-town dealers, many of whom have arrived days ahead of last year, the only reason for which is found in the present shortage of freight cars to ship automobiles from the factories to the dealer.

50% More Dealers

The freight car problem in itself is enough to warrant dealers hurrying up, but there is a little nervousness due to the difficulty of getting deliveries, the rising price of materials slowing this up. The prospects are that before the end of the week the registration of dealers will be fully 50 per cent ahead of last year. Those arriving early hope to get the early-worm percentage of deliveries.

A Japanese Garden

Chicago's four-building show, always renowned for its decorative effect, is up to standard, all four buildings having walls and roofs entirely covered, giving a Japanese garden effect, with pagodas, Japanese tea girls, and Japanese scenes forming the roof draperies, the gallery fronts and, in short, concealing every bit of the walls. The entire interior of the Coliseum, the Coliseum annex, the Armory and the Greer building are in reality scenes snatched from the Mikado's realm, with more realism added by Japanese lettering on all signs, excepting the miniature electric ones that hang above the accessory exhibits. There are huge Japanese pillars filled with electric lights forming the major effect on the main floors; myriads of bright-colored Japanese flowers on the mural draperies; Japanese arches, Japanese

INTERIOR view of Coliseum taken from one corner of the gallery, showing the sea of lights and the general scheme of decorations, huge illuminated Japanese lanterns, typical Japanese arches with the enormous circle, and Japanese screens on which the name of the exhibit is carried out in miniature Japanese letters.

One side of the First Regiment Armory, showing every detail of the decoration. The hanging round the gallery gives a good idea of the richness of the effect

va[illegible] a typical Mikado scene, as typical as if tak[illegible] the famous Gilbert and Sullivan opera.

A T[illegible]

It[illegible] show with all of the old-time Chicago sho[illegible] Pneumonia Alley connecting the Coli-se[illegible] long lines of demonstrating cars on Wa[illegible] the Coliseum, more long lines on Mic[illegible] of the Armory; demonstrating mot[illegible]tic makers filling the streets and carr[illegible] signs; hotels filled with exhibitors who[illegible] any of the buildings; and vacant stor[illegible] Avenue are covered with improvised elec[illegible] new accessories or car makers who coul[illegible] within any of the four buildings.

T[illegible] Chicago hotel accommodation was tak[illegible] before the show started, theaters are near[illegible] railroads are running beyond capacity, in [illegible] West is stirred up with the automobile's great[illegible] year.

This year's show is unique in the long list of sixteen annual exhibitions staged in the historic Coliseum, the scene of so many national political conventions and historic in many other regards. For the first time in its career the Chicago show has few additional cars over the New York show. For years Chicago has come forward with a score or more of new exhibitors not seen in New York; there have also been numerous late body ideas that were not ready for the Gotham exposition; there were always many new motors, and a host of other new components and accessories. This year there is only one brand new car uncovered, this honor going to the Champion from Wabash, Ind., a conventional block type four-cylinder chassis at $750. There are, however, a few makes such as Glide, Farmack, Sun, a new Detroiter body and a new Halladay, details of all of which have already appeared in these columns.

But One Miniature Type

For the first time Chicago is practically free of anything in the complete automobile partaking of the cyclecar, or motor buggy idea, the Gadabout being the only miniature type seen. In former years Chicago distinguished itself by the first and largest exhibit of motor buggies, then came other days when the cyclecar held the novelty stage, but to-day it is as conventional a show as ever staged, conventional cars, and conventional accessories.

Last year there was a crop of new eight-cylinder motors not seen at New York; this year there is not a new motor with the possible exception of Continental showing one of its recent six-cylinder models which is seen for the first time at a show this year, as Continental did not exhibit at New York. There are no new eights, no new twelves; in fact, this feature is in strong contrast with a year ago, when there was a veritable landslide of premature eights, which were not ready for New York but were hurried into readiness for Chicago. For the first time in its career, the Chicago show is more of a duplicate of the New York show than ever before, with the possible exception of some body styles not shown at the Grand Central Palace.

More Car Exhibitors Than at New York

When the show is compared numerically with the recent New York exhibition, it is discovered that there is one more gasoline car manufacturer exhibiting at Chicago, the total for the Windy City being eighty, as compared with seventy-nine at the Gotham display. There are also two more electrics at Chicago than at New York, the respective totals being seven and five. New York, however, leads in the total number of gasoline cars and chassis on display, having 307 to Chicago's 294. Last year Chicago had 254 gasoline cars and chassis on exhibition.

Electrics in Armory

Chicago is the greatest electric city in the country; it is known as the home of the electric and, as usual, has the center of the armory set aside as an exclusive electric exhibit. This exhibit is smaller than usual with seven different makes, showing in all twenty-two different cars and a couple of chassis. Contrasted with former years, this electric display is unique by reason of an entire absence of gaudy colors and interiors, it being tradition to work all the colors of the rainbow into some of the cars and the upholstery.

This year dark colors dominate, with gray-striped interiors. Waverley has the sole exception, being a brougham with broad-striped upholstery. The body colors are generally dark with the possible exceptions of the green Milburn roadster, a blue Ohio brougham and a Baker with dark-gray body and panels and light-colored wire wheels.

Wire Wheels and Cord Tires Popular

There is a preponderance of wire wheel equipment on the electrics, Detroit showing four out of five with wire wheels, Milburn two out of three, Baker and R. & L. two out of four, and Ohio, Woods and Chicago not showing any. The seven electric makers exhibiting are Baker-R. & L., Detroit, Ohio, Milburn, Chicago, Waverley and Woods. There is a preponderance of pneumatic tires, seventeen out of the twenty-four vehicles and chassis using them. Practically all of them are cord types.

Eights Gain 400%

Reverting to gasoline cars, this show serves well to demonstrate the rapid growth of the eight-cylinder car during the past year and also to show the progress made in twelve-cylinder types. There are forty-two eight-cylinder cars and chassis as compared with eleven a year ago, a 400-per-cent increase. The twelves not represented a year ago are now represented by eleven cars and chassis, the exact representation that the eight had a year ago. This coincidence suggests what the relative figures will be a year hence. Six-cylinder cars and chassis have increased from 109 last year

Accessory exhibit on the upper floor of the Coliseum Annex showing illumined Stewart-Warner exhibit in the foreground

The Japanese decorations of the Chicago show are carried out with extreme thoroughness and the effect is as handsome as could well be desired. Besides using many pieces of Japanese handicraft of many kinds, there is lavish employment of special paintings on a very large scale. These, combined with hangings and with garlands and sprays of artificial flowers, give the decoration a completeness seldom equalled.

to 135; and four-cylinder types have dropped from 133 a year ago to 106 at present. So is the trend of events outlined by THE AUTOMOBILE for Dec. 30, a dropping in the number of different makes of fours and the increase going to sixes, eights, and twelves, all gainers.

More Polished Chassis Shown

The present show demonstrates that the use of polished chassis as show attractions is on the increase, and that more of these can be used to advantage is indicated by the crowds constantly found around these exhibits, and particularly those where the demonstrator gives periodical lectures on the job. There are fifty-two chassis this year, as compared with forty-four last year and as compared with fifty-six at the New York show this year. The Studebaker gold-plated chassis now making the complete circuit is attracting many, as are such cutaway exhibits as Overland, Cadillac, Hupmobile, Reo, Saxon, Chalmers, Marmon, Stearns, Buick, Chandler and others. A tabulation contrasting the car exhibits of the present show with those of former years shows those concerns that rely on chassis exhibits.

Five-Passenger Bodies Lead

The Chicago show offers interesting contrasts with New York in body exhibits, and, while there are scores of bodies seen at New York and also at Chicago, there are always many different styles seen at the Coliseum. In the high-priced field New York invariably leads Chicago, many of the Chicago jobs savoring more of the utilitarian type. The open five-passenger type is still a leader, with sixty-four different styles shown. It is closely followed by fifty-seven styles of six- and seven-passenger designs. There has been a big gain during the year in the closed types, such as detachable winter tops, touring sedans, etc.

Eighteen Demountable Tops

There are eighteen demountable winter top styles as compared with one a year ago, when Kissel, the pioneer in this design, held sole sway. The West is appreciating this type of body, the demand being so great that nearly a dozen Chicago dealers and distributors have added body-building departments for the production of these winter types. The sedan type has increased but little, from seven a year ago to ten this season, these figures, however, not truly representing the increase in these types, as several dealers are exhibiting sedans in their salesrooms, due to lack of space in the exhibit space at the show.

Town Cars Gain

The town car following has increased very perceptibly during the year; in fact, Chicago has made rapid strides during the past year as a closed-car town. This closed-car demand is not local to Greater Chicago, but visiting dealers speak generally of the increased use of the automobile throughout the winter and the natural increase in demand for closed types. Limousines are not making gains; in fact, they are a little behind a year ago. Coupés have made little progress. Thirty-two different makes show wire wheels on all or some of their show cars, this being over 40 per cent. Cord tires are on sixteen different makes. In other words,

How the Japanese effect was worked into the accessory section

20 per cent of the exhibitors are showing cords on some or all of their cars and chassis exhibited.

Commendable Variety in Colors

From a body color viewpoint the present Chicago show is the brightest in the long line of sixteen annual exhibitions. Manufacturers are displaying commendable judgment in not making the show too much like a morgue by having everything in black. During the past fall THE AUTOMOBILE has carried on a consistent campaign for more color in car bodies, on the ground that black is one of the poorest body colors, being the easiest to dirty and the hardest to keep clean.

Color Options Increasing

THE AUTOMOBILE has made a canvass of car manufacturers on this question of car color, and the figures show that color options are rapidly increasing, not only with the high-priced makers, but many medium-priced car manufacturers are realizing that it is often possible to sell a car with a color option that would not be sold without it. Some dealers selling cars listing at under $1,000 have during the past fall instituted the plan of repainting bodies on new cars, giving the buyer several options, together with such additionals as slip covers and tire covers to match at an additional cost of $100 or thereabouts. Many sales have thus been made that otherwise would have gone to higher-priced cars giving some color options.

Brightness Without Gaudiness

Standing in the gallery of the Coliseum and looking over the couple of hundred cars on the main floor, the scene is much more brilliant than in former years, and, while more brilliant, it is not that useless gaudiness of former shows, but, with a few exceptions, the colors are practical colors and the interior finish and upholstery are feasible for general use.

Large-production manufacturers, such as Overland, Buick, Studebaker, Maxwell, Dodge and Reo, almost invariably have dark colors exclusively. Black dominates, but there are examples of dark greens and a few dark blues.

In the galaxy of color at the show Velie leads in novelty with three special show cars—one in red, one in white, and one in blue—a publicity scheme that is immediately apparent yet effective as a show exhibit. Among the other exhibits, the grays predominate. These are of all shades from gunmetal tints to battleship hues and to others much lighter. The broad striping usually found on them is absent this year.

In the brighter colors, reds, oranges, yellows and creams are popular. There are many maroons, many wine-colored bodies, and several combinations of cream and chocolate tints. Mercer has a bright yellow, while Scripps-Booth, Stutz and Case have orange-yellows. There are a few whites that are more for show purposes, such as Paige, Inter-State and Hudson, these generally having the broad black-and-white-striped upholstery.

Many Have Color Options

Looking next at color options given by makers, it is seen that the option policy is making good headway. There are nearly ten concerns that offer a wide range of colors, these including Packard, Winton, Locomobile, Mercer, White, Fiat, Pierce-Arrow and Mitchell on its closed cars.

Stutz shows bright colors on all models—two reds, a yellow, and a blue. This company gives six color options at a slight extra cost, these colors including maroon, gray, ultra-marine blue, white, and battleship gray in addition to those on exhibit.

National is a believer in colors, and for an extra price gives a choice of five, including gray, blue, cream, white and maroon. Scripps-Booth offers four colors: Black, gray, royal blue and English biscuit.

There are many concerns offering two or three color combinations. Thus, Oakland has green, gray and blue; while Chevrolet, Oldsmobile, Saxon, Buick and Westcott, have two each, at extras ranging from $25 to $50.

Other Standard Colors

Among some of the standard colors other than black being offered at present are: Chandler, blue; Marmon, blue; Kissel, blue; Studebaker, blue; Cadillac, Reo and Haynes, green; Willys-Knight, blue, and Paige, blue. These concerns offer other color combinations at extras that extend from $30 to $100.

Some color schemes seen at the show which tend to show the effort to get away from black are: Marion, four maroon cars; Cole, two greens, a red and a light yellow; Auburn, one dark green; Pathfinder, one yellow, one red, and two dark types; Lexington, a gray, a green, and a red; Hollier, a dark red and a black; McFarlan, a dark maroon; Premier, two grays and a green; Briscoe, a green, a cream, a red, and a light brown; Apperson, a blue, a gray, and a maroon; Moon, a gunmetal, a gray and a black; Chalmers, two wine-colored styles; Hupmobile, a gray, a dark brown, and two blacks; Marmon, grays; and those showing dark types, some blacks and others very dark greens are Elcar, Austin, Paterson, Allen, Detroiter, Glide, Grant, Metz, etc.

Taking first the gasoline cars it is found that eighty makers of this class of cars are represented as compared with seventy-nine at the New York show. Two hundred and ninety-four chassis are on display at the Chicago show as against 307 at New York, these being divided in such a way that the six-cylinder types lead with 135, the four-cylinders ranking second with 106 and the eights and twelves numbering forty-two and eleven respectively. New York had 136 sixes, 108 fours, thirty-nine eights and thirteen twelves. Of the 209 chassis shown at the Chicago show, fifty-two are stripped.

Two hundred and forty-two body types are shown. Of these 187 are open cars, sixty-five being five-passenger, fifty-seven six- and seven-passenger; thirty-three two-passenger; twenty-three three-passenger and ten four-passenger. In the closed car group fifty-five models are exhibited, seven being coupés, ten sedans, eighteen demountable tops—these include two-, three-, four-, five- and seven-passenger capacities—ten limousines, one landaulet, five town cars and two berlines. Putting these figures in the balance with New York, Chicago leads in the touring car class of exhibits by four, in demountable tops by three, in coupés by one, and in berlines by one. New York was ahead of Chicago in roadster types, having seventy-seven as against Chicago's sixty-six. In the cabriolets New York had five—a lead of three—in limousines, eleven—a lead of one; in landaulets, three—a lead of two. In the town car types they were even, each having five.

There are forty more gasoline cars on display to-day than there were at the 1915 show. One hundred and thirty-three fours were shown last year, as against 106 this year. Six-cylinder models show a material gain over last year, when only 110 were exhibited, compared with 135 this year. As an evidence of the gain in popularity of the eight it may be said that there are forty-two chassis being shown, whereas, only eleven were at the 1915 show. Of course, the twelves, being a 1916 development, no comparison is possible with other years.

More touring cars were displayed at the 1915 show than are to be found on the floors of the Coliseum, Greer Building and Armory to-day, although the difference is but one. Of the roadsters there were only forty-two last year, compared with sixty-six this year, but this is accounted for largely perhaps by the fact that three- and four-passenger bodies come under roadsters this season. In the other body types little difference is to be found in numbers as between the 1916 and 1915 Chicago shows.

The use of wire wheels seems to be on the increase, since thirty-two makers out of the eighty represented here are showing some, if not all, models so equipped. Of this thirty-two, twenty-three are Houks, four Rudge-Whitworths, two Freyers, or F. & W.'s, two Universals and one is Spanger. This shows that 40 per cent of the makers now are using wire wheels as stock equipment, or offer the purchaser an option, sometimes at a slight increase in price.

Cord tires are found on some of the models of 20 per cent of the manufacturers showing at Chicago. These are not stock on all models of all the makers exhibiting them, but are found predominating among sixteen separate exhibitions at the Chicago show. Of these sixteen, ten are Goodrich Silvertowns and six Goodyear cords.

Chicago Has Salon Show For First Time

CHICAGO, ILL., Jan. 24—A new thing in Chicago motor car circles is the Salon which opened Jan. 24 at the Auditorium Hotel. Although such an exhibition has been held for several years in New York at the Astor during show week, this is the first year that a similar affair has been staged in Chicago. The promoters are confident of the success of the venture, and seemed well pleased with the number of visitors during the opening hour.

Though naturally on a smaller scale, the Salon is similar in its scope to that held in New York this year. It includes several American cars as well as the foreign types. Those exhibiting are White, Simplex, Brewster, Peugeot and Lancia. The Salon has always been regarded as a high class body show, and the thought in exhibiting in Chicago is to get such an event started, because it is very certain that there is a place for it in Chicago.

Therefore most of the bodies on view at the auditorium are special designs that reflect the skill of the body makers. One of the White chassis carries an especially attractive Sedan upholstered in tapestry and having the new V fronted windshield that lends an unmistakable touch of class. One of the Lancias is also a closed type of Sedan design which is built with a very low roof to give a rakish appearance, this effect being accentuated by the slanting windshield.

A. C. H. Test Perfection Heater

A CERTIFICATE has just been issued by the Automobile Club of America covering a test made on the Perfection heater manufactured by the Perfection Spring Service Co., Cleveland, Ohio. The object of the test was to determine the effect of the heater on the power, fuel consumption and back pressure of the motor and to note the temperature of different points of the radiator surface.

The Perfection heater consists of a heat radiating element having six copper tubes connected to cast iron headers at each end. A casting which is clamped around the exhaust pipe between the motor and muffler and which contains means for by-passing a portion of the gases through the copper tube radiator is connected to the radiator by a flexible tube. In the casting is a butterfly valve which serves the double purpose of catching some of the exhaust gases and of shutting off the heater when its use is not desired.

Five runs were made on the motor with the heater on, off, with valve open and valve closed and a check run with the heater off again. The conclusions showed that the power output and the gasoline consumption of the motor were not adversely effected by the use of the heater; the back pressure was reduced when the heater was attached and its control valve opened; the back pressure remained the same as it was without the heater when the control valve was closed; the temperature was substantially the same in the center and outer tubes of the radiator.

Only One Quite New Car at Chicago

Ten Cars Shown for the First Time Contain Only One Surprise—Several Modifications in Design Noted on a Few Others

AS it was anticipated, there has never been a Chicago automobile show that differed so little in its exhibits from the New York exhibition. Not a single well-known manufacturer had a surprise to spring and there was not even an additional eight or twelve, to be found in motor form alone. Thus a review of the new cars at Chicago is mainly a list of the features of those few which have been altered in some small particular since their announcement in the summer or fall of 1915 when they were mostly described fully in THE AUTOMOBILE.

Of course, on the occasion of the Chicago show a number of cars are expected which on account of the lack of space or for other reasons did not appear at the season's opening in New York. Consequently it is not surprising to find at the Coliseum this week ten productions which have not been unveiled to the public gaze previously. These include the Monitor, Paterson, Detroiter, Glide, Dort, Halladay, Elcar, Farmack, Elgin and Gadabout. All of these have been made known to the public through descriptions in the trade papers and some of them are makes that have been on the market for a long time, such as the Monitor, Paterson, Detroiter, Glide, Halladay, while the Dort is a year old, and the Elcar is the product of a concern which has been delivering motor cars for many years, though the name is new. The Farmack and Elgin are making their initial appearance at the Chicago show.

In addition there is one car which has come unheralded to the Chicago exhibition, this being the Champion, produced by the Champion Auto Equipment Co., Wabash, Ind. The car is of the conventional small four type in most respects, but is featured by a special tire inflating arrangement such that any two of the tires can be pumped up at the same time while the car is on the road.

Though we are getting our first actual view of these cars, several of them have been described and illustrated in the Dec. 30 and Jan. 6 issues of THE AUTOMOBILE, among these are the Paterson, which is unchanged from its original announcement, the Glide, the Dort, Farmack and the Sun.

Champion Has Unique Tire Pump

Offering the most unusual feature of any car at the show is the new Champion, a small four which has an arrangement designed to pump the tires while the car is under way on the road. This arrangement consists of a diaphragm type of pump, mounted on the motor and driven from the front-end timing drive. From the pump air is carried to a distributing box on the dash, and thence to each of the four wheels. The air is led through metallic hose and the connection to the tire is through a stationary collar on each. The collar is fitted with hydraulic packing between the stationary portion and a rotating drum upon the wheel. A metal hose from the rotating drum to the tire valve completes the connection.

The distributing valve on the dash is so arranged that any one or any two tires may be inflated. It also is fitted with an automatic blow-off valve which whistles when the pressure reaches a designed amount, and prevents any more air being forced into the tire. The pump is thrown into operation by pulling a lever on the dash.

So far as the car itself is concerned it is a conventional small four, having a 3¾ by 4¼ in. block engine as a part of the unit power plant, a single plate clutch and three-speed gearset completing this unit. Carburetion is provided by a Schebler instrument and ignition by a Dixie magneto. A two-unit starting and lighting system is supplied, the drive is of the Hotchkiss type through cantilever rear springs and a floating rear axle. The axle is a Peru make and the motor is a G. B. & S. build. Roadster and five-passenger touring cars are offered at $750, the wheelbase being 110 in., and tires are 32 by 3½. The car is the product of the Champion Auto Equipment Co., whose factory is at Wabash, Ind. Present plans are for the production of 5000 cars during the coming season. One feature of the car is the fact that the tires are manufactured by this concern. They are called Perfection tires and use an asbestos fabric instead of the conventional cotton fabric.

Brief Details of Other New Cars

The Sun is a production of the Sun Motor Car Co., Buffalo, N. Y., and is a new light six with the popular 3 by 5-in. cylinder dimensions. It has Remy electric equipment, a dry-plate clutch, and Hotchkiss drive. Fuel is fed by the vacuum system, and the wheelbase is 116 in.

The Elcar is a conventional type of four-cylinder car with a five-passenger roadster body, selling at $775. It is made by the Elcar Carriage & Motor Car Co., Elkhart, Ind. It has a 3½ by 5, four-cylinder motor in which the intake valves are in the head with the exhaust valves on the side. The gearbox is in unit with the motor and the Gemco axle is employed.

The Paterson is a six-cylinder appearing in five- and seven-passenger bodies, selling at $985 in five-passenger form. The parts are standard, being a Continental motor, Warner gearset, and a Weston-Mott axle. The wheelbase is 117 in. and the tires 32 by 4.

The Farmack likewise has been described previously. This is a four, selling at $865, in five-passenger touring or roadster form. The 3½ by 5 in. motor is distinctive in that it uses an overhead camshaft as well as overhead valves. The Elgin is a six at $845 as a five-passenger touring car or a Clover leaf roadster. The Falls motor is 3 by 4½ in. block cast, the wheelbase is 114 in. and the tires 32 by 3½.

The Dort is a four, using a 3¼ by 5 in. block motor, unit power plant, cone clutch, cantilever rear springs. It lists at $650 as a touring car and $540 as a roadster. The electrical equipment is Westinghouse.

The Glide is a six at $1,095, with a demountable sedan top at $200 additional. It uses a 3 by 5-in. block Rutenber motor, Westinghouse electrical equipment, and Hotchkiss drive

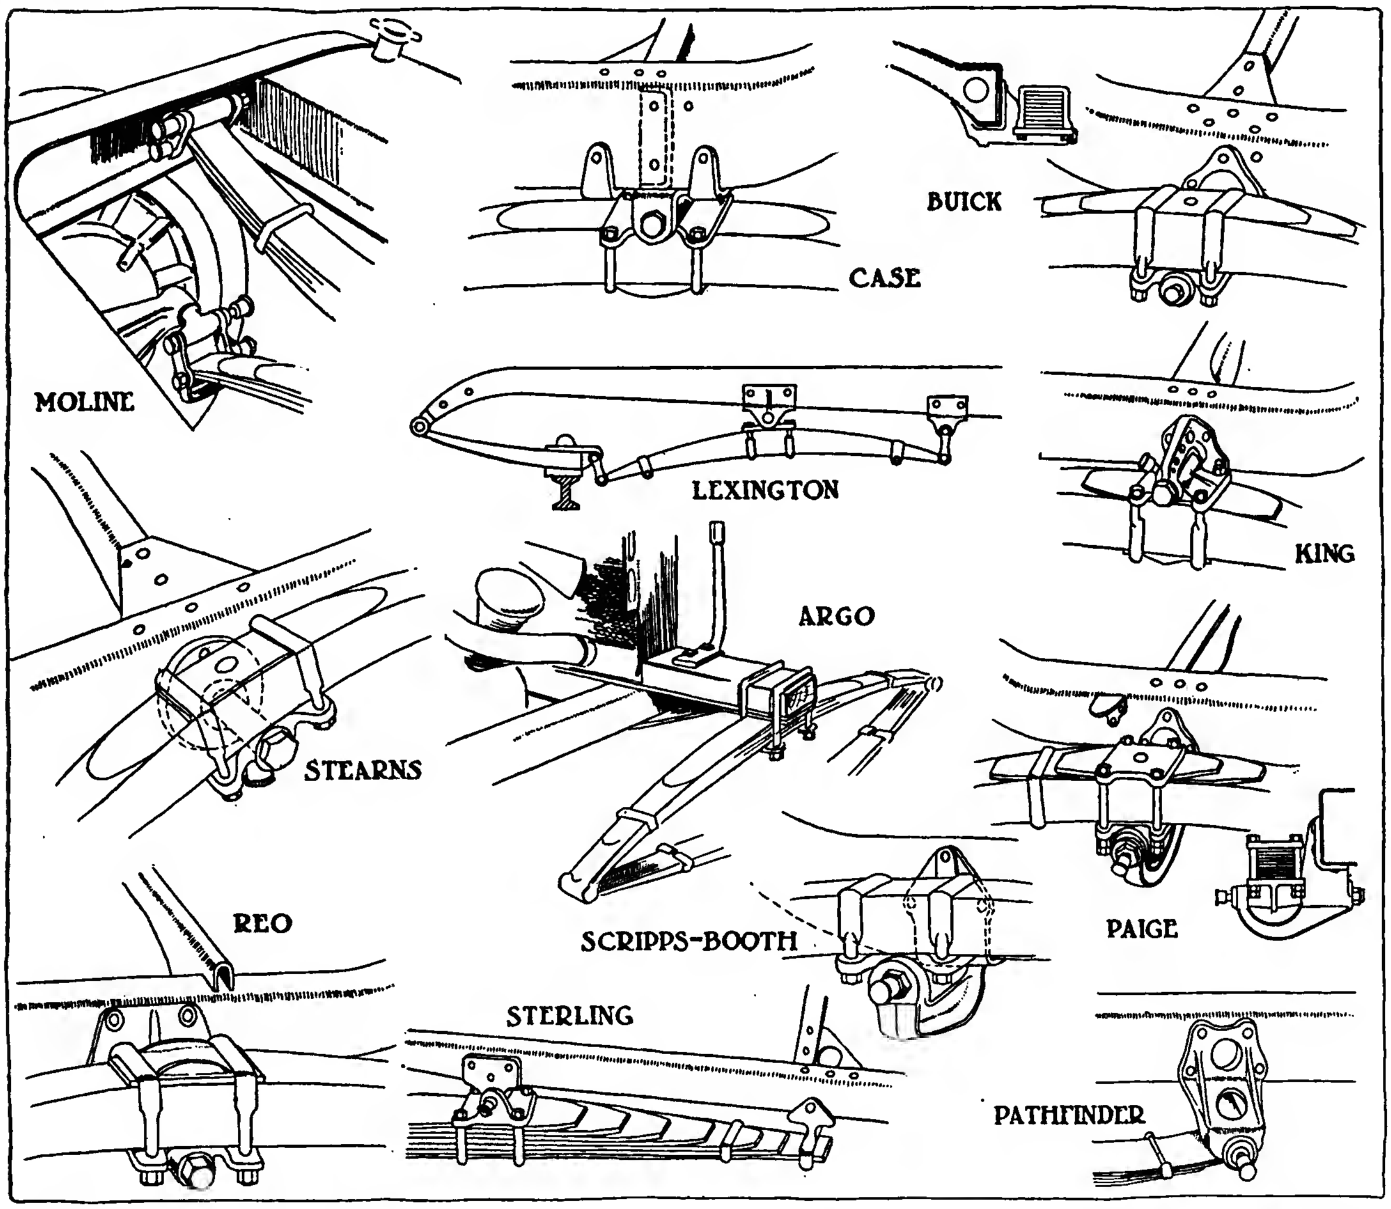
A new model of the Halladay has been produced within the past few weeks. This is a small six less in size and price than the model R which was the single model scheduled previous to the first of the year. The motor is practically the same as the 3 by 5 in. Rutenber employed in the large model, but the wheelbase is less, being 118 instead of 122 in. and tires are 33 by 4 instead of 34 by 4. In general desig the new model is the same as the model R, employing Stewart vacuum fuel feed and a Stromberg carbureter, floatin axles, pump cooling, and so on. This is made by the Barle Mfg. Co., Streator, Ill.

The Detroiter has produced a new six, which is known a the 6-45 and has a six-cylinder Continental-Detroiter moto of 3¼ by 4½ in. dimensions. It sells at $1,098, with a very modern double-cowl touring body. A long, sloping hood, slanted windshield, hooded radiator and other features of up-to-dateness are incorporated. Some of the major specifications are: wheelbase, 118 in.; tires, 33 by 4; 18-gal. gasoline tank feeding through a Stewart vacuum-gravity system; Auto-Lite, two-unit cranking and lighting system; Hotchkiss drive through semi-elliptic underslung rear springs; and floating, ball-bearing axle. In addition to a very full list of stock equipment, special equipment is offered in tonneau windshield, Moto-Meter, and wire wheels.

There has been a slight change in the size of the Monitor six since it was announced earlier in the winter. This consists in the increase of the bore of the motor ¼-in., so that it now is 3¼ in. The stroke remains at 5 in. This six of the Cummins-Monitor Co., Columbus, O., is known as the model N and sells at $895 as a five-passenger tourist. A roadster is offered on this chassis and there also is a four-cylinder model Monitor, known as the model R, which sells at $795.

The Gadabout is one of the very smallest of the cars on exhibition, and it also is one of the lowest in price, listing at $385 without electric lighting and cranking, or $485 with such additional fitting as electric equipment speedometer, clock and work light. It is made by the Gadabout Corp., Detroit, Mich.

Points made in favor of the Gadabout are the low weight, economy of first cost and operation and ease of handling and the mechanical design is carried out on these ideas. The motor is a Sterling four, 2⅞ by 4 in., with Atwater Kent ignition. The axle is a semi-floating type with gearless differential. An open, leather-faced cone clutch is used and the service brake is interconnected with the clutch pedal, the emergency brake being operated by a second pedal. The wheelbase is 104 in. and the tires are 28 by 3 in. The stock body is a two-passenger, though three-passenger bodies are made to order. An option of wire wheels is offered.



FEW parts of detail automobile construction vary more than the spring mountings, and the above sketches, made from cars at the Chicago show, illustrate these variations. Some engineers think it necessary to brace a frame very strongly by a cross rail at the point where the spring bracket is attached while others make no such provision. There is a slightly growing trend towards the use of a very wide frame so that the rear springs may go beneath it instead of to one side. Cantilever springs may have the middle pivot pin either above or below the spring, the two methods being used about equally. The eight cantilever sketches show all typical mountings of both varieties.

Accessory Section Features Component Parts

Motors, Axles, Transmission Parts and Springs Better Displayed at Chicago than in New York

CHICAGO, Jan. 22—Each of the two big automobile shows invariably claims a number of accessory and parts makers that the other does not list among those present. Some of these with a more specialized distribution of their product figure that either one or the other show best meets their field, and do not go into the one which they believe does not help them materially. There are still others which are somewhat local to the show in which they exhibit, such as, for instance, a concern in Chicago that might be the western distributor for a product. Instead of the factory, which we will assume is in the East, exhibiting, this representative takes care of Chicago.

Thus when we come to the Chicago show we find that there are this year about forty names in the accessory division that were not to be found at New York, although some of the faces that were to be found on the upper floors of the Grand Central Palace in the Metropolis are missing here. These range anywhere from the miscellaneous accessory exhibitor to the maker of castings, and heavy component parts such as motors, axles and gearsets.

Chicago has always been recognized as a great rendevous for dealers from all parts of the country at show time, and this may have some bearing on the fact that so many chose the Windy City in preference to New York. Chicago is more centrally located and is easier to reach from all sections, and so here you will find men from the Far West, from the South and from the North as well as the East. Accessory makers seeking distribution points are therefore especially alert to the advantages of being housed in the show buildings here this week.

It is interesting to note some of the big accessory names that are here for the show, and which did not appear at New York. Among them are the Remy Electric Co., the Warner Gear Co., the Continental Motor Mfg. Co., the Waukesha Motor Co., the Tuthill Spring Co., the Hess Spring & Axle Co., and many others.

Following are presented some of the accessories which visitors at the eastern exhibition were not privileged to see on display.

Two Good Motor Exhibits

There are two good exhibits of motors which were absent from New York. Although it is not exactly a new engine, having been in production for some time, the Continental little six known as model 7W, made by the Continental Motor Mfg. Co., Detroit, makes its premier appearance at any show. It is a clean-cut design with dimensions of 3¼ by 4½ in. The displacement is 223.95 cu. in., and in general the engine follows out recognized Continental six-cylinder practice with the cylinders and upper part of the crankcase in one piece and the head detachable. The valves are on the right, and of course completely housed in. On this side are also the centrifugal water pump and provision for either generator or magneto drive on the extension of the pump shaft. On the left rear side are bosses intended for the attachment of an electric starting motor to drive through gearing with the flywheel, and this unit together with the carbureter, which bolts directly to the cylinder block, are the only accessories on the left, although the breather and oil gage have been placed here in convenient positions.

The front of the motor is arranged to be hung from a forged cross piece, and the rear supports are a part of the housing of the flywheel, the crankcase bolting to this housing direct.

Another motor exhibit was that of the Waukesha Motor Co., Waukesha, Wis., who have several models of truck and tractor motors including a 3½ by 5¼ in. four of very compact design, a 4 by 5¾ in. four type with cylinders in pairs, a 4¼ by 5¾ in., a 4½ by 6¾ in., and a 4¾ by 6¾ in., these all being fours similar in design and adapted to certain truck requirements. The 3½ by 5¼ in. type is a good example of modern truck design, and is especially recommended for commercial cars ranging from 1 to 1½ ton capacity. It is a block-cast type with cylinders and upper crankcase a unit and the head detachable. Practically complete enclosure of all parts is a feature. Valves are on the right and the carbureter on the left, bolting direct to the cylinders, so that the distribution to the cylinders is through cored passages within the casting.

Several Component Exhibits

Apart from motors, there were a few other component parts well displayed, among them being sundry Warner products made by the Warner Gear Co., Muncie, Ind. A novelty among them is a new two-pinion differential designed especially for lighter types of cars. Instead of the usual four differential pinions, this gets along very nicely with two, and thus simplifies the construction as well as making it lighter. The Warner company also manufactures a line of steering gears designed to meet the requirements of different types and weights of cars. Model S 37 F is particularly adapted to many of the lighter types of cars on the market, and possesses the features of adjustability of rake, full worm wheel, quadrant above the steering wheel, and horn button in the center.

Another of the Warner products is a complete series of gearsets to meet any requirements. These are made adaptable to unit power plant constructions, cars in which the gearbox is located amidships, and types in which it is coupled up to the rear axle. A new example of the latter form is the model T 43, which is a very compact three-speed construction intended for cars from 20 to 25 N. A. C. C. horsepower. Similar to this but designed to bolt to the motor is the model T 46 intended for cars ranging from 20 to 30 hp. Warner also specializes in both multiple-disk and cone-clutch construction, particularly where they are intended for unit power plant installation.

Tuthill springs made by the Tuthill Spring Co., Chicago, are well displayed and in the construction of these springs the main feature of design is the absence of a center bolt to keep the spring leaves in position. Instead a bump is given the leaves and between the bottom leaf and the spring pad of the axle a wedge shaped plate is interposed; thus the combination with the spring bolts at either side of the bump prevent any movement of the wheels with respect to each other, and make a strong construction to relieve them from any possibility of center bolts shearing or weakening of the spring leaves due to drilling for such bolts. The Tuthill company has published a booklet listing all standard makes of cars and indicating the style and model of its springs adapted to each model of each make of car. For instance, for the model D 44 Buick, the price is $8.25.

Hess Has Axle Exhibit

Hess axle products are advantageously displayed at the show. These are made by the Hess Spring & Axle Co., Cincinnati, Ohio, and include designs incorporating both the spiral bevel gearing and straight bevels. They all have pressed steel housings, most of them ridged outwardly by webs in the top and bottom of the housing. A good example is the model 214, which is intended for the car weighing from 2800 to 3600 lb. It has spiral gears and the differential is arranged for convenient adjustment to the large opening at the rear. With these axles double-internal expanding cam-brakes are used, with the brake operating rods and equalizers incorporated in the unit.

Front axles of various sizes and shapes are also manufactured as well as any design of spring. The front axles are all of the I-beam drop-forged type, while the rear designs are made either in semi-floating, three-quarter, or floating construction, and are equipped with both ball and roller bearings.

A somewhat unusual exhibit is that of the Advance Felt & Cutting Co., Chicago, who make a big line of felt products for the use of motor cars, besides marketing a machine for the use of dealers and jobbers which cuts felt washers to the proper size for any car. It consists essentially of a regular hand-punched press and comes complete with a full set of dies, being adaptable to cutting leather, rubber or asbestos as well.

Die Castings Displayed

Die cast parts of all descriptions, some of them being exceedingly complicated, are displayed by the S. H. Franklin Mfg. Co., Syracuse, N. Y. This concern concludes that die castings are no longer an unknown quantity, now taking their place with stampings, screw machine parts, forgings and so forth in the construction of many well known instruments. The Franklin concern makes them of various white metal alloys which are forced into steel molds under pressure. The work is so accurate, a finished article results which eliminates practically all machine work. One of the specialties in this line is die-cast bearings, which present an entirely finished appearance without any subsequent machining.

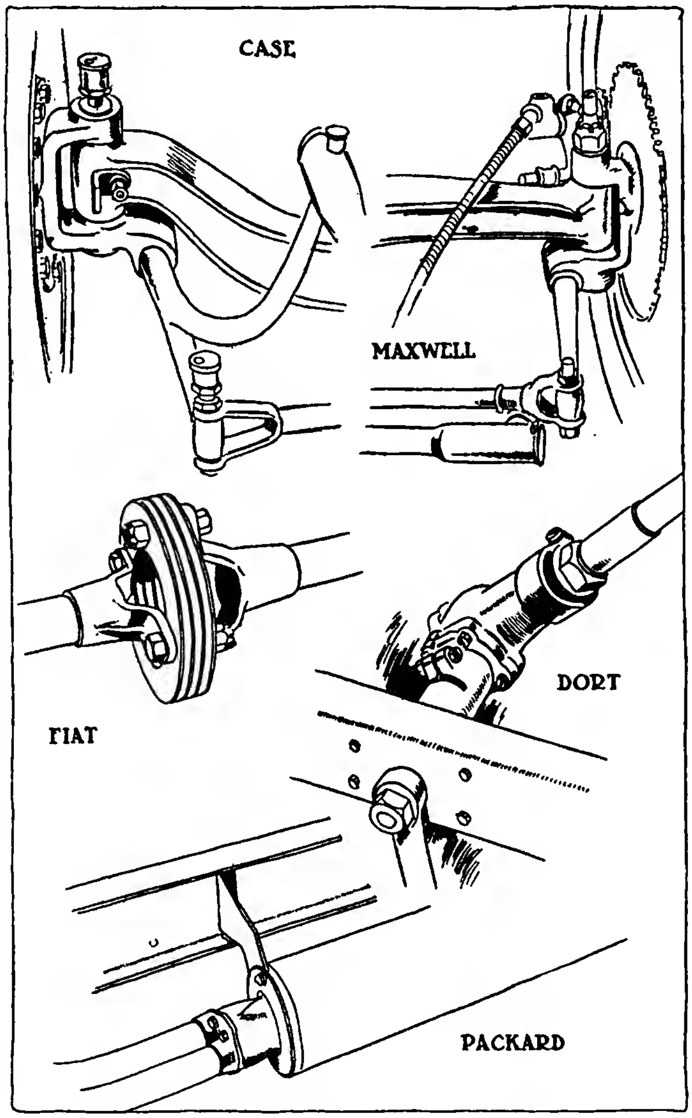
A large variety of automobile castings are to be found in the educational exhibit of the William Cramp & Sons, Ship & Engine Building Co., Philadelphia, Pa. These range anywhere from bearings made from Carson's white brass or Cramp special bearing bronze, to crankcases, rear axle worm driving gears and steering gears.

The Benjamin Electric Mfg. Co., Chicago, is featuring among other electric specialties a line of horns, both of the vibrator type, and of motor driven construction. The vibrator horns have been on the market for several seasons and the motor-driven horn is new this year. The motor operates on five to six dry cells and the principle is that of a rotating member striking the diaphragm to make an especially loud warning. This horn is made either for mounting outside or under the hood, and sells for $7.50, finished in all black enamel and 50 cents more when it is black and nickel.

The vibrator types are in several shapes for both under hood and outside attachments and range in price from $4 to $6, depending on the size and finish. In their construction the vibrating electromagnets strike the diaphragm to make the signal. A magnetic horn designed for Fords is also produced, intended for installation so that it can utilize some of the excess current furnished by the Ford magneto. It costs $3.

The American Bronze Co., Berwyn, Pa., is showing various examples of its bearing materials and castings made from from Non-Gran bronze. The special feature of Non-Gran aside from the composition of the material is that it is sold in assortments of different sizes of bars to meet the requirements of the garage.

The F. A. Ames Co., Owensboro, Ky., have some new detachable tops for Ford roadsters and touring cars. These are of the cloth material construction, arranged so that the doors not only hinge nicely but the attachment of the body is very rigid and there is a good fit between body and top and windshield, preventing any air or water from leaking in. The roadster type weighs about 100 lb. net and sells for $60, while the touring car type weighs 150 lb., and sells for $97.50.



THESE few sketches of cars at the Chicago show illustrate some neat points of design. Two examples of the European form of front axle with the yoke on the wheel spindle instead of on the I-beam are the Case and the Maxwell. Besides being simple these are both extremely strong designs. A novel universal coupling is used on the Fiat between the clutch and the amidships gearbox, this combining both leather and thin spring steel. Each piece of leather is separated from the next by a steel lamination, so adding to the rigidity of the coupling. The Dort has a steering gear that can be set for rake when assembling the car by means of a simple split housing with a pinch screw lock. On the Packard twin-six there is a single muffler, and a very neat and simple piece is used on the muffler end to receive the two pipes.

Italy Developing Aeroplane Engines

New Model Cars Also Being Built—Experimental Work Unaffected By War*

By W. F. Bradley

Chivibirri 16 Fixed Cylinder Aviation Motor

ALTHOUGH the tendency is to decrease the time spent on road tests by more complete dynamometer tests, manufacturers being pushed by the special chassis test tax, it would be impossible to convince a Turin automobile engineer that road tests are unnecessary. He would point to the mountains surrounding his town, the tops of which are capped with snow in the month of August, to the Mt. Cenis pass, more than 10,000 ft. high, he would remind you that the Stelvio, the highest mountain road in the world, is only a few hours run from Turin, and he would smile at the idea of any indoor test replacing this natural testing ground. In addition to the ordinary factory test service, the English branch of the Fiat Company maintains its own tester at the Turin factory, who must test every chassis on the road before it is shipped abroad.

Milan Has Several Factories

Apart from Turin, the only Italian town having automobile interest is Milan, where there are about 5000 people directly employed in the automobile industry. The most important factories are Bianchi and Isotta-Fraschini. Smaller firms are Zust, Otav, Junior and Alfa, this last mentioned being the old Darracq concern, but having now no connection with the French and English Darracq companies. Alexander Darracq, the founder of the Darracq Company, but now totally disconnected with that concern, is in Milan running a couple of ammunition factories supplying the Italian government. The Bianchi establishment is particularly interesting and complete. The output comprises bicycles, most of which are absorbed by the army, motorbicycles, light cars, trucks and armored cars.

Each of the European countries has its own "school" of automobile design as distinctive as the art schools of the different nations. A typical Italian car, for instance, with all nameplates removed, could not be confused with a typical French, English, Belgian or German machine. The standard Italian machine is a four-cylinder of 100 by 140 mm. (3.9 by 5.5 in.) bore and stroke. Sixes, eights and twelves may be considered as non-existent, at any rate at the present moment. Cylinders are a block casting with all external piping abolished. The biggest Fiat ever built—7.48 by 10.5 in. bore and stroke—is as clean a block casting as the smallest standard motor made. There are no detachable cylinder heads; indeed the tendency is to make the water header on the top of the cylinders an integral part of the casting. This is done by Scat and also by Newton, an English firm with an Italian factory. It is admitted that the casting is more difficult, but the advantages claimed are a neater looking job and the abolition of a joint.

In most cases the exhaust manifold is cast integrally, a conspicuous example being the Nazzaro. L-head is standard, naturally with enclosed valve stems. Intake manifold is an integral part of the casting. In many cases the throttle and the jets are within the casting, only the float chamber being external. Water pumps are also combined in the cylinder casting, a good example being the Spa. Thermo-syphon cooling is not used. The crankcase breather is cast in the cylinders to avoid an external pipe. Lubrication is forced feed to all bearings with no external pipes other than the lead to pressure indicator.

Unit construction is generally employed, the motor being mounted direct to frame members, without a sub-frame and without a mud-pan. Gearbox is aluminum casting with arms encircling and forming a well for the clutch, generally multiple disk type; cone clutches are not in use. Four speeds are invariably employed. Hotchkiss drive is not used, the typical Italian car having one-piece axle housing and torque tube with forked end. This is a two-piece stamping bolted or welded together. Axles are full floating; wheels are detachable but not of any definite type—wood, wire spoke, steel spoked and steel disk all being used. Springs, semi-elliptic; brakes, water-cooled when cars are for Italian service; dashboard invariably of cast aluminum. Electric lighting and starting very commonly employed, the two-unit system being preferred.

New Models Are Being Produced

The war having had no adverse influence on the experimental departments of Italian factories, new models have been produced and tendencies are observable. There is not going to be any serious breakaway from the four, but one very important firm has a twin six almost ready and will put it on the market in 1916. It is more than probable that other firms having carried out experiments with twin-six aviation motors will also produce twelve cylinders as a model de luxe. Bore will be rather less than 3 in., and stroke about 5 in. The feeling is that the mass of motorists will be satisfied with fours and that the twin-six can only be considered as a superfine car. There are no indications of the appearance of eight-cylinder motors in Italy.

A more general move is toward the adoption of small, light two- and four-seater cars, to be put on the market at a popular price, fully equipped with electric lighting and starting. This is an adoption of American ideas, but emphasis is laid on the fact that the cars will have the high-grade finish which always has characterized Italian cars. Bianchi has led in this direction with a small four-cylinder model of 2.4 by 4.3 in. bore and stroke. The car is really a reduction of the bigger models made by this firm, with three instead of four

---

*This is the last of a series of articles by the Paris correspondent of The Automobile, who has just concluded a careful examination of the Italian industry.

speeds, the gearbox being on the front end of the torque tube. The car is sold as a two- and a four-seater, with electric lighting and starting. As a two-seater it has been very extensively adopted by the Italian army, officers making use of it as a runabout.

Another important Italian firm has two new small car models ready and will doubtless put them on the market early in 1916. These are important, both on account of the standing of the concern and the changes in design which have been adopted. The two models have respectively four-cylinder motors of 2.44 by 3.9 and 2.75 by 5.1 in. bore and stroke. In each case cylinders and crankcase are one casting, but cylinder heads are not detachable; base chamber is an aluminum casting. Motor is L-head type, with enclosed valve stems, adjustable single-chain drive for camshaft and magneto shaft, and thermo-syphon cooling.

Thermo Syphon Cooling Grows

The change from pump to thermo-syphon is important, for it is likely that it will be extended to a larger model of 3.3 by 5.9 in. bore and stroke, and its sponsors are a firm always maintaining that a pump was an essential part of a motor equipment. It is admitted that it is a difficult task to produce a thermo-syphon cooled motor which will be satisfactory in the hot plains of Italy and on the Alpine passes, but the firm claims that with careful design and such good foundry work as they can produce in Italy the pump can be abolished. The change has evoked a lot of discussion and an important bet has been made that no standard car, of any make or any horsepower, with thermo-syphon cooled motor, can get over the Stelvio pass, in the Alps, under its own power. The bet has been taken up by the maker of this car and will be decided during the hot weather next year.

These two new cars have unit construction, four speeds, bevel gear drive and double internal brakes on rear wheels; there is no brake on the mechanism. Electric lighting is fitted for both cars, the larger of the two having electric starter. The generator is mounted over the flywheel housing and partly projects through the aluminum dash, the projecting end being covered by a detachable plate. The starting unit is alongside the motor, just below the crankcase hanger, and engages with a gear cut in the face of the flywheel. The smaller model has a lever starter, with rack and pinion in the gearbox. This type of starter is already in use on the Newton 2.7 by 5.5 in. four-cylinder light car and is very successful. There is no additional external mechanism, for the change speed lever is made use of, with an additional notch on the change speed quadrant, and the vertical rack is mounted in one corner of the gearbox. Only a quarter turn of the motor is obtained at each stroke of the lever, but owing to the ratio between the rack and the pinion on the lay shaft, the motor is turned over at a much higher speed than it is possible to spin it by hand.

The general specification of these cars is practically that of some of the popular American cars. The differences are in the use of a smaller high-speed motor and a better finish—sand blasted castings, polished aluminum dash, burnished bolts, parts machined all over. This adoption of American ideas is not likely to be confined to one or two Italian firms. Some leading members of the industry in Europe are in favor of closely copying the cheaper American cars, with no more finish than is usually given the $500 car. On these lines it is claimed that they could manufacture and sell cheaper than American cars could be imported. Others, as in the case described above, are willing to adopt the general idea, but refuse to sacrifice the detail finish they have been accustomed to give their high grade cars.

Apart from the small car and the twin-six motors, tendencies are toward detail refinements. Pointed radiators are coming more into use, with the top rounded off so as to harmonize better with the hood. Lancia is now making use of a wood fan made by an aeroplane propeller specialist; it is claimed that a propeller of this type is much more efficient than the average cast aluminum fan.

A greater use than ever is being made of aluminum dashboards, but the latest type is a hollow dash within which all the instruments and wires are carried, leaving both faces perfectly neat. With the general adoption of electric lighting and starting sets the wiring of a car is increased, and an untidy appearance is given to what would otherwise be a perfectly clean-line chassis.

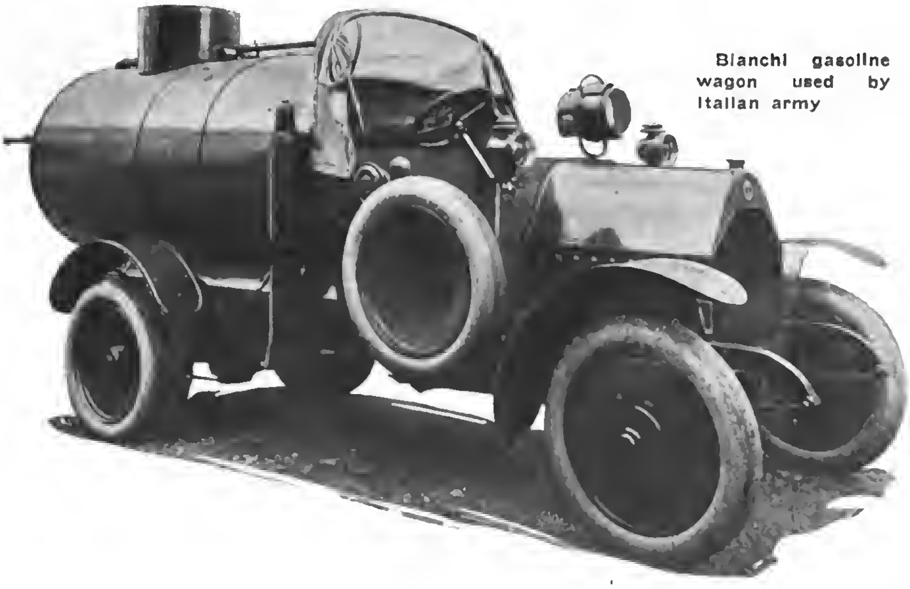
Nazzaro has a very fine example of the hollow aluminum dash with all wiring encased, the only uncovered parts being about an inch of the end of each ignition wire as it connects up to the plug. The Italians have held back on chain drive, but are now coming to it more strongly, the most popular type being a triangular drive across crankshaft, camshaft and magneto shaft, the adjustment being on the magneto pinion.

There are no worm driven cars in Italy, practically every maker having straight bevel. Fiat has recently taken up the Gleason spiral bevel gear and appears to be thoroughly satisfied with it; it is understood that this type of gear will be used for all their pleasure cars.

Few Aluminum Pistons

There is comparatively little use of aluminum pistons by Italian makers. Yet the Italian industry is not at all a stranger to this metal. Aquila-Italiana started using aluminum alloy pistons on all their cars as far back as 1911. They were used on all models up to 3½-in. bore, with hollow connecting-rods having walls only 0.85 mm. thick. Aquila-Italiana has adhered to aluminum pistons up to the present. Fiat has carried out a lot of experimental work with aluminum alloy pistons and is at present making use of them on all their six-cylinder aviation motors, which have a bore of 4.7 in., and on all racing motors. Aluminum alloy pistons were used in the set of Fiat cars run in the last French Grand Prix, when no trouble whatever developed with the pistons. At the Chiribirri factory, one of the small Italian firms doing much experimental work, I was shown a 40-hp. aviation motor with aluminum cylinders and cast-iron liners, built in

Italian Bersaglieri on Bianchi Truck



Bianchi gasoline wagon used by Italian army

1912, and flown in that year. This firm makes aviation engines and an original light car with cylinder dimensions 2.5 by 3.8 in. bore and stroke, the pistons of which are aluminum alloy. In other factories it was stated that experiments had been carried out with steel, cast iron and aluminum alloy pistons, with the final retention of cast iron. In several cases it was stated that it had been impossible to overcome piston slap, even with a scraper ring fitted. As the result of these experiments one firm grinds its cast-iron pistons slightly oval. The head is cylindrical, the ovalization increasing as the skirt is reached.

Aeroplane Motors in Demand

Italian factories have only been interested in aviation motors since the war broke out. Previous to hostilities there was no encouragement to make aviation motors; supplies were allowed to come in from France, Gnome securing the greater portion of the business. At the present time the Gnome Company has an important factory in Turin and is working exclusively for the government on rotary cylinder and fixed eight-cylinder all-aluminum water-cooled motors. All the factories, however, are now making aeroplane engines and a number of V-types are being produced. Fiat is at present interested in the six-cylinder vertical water-cooled type, with inclined overhead valves and a single overhead camshaft. Cylinders are of steel, and of course separate, with a sheet steel waterjacket, common to each pair of cylinders. This motor is of the same general type as that built in France by Renault and Lorraine-Dietrich.

Lancia is building twin sixes with horizontal valves, giving a combustion chamber of the type used for a number of years on Delage racers, and on the car which won at Indianapolis in 1914. Spa has built eight-cylinder V-motors, eight horizontal opposed with two crankshafts and only four combustion chambers, 10 cylinder Anzani motors, and six-cylinder vertical type with steel cylinders, sheet metal jackets and overhead valves. The Diatto Co. has taken up the Bugatti aviation motor, which has six separate steel cylinders welded together and surrounded by a copper water jacket. There are four vertical valves per cylinder, with a patented mechanism by which a single cam operates direct on a pair of valves. Isotta-Fraschini is interested in both six- and eight-cylinder aviation motors of the vertical water-cooled type. Nazzaro is building Anzani type motors. As in France, the aviation motor work will tend to bring the twin six motor into greater prominence and it is expected this will cause its adoption for car work.

Cars For Egypt Must Have Special Carbureters

ACCORDING to articles published in the Egyptian *Gazette*, the climate is an important factor to be taken into consideration in connection with the market for automobiles in that country, carburetion, lubrication and cooling being affected by the atmospheric conditions. Facilities for long distance touring being lacking in Egypt, the type of vehicle most in demand is that best suited for town traffic work.

Higher mileage per gallon of fuel may be obtained than in other countries due to the higher temperature and greater humidity, the latter condition frequently receiving inadequate attention in determining carbureter adjustments. It has been noted that in a large percentage of the cars imported it has been necessary to cut down the fuel supply to a considerable extent before satisfactory working results were obtainable, marked economy accompanying this change. This weakening of the mixture, however, frequently causes trouble with radiation due to the same climatic conditions which make the carbureter adjustment necessary.

The essentials of a perfect carbureter for use in Egypt are: It must deliver a fairly rich mixture with the control lever set at the nearly shut position to insure easy starting; the strength of the mixture should be maintained during the process of getting under way and as this progresses, gradually weakens, until the weakest possible mixture on which the engine will pull well at 20 to 25 m.p.h. is being delivered, at which point the control lever and throttle should be about half through their distance of travel. It is stated that it is impossible to secure these results from the original carbureter owing to the use of automatic control of the air supply which prevents attaining the exact conditions required. Mechanical control of the air supply in proportion to the fuel supply is therefore necessary.

Since engine temperatures in Egypt are far higher than in the countries where the principal motor oils are made and tested, an oil that gives perfect results in other countries quickly becomes far too thin, with the result that abnormal quantities must be used and even then such thin oil does not coat the cylinder walls sufficiently to give perfect compression. Hence it gets past the rings and is burned, giving an unnecessary carbon deposit with resultant loss of power. The obvious remedy is to use a far heavier grade of oil and by so doing to increase compression with a corresponding increase of efficiency and economy and the considerable abatement of smoke and carbon. The same applies to gearbox and differential greases which soon become little better than oil, after a little running.

Special attention must be paid to the efficient protection of all working parts against the sandy dust which prevails. Universal joints should be carefully covered and frequently examined and an especially well-fitting undershield to the engine should be insisted upon, as should that type of spring shackle which is drilled for lubrication and fitted with a screw-down grease cup.

As regards springs the usual standard types do not seem to be a success and a very long and light suspension combined with shock absorbers seems to give the best result.

Working Out the Rolls Royce Brake

Experiments Showing Many Unexpected Effects with Different Materials Led to Adoption of Compressed Asbestos on Special Type Shoe

By Chas. J. Booth
(Engineer, Rolls Royce, Ltd., Derby, England.)

I RECENTLY carried out a series of comparative tests of various brake materials which I think should prove of general interest. The purpose of these tests was to obtain reliable and impartial data *re* the many fiber brake lining materials now on the market and to make a comparison between them and the older metal-to-metal types.

It may perhaps be as well to state at this point that these tests were made and this article written without the cognizance of the manufacturers of any of the materials mentioned and that personally I have no financial interest in any of these concerns; the statements I shall make are therefore quite unprejudiced and may possibly be not endorsed by the makers in their entirety, but are the results of my own experience and tests.

Cast Iron for Brakes

The old standard practice of using a brake having cast-iron liners working on steel drums, for many years reigned supreme in the motor car world as the best combination that it was possible to use, although such a brake it must be admitted has several minor drawbacks or faults. One of these is the noise emitted when the brake is applied, which varies from a low grating noise to a high pitched scream, and another being the tendency of the brake to suddenly seize instead of allowing itself to be gradually applied.

I tackled this problem very seriously some years ago and made a number of tests with varying grades of cast iron, which only seemed to prove that the best I could do was a compromise between two evils. The screaming and the seizing seemed to go together and were always associated with a hard and close grained cast iron, which, however, had excellent wearing qualities.

By using a softer iron the screeching and seizing disappeared, but so did the wearing qualities; I used numerous grades of iron till I got to a point where all tendency to seize was eliminated and the noise reduced to an almost unnoticeable low grating sound, but the iron was now so soft that the liners appeared to powder up and wear so rapidly that they could be completely worn through in a week's severe testing.

Experiments with Steel

I also tried varying the steel brake drums, comparing case-hardened drums with others not hardened, and others cooled out at various temperatures, but I got exactly similar results, that is, noise with hard drums and wear with soft ones, but the seriousness of brake drums needing replacement leaves the designer no choice but to make these as desirable as he knows how.

The policy therefore dictated by these tests was to use a liner made of a medium grade of cast iron as a compromise between rapid wear or noisy and screamy brakes.

I should also add that I found that an excessively hard liner also had a tendency to wear ineffective through taking a very high polish and becoming glazed, and it was also obvious of course, that the harder the liner the greater would be the wear taking place on the drum, which I repeat is a serious point to be avoided as the very reason for the existence of a brake liner is of course, to have the wearing part of a brake easily and cheaply removable.

Lubricated Brakes

Seeing that the noise referred to above is simply the natural result of rubbing the rough surface of the cast iron without a lubricant, the next point that occurred to me was that if the brake were lubricated then it might be possible to use the hardest liners without the attendant disadvantage, but tests in this direction did not tend to impress me very favorably. It is well known that a little thick oil applied to a harsh brake will temporarily make the brake beautifully smooth in action and silent, but the effect almost immediately wears off if the brake is applied hard.

If on the other hand a liberal supply of oil is applied in the first place in order to last longer, one finds the brake practically useless when first applied, with perhaps, dangerous results in an emergency.

The position therefore forces us to consider brakes which are automatically lubricated; this, however, is a complication which like all other complications must in my opinion justify its existence by very definite benefits, which in my experience they do not.

One method is to use a number of oil grooves on the brake which are connected to an oil well, or sometimes to a drip feed lubricator, these each have their disadvantage, the principal one being that if the brake is not used for a lengthy period it is flooded and useless when next required, hence the designer is driven to elaborate the scheme so that the amount of oil used is controlled by the number of times the brake is used. The most usual type employed is one in which an oil-way is uncovered or a valve opened every time the brake pedal or lever is operated, thus insuring a supply of oil simultaneous with each brake application, but I have not yet myself tested a system which was free from unexpected floods of oil occasionally; for instance in negotiating congested traffic one is constantly depressing the brake pedal without actually applying the brake, and consequently the brake is swamped with oil and inefficient when it may be urgently needed.

Another serious objection to lubricated brakes is that, with prolonged application the oil is liable to be burnt entirely away and, unless the pull on the brakes is reduced proportionally (which is too much to expect a driver to do) the brake suddenly seizes.

It is a most desirable thing to have the efficiency of the brake absolutely constant, and this can be most readily obtained by using an unlubricated brake, and my own experience compels me to indorse the policy of those manufacturers who go to some trouble in their brake designs to prevent the possibility of any oil leaking or being thrown on their brake drums.

Using Phosphor Bronze

Having apparently exhausted the possibilities of cast iron, my next move was therefore to look out for some other material that might combine in a greater measure the desirable features of efficiency, silence and durability, and phosphor bronze struck me as being possibly a suitable material. I therefore made several tests with this and similar alloys, but I was not very favorably impressed by the results, the action of this material appeared to vary, not with its hardness, but with the speed of the revolving drums; at very slow speeds for instance the efficiency of the brakes is good, but accompanied by much screaming noise, and at fast speeds the brakes are much less efficient, but are more silent: at very high speeds they were ineffective. They appear to wear well, but develop a rough surface after much use; they also roughened up the surface of the drum.

This material cannot be used successfully with a lubricated brake as the co-efficient of friction is reduced to a point which makes the brake valueless.

Copper for Liners

I also tried brake liners made from hard copper, these in contradistinction to phosphor bronze appear to work better when lubricated, but were rather uncertain in their action although they were very silent and smooth when oiled. Like phosphor bronze their surface appeared to roughen up after use, when used dry; in this condition they also screamed very badly and seized.

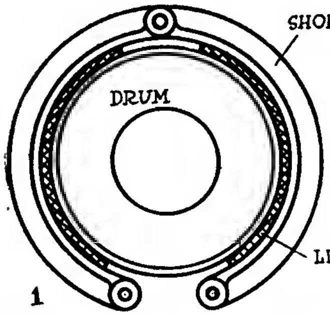
Woven Asbestos Materials

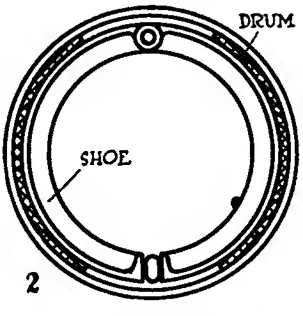
My only hope seemed to lie in trying some of the many brands of woven asbestos brake linings. I made up some brakes using liners having sections of both cast iron and asbestos, but the latter appeared to compress in use, leaving the cast iron to take all the load.

I was greatly disappointed at these results and discontinued the tests, concluding that there was nothing to better the use of cast iron brake liners, and for a time I left the subject of brakes entirely alone. Fairly recently, however, I became impressed by the very rapid rise to popularity and universal use of these asbestos fabrics and decided to give the matter further consideration.

The first thing I then discovered was that the wearing qualities of these fabrics had been greatly improved so that they had better durability. Here then was one great objection removed, leaving only the trouble of over-heating which I previously found in my tests and which I now proposed to tackle in earnest, feeling confident that it only had to be understood to be overcome, seeing the general use to which this material is now being put not only on passenger cars such as I am interested in, but also on heavy lorries, omnibuses, street cars, electric underground railways, etc., in London and Paris.

I used exactly the same model of brakes as for my previous tests and was quickly able to confirm the excellence of the wearing qualities and also the silence and smoothness of the material in action, but the heat trouble was still there, the brake drums getting so excessively hot as to cause them to run right out of truth, and to be discolored all over.



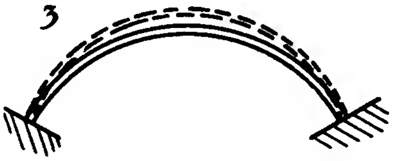


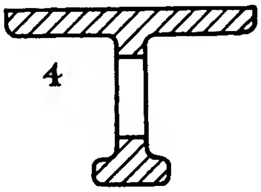
Asbestos of course is an excellent non-conductor of heat, and consequently the heat generated in the brake is concentrated on the drum, whereas in a metal-to-metal brake the heat is distributed to both the shoes and the drum and the temperature of the two members remains fairly constant, which will be seen later is an important point.

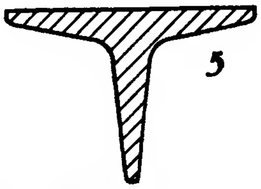
The brake used in my first experiments was of the external type shown diagrammatically in Fig. 1 and on considering the problem it will be seen at once that the asbestos insulates the drum, compelling it to retain all the heat generated, whereas with metal liners most of the heat is quickly dispatched through the shoes to the atmosphere, thus explaining why the drums should get so excessively hot when used with asbestos liners, and not otherwise.

I therefore began to realize that in order to be able to utilize asbestos liners to their full value, I must necessarily re-design my brakes accordingly, and this also explained to me the very contradictory accounts I had heard from various sources of the efficacy of these liners, and I saw that their success or otherwise depended entirely on the type of brake to which they are fitted. I therefore abandoned the external type of brake, as unsatisfactory for a heavy touring car unless a water cooled drum or other complication be introduced, and I consequently turned my attention to experimenting with an internal type of brake (See Fig. 2). In this type the heat is still, of course, concentrated on the drum, but the latter, being on the outside, has a better chance of cooling, and I was quickly able to demonstrate that in this case the drum did not get so hot, but the brake was by no means perfection.

The next trouble that demanded attention was the fact that the brake, although very efficient when first applied, gradually became less efficient if used continuously; one naturally followed this up by further pressure from the foot or hand as the case might be, until the maximum movement had been reached, whereas the brake would continue to grow less effective till it went completely off. On releasing the brake and allowing it to cool it quickly regained its former state, but would again repeat the performance if continuously applied long enough. This was exactly the reverse to the action of the other type of brake, which tended to jamb on with continuous application.







Figs. 1 and 2—Two designs of brake experimented with. Fig. 3—Distorting tendency of shoe when heated. Figs. 4 and 5—Sections of shoe used to eliminate distortion trouble.

This is only what we should expect after considering the two diagrams; in each case the drum expands due to heating up, and in Fig. 1 this has the effect of getting closer to the shoes whereas in Fig. 2 it expands away from them. If metal liners are used with either type this trouble does not accrue, as the heat being transmitted to the shoes, these expand with the drums.

The drums obviously required still further cooling, so I had some made with cooling ribs turned on the outside. These were a great improvement, considerably lengthening the amount of time the brakes could be kept on continuously. The added weight of these ribs is partially compensated for by enabling one to use thinner drums. It is signficant how the use of these cooling ribs have come into general use, coincident with the extensive adoption of asbestos liners.

I was however by no means out of the wood, there was still the same tendency for the drums to expand away from the shoes although it took longer to accomplish, and the reason this does not happen with metal liners is, as previously explained, that the shoes also expand and follow up the movement of the drum. I therefore endeavored to find a way of transmitting some of the heat to the shoes. This I did by using a large number of rivets and having the tops of these flush with the asbestos linings, which successfully lengthened the amount of time the brakes could be run continuously.

But yet another trouble arose; curing one trouble had created a second. I now discovered that after the shoes had been heated up they not only distorted, but they took a permanent set.

After carefully considering the matter I reasoned it out in the following way. Referring to Fig. 3, let us suppose the brake shoe be represented by a simple arc of metal, rigidly held at each end, which if it expanded through being heated up, one would expect to take the form shown by dotted lines, but, if in addition to being fixed at each end the drum also prevents any movement in the way indicated by the dotted lines, then the only way left is for the tendency to expand to take the form of compressing the lower face of the metal, tending to bulge out the bottom face.

If the brake is now released, cooling sets in and if the shoe cooled evenly all over it should re-assume its former shape, as permanent set under such circumstances can only be the result of unequal cooling; I therefore turned my attention to the section of the shoe which was the one most commonly used and shown in Fig. 4. It was then obvious to me that the bottom flange furthest away from the source of the heat, with its large surface and bulk of metal, would certainly cool very rapidly; mainly due, of course, to the tendency of the drilled out thin web to impede the flow of heat from the large flange. This bottom flange being under compression but the pressure at the extremities being relaxed, it therefore straightened out slightly, forcing the upper flange to form a larger radius and thus causing the trouble referred to above.

I therefore set about designing a shoe which would cool more evenly and consequently after several attempts I evolved a shoe having the section shown in Fig. 5. This I found minimized my troubles to negligible quantities, the only remaining fly in the ointment being a squeaking noise which came into existence simultaneously with the employment of a larger number of flush headed rivets in the liners.

I made a comparative test between iron, steel, copper and aluminum rivets and found the latter to give the least trouble from noise and I therefore adopted them.

I was able to satisfactorily accomplish what I set out to do, namely to produce a brake combining the qualities of silence, efficiency, absence of tendency to seize prematurely, long life, smoothness of action and reliability with prolonged application, and I feel sure my experiences should prove very useful to others desiring the same ends.

There will be some of course who will doubtless say that I went to a lot of needless trouble, their brakes being quite satisfactory although they ignore many of the points I have suggested as being necessary. To these I can only reply that the car I was working on was an exceedingly heavy and powerful touring model, and many of these points are not so essential on a light car. Or again, some people may be satisfied with a lower standard than I am, also many wait till a trouble loses them orders before they consider it important. I can only state that our old brakes gave satisfaction to most, it being only the most fastidious customers who ever complained to us about them, but now all our customers are loud in their praise of the excellence of our brakes, and I know that in a few cases they have proved a turning point which brought us the order.

In selecting a suitable fabric I have been very successful with a die-pressed, bonded asbestos for my heavy cars. The die-pressed variety will outlive the best cast-iron liners and it has a very high co-efficient of friction, being .32, which factor seems to remain almost constant under all normal conditions, being not appreciably affected by either pressure, speed or temperature. With a good fabric all three of these factors can be raised to higher values than are likely to be met with in actual practice, without destroying the material.

Aluminum Cylinders Without Iron Liners

IN our British contemporary *The Autocar*, of Jan. 8, there are two suggestions for using plain aluminum for cylinders without cast-iron liners by means of special piston design. The idea is as follows:

"The first idea consists in the use of an aluminum alloy cylinder with a thin steel piston. The piston has no rings on it, but special contractile rings are let into the cylinder walls, the piston being sufficiently long so that it does not uncover the rings either at the top or bottom of the stroke. These contractile rings are used in order to obviate the wear of the cylinder walls due to the scraping of the usual piston rings. The steel piston is long and has the advantage of reducing the specific pressure on the walls, besides omitting the weight of the rings and their containing grooves.

"The co-efficient of expansion of aluminum is considerably greater than that of steel, and therefore if an aluminum piston be used in a steel cylinder there is a tendency for the piston, in expanding at a quicker rate than the cylinder, to bind, this being avoided by the allowance of considerable piston clearance.

"If the procedure be reversed, however, as is suggested by Mr. Funck, the aluminum cylinder expands quicker than the steel piston, so that no great clearance is necessary, and the faster the engine runs and the hotter the cylinder gets the less is the tendency toward binding.

"So far as the wearing qualities are concerned, it seems reasonable to expect that the new arrangement will prove satisfactory. Aluminum pistons in cast iron or steel cylinders seem to wear quite well, and in this case the smaller surface is the aluminum piston, whereas when aluminum cylinders are used the smaller surface is of steel. There is an analogy in the white metal-lined bearing in daily use which in many cases is superior to a bearing made with a harder metal.

"The second arrangement designed by Mr. Funck consists of a plain aluminum cylinder without rings, and in this case the piston is provided with a series of grooves to act on the principle of the labyrinth packing used extensively on steam turbines. Briefly, labyrinth packing consists of a series of grooves without rings, the initial pressure being reduced step by step as the medium expands successively in the various grooves, so that before the last groove is passed atmospheric pressure obtains. In a steam turbine there is, of course, no possibility of carbon forming in the grooves, and Mr. Funck claims that there would be no fear of these grooves carbonizing up an internal combustion engine arranged according to his design, as the cooling of the engine would be very effective owing to the high heat conductivity of the aluminum alloy cylinder.

"It is thought that these aluminum cylinders should be specially suitable for air-cooled engines, with the radiator fins cast on the cylinder, and if necessary machined all over. In both cases the valve seats are shown as fixed into the cylinders separately, so that cast iron may be used."

Sterling Has Simple Chassis

New $595 Car Uses Double Expanding Brakes and Cantilever Rear Springs—Two Unit Electrical Equipment

THE Sterling, a new roadster made by the Sterling Automobile Mfg. Co., New York City, is a new entrant into the low-priced car classifications. The car is marketed under the name of Sterling-New York and although selling for $595 fully equipped, it is thoroughly up-to-date in design and incorporates many meritorious features. Among the special points of interest about the car are the Lanchester cantilever spring suspension, ample body room and low center of gravity secured by flat spring suspension and drop frame construction.

The power plant is a unit type including a four-cylinder block motor, cone clutch and three-speed gearset. The motor dimensions are 3 by 4.25 in. giving an S. A. E. rating of 14.40 hp. The piston displacement is 120.2 in. The 1¼ in. valves are in the head and are operated by rocker arms which are controlled by means of external pushrods operating from the internal camshaft. The valves are all on the left side of the motor head and the horizontal rocker arm shaft carries eight rockers, an independent one for each valve.

Carburetion is taken care of by a Zenith instrument which is carried on the right side of the motor. The intake gases flow across the top of the head of the cylinder to the valve openings which are on the opposite side of the head from the intake port. Ignition is by the Wagner battery system in which the current is furnished from the storage battery and the balance of the system is made up of the Wagner distributer mechanism and a high-tension coil. The distributer drive is from the forward end of the timing gears which provides an accessible location. The high-tension coil is mounted on the side of the motor, giving very short connections between the breaker distributer mechanism and the coil.

Splash lubrication is employed, the oil being carried in the bottom half of the crankcase.

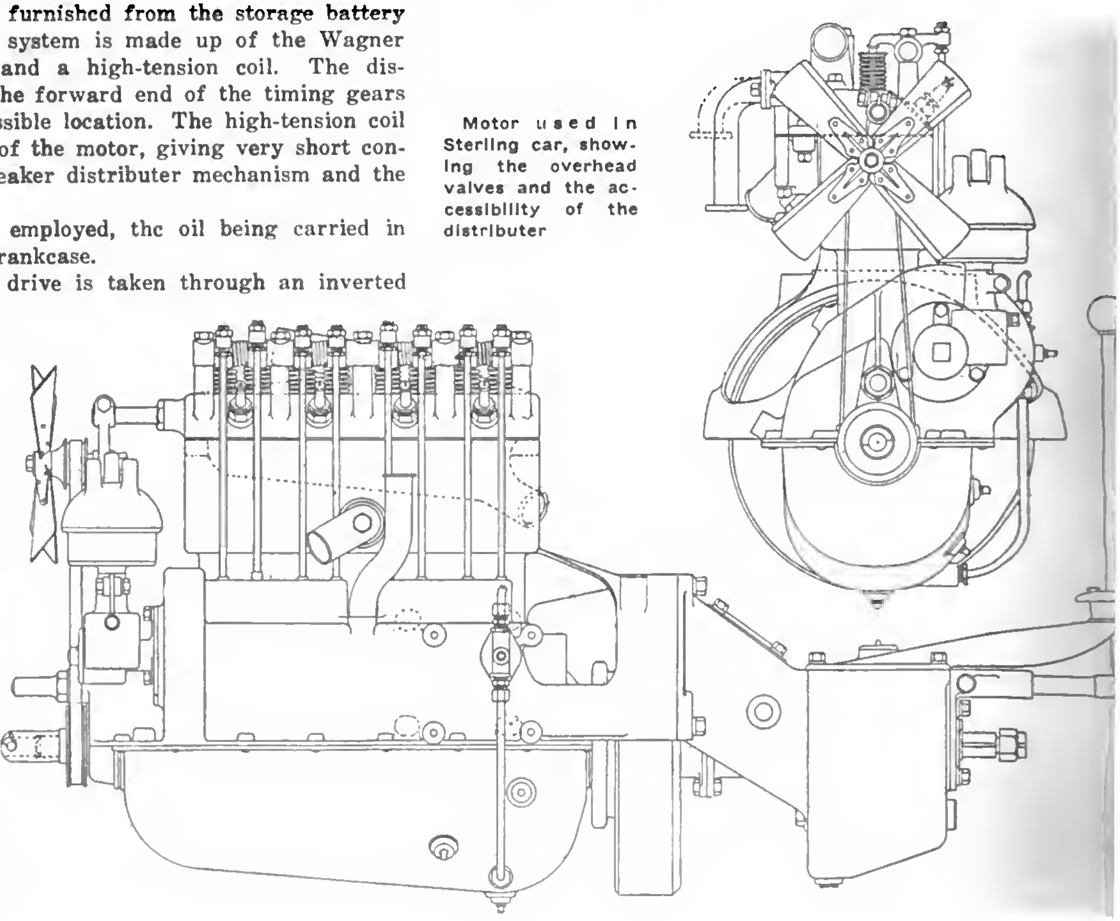
From the motor, the drive is taken through an inverted leather-faced cone clutch to the three-speed sliding selective gearset. The housing of the flywheel and gearset has been kept light by reducing the amount of metal necessary here to a minimum. The assembly is also compact, the distance between bearings is short providing rigid shaft construction. The gearshifter lever and the hand brake lever are mounted on an extension of the gearbox cover plate. This is done to bring the position of the levers to a convenient location for the driver. At the same time, the rigidity of a cover plate mounting is maintained. The entire power plant is self-contained with very few external parts outside of the valve mechanism. Since the motor is water cooled, there is no water pump and the neat block casting and self-contained working parts combine to render the assembly quite clean.

Lighting and starting are by the electric Auto-Lite system which is made up in two units, the generator is driven by silent chain and the starting motor has the Bendix gear attachment for meshing with the flywheel.

Bearing Provision Ample

Anti-friction bearings are used throughout the entire power transmission mechanism, the gearset being mounted on ball bearings and employs chrome-nickel steel gears. The semi-floating rear axle is also made up of chrome-nickel steel units carried on ball and roller bearings. The parts made of chrome-nickel steel are the bevel gears, pinion and driveshafts.

Two sets of brakes are on the rear wheels. These are lined with Raybestos. The wheels are wood-artillery type made from hickory and given a natural wood finish. They are equipped with quick-demountable rims and the standard equipment includes an extra rim. The standard tires are



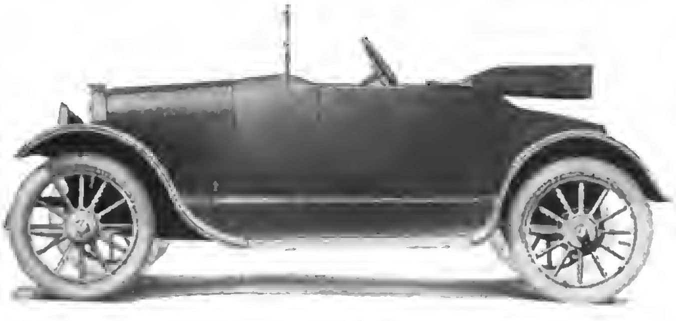
Motor used in Sterling car, showing the overhead valves and the accessibility of the distributer

30 by 3½ Swineharts. The wheelbase dimension is 102 in.

In exterior appearance and equipment, the car is a straight streamline design with no perceptible break in the body line between the cowl and the bonnet. The fenders are crowned and are made of heavy-gage steel with full skirts and dust shield. The running boards are covered with linoleum.

Equipment Is Complete

The price mentioned includes full equipment which is specifically mentioned as a full set of lamps, the headlights being 10½ in. adjustable focused type with Mazda bulbs, electric tail light with license bracket, rain vision ventilating windshield, mohair one-man top, extra rim, tire irons, tools and tire pump. The standard finish is blue, black or gray with either natural or painted wheels.



The Sterling Roadster

Economy of performance has been made a feature of the design. The car is light in weight and the construction is unified so as to maintain the number of parts at a minimum. The seating space has not been slighted and in accordance with the latest dictates in body design, the doors are large and have concealed joint lines and hinges.

Dust-proof Envelope

The top is held in a dust-proof envelope which is so arranged as to provide a firm support for the top and at the same time to conform to the lines of the body without sagging. It does not interfere with the rear deck, beneath which baggage may be carried if desired.

Low price attained by efficiency of design and by simplicity is the keynote and each detail from the ground up has been worked out to go suitably with the rest.

George Automatic Roller Bearing

Compensates for Variations in Roller Diameters

A ROLLER bearing which has been described as automatic has been placed on the market by the George Automatic Roller Bearing Co., Cincinnati, Ohio. This bearing was first shown the automobile engineers on the last summer's excursion of the Society of Automobile Engineers on the Great Lakes. It may be described roughly as a roller bearing in which the rollers are held in suspension on balls. It combines the functions of a radial and thrust bearing and has as an important feature of merit that it automatically compensates for commercial variations in actual roller diameter.

Balls Adjust Rollers

A general view of the bearing which will bring out the fundamental principles of its construction is shown in Fig. 1. By the construction of this bearing the rollers are separated by two rows of balls which, while decreasing frictional resistance, produce an automatic adjustment for the rollers. Furthermore the construction is such that concentricity is maintained without compelling expensively close limits in machining. An ingenious method of mounting and dismounting the bearing has been provided and the entire assembly can be taken apart for inspection and cleaning without the use of tools or distortion of the parts.

Briefly, the bearing is conical; this being so the rollers are tapered to compensate for the conical race and the tapered rollers have lateral freedom controlled by the contact of the balls at *A* Fig. 1, on the conical ends of the rolls *B*. When the bearings are mounted and tightened in place there is a certain wedging action on the rollers, but as soon as the bearing has made a half turn the large rollers are forced to creep owing to the pressure upon them, thus forcing the balls in contact further apart. This pressure is equalized all around the outer and inner rings because the balls are

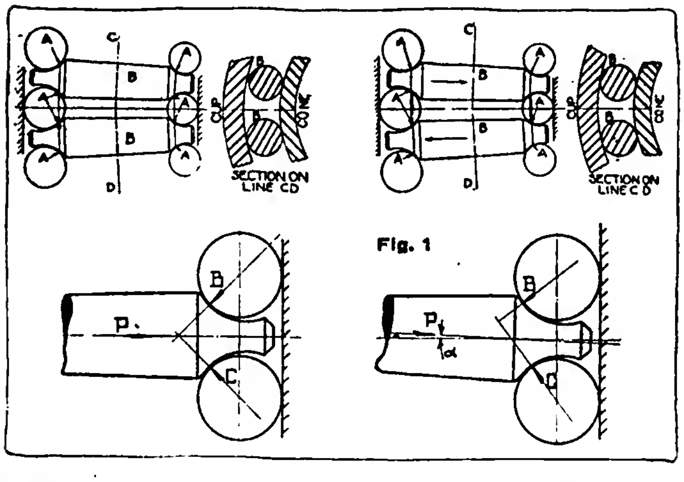


Fig. 1

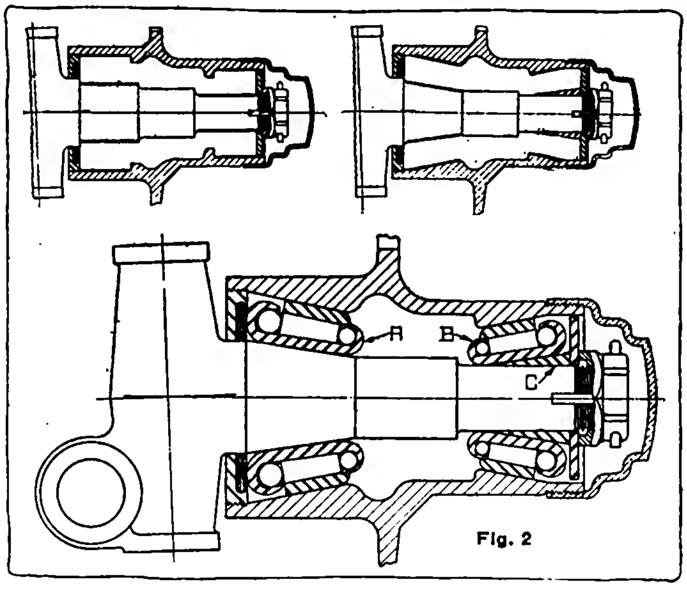

Fig. 2

Diagrams and assembly sections showing the construction of the George automatic roller bearing and the action of the balls and rollers under the stresses due to load. The compensating action of the balls and rollers on the conical race is the novel feature. The upper diagram on the right shows in comparative form the amount of accurate machining required on the hub with the George and with the parallel type of bearing pressed into their proper running positions automatically. The large and small rollers thus automatically take their places, being forced either forward or backward until the same working diameter between the cap and cone is produced all around the bearing.

Suppose one of the rollers is a trifle thick and another a trifle thin, then the thick one will receive more than its share of the load, and directly the bearing begins to turn it will slide outwards till it takes no more than the load on the others. This outward sliding, however, puts pressure on the outer ring of balls and lets it off the inner ring, so the effect of a thick roller sliding outwards is to press any small roller inwards, so effecting compensation.

All roller bearings need a separating medium for the rollers. In this particular bearing the balls at the inner and outer ends of the rollers are used as separators. This design provides rolling contact between the balls and rollers thus eliminating the frictional resistance which would come from a sliding action. Also, the conical ends of the rollers acting in conjunction with the balls form a true concentric rolling action and overcome tendency to skew out of the true rolling axis.

Referring to the lower part of Fig. 1 if there is *P* pounds end thrust on each roller there will be a reaction through the balls along the normal lines *B* and *C*. Owing to the shape of the end of the roller the angle made by *P B* must be the same as the angle made by *P C*. consequently the forces *B* and *C* are of the same magnitude and the axis of rotation must remain true. To the right of Fig. 1 at the lower corner is shown the alternative condition where the angles are not equal. This would provide an unbalanced force, with the result that the bearing would tend to slide away from its true rotative axis.

Simplifies Machine Work

One of the claims for the bearing is that in mounting, it is unnecessary to have great accuracy in machining. Both the inside and outside surfaces of the bearing are taper and hence concentricity is obtained by tightening the bearing in position.

At the same time any small variation in diameter of the housing or seat in mounting is taken up by a very slight lateral movement of the whole bearing. Fig. 2 shows a typical installation of a front hub fitted for George automatic roller bearings. As will be noted, the tapered surfaces render unimportant close limits in machining for the bearing mounting.

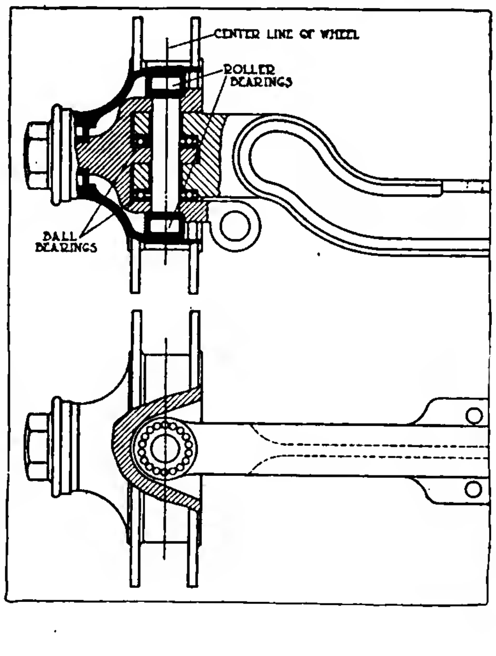
In the typical George mounting shown, the bearing *A* does not touch any part of the spindle until it rests on its tapered seat. The hub is then mounted by moving it laterally until it rests upon its tapered seat and bearing *B* is then put into position and it in turn must come to rest on its tapered seat. The split tapered collar *C* is then slipped over the spindle and that again must rest on its tapered seat after which, the splined washer, lock adjusting nut and cotter pin are put into position in the usual manner. The entire assembly is then concentric with the axis of rotation of the wheel and this has been accomplished without the use of special tools or any force.

In dissassembling the bearing the first ball is dropped out of a little opening in the periphery of the larger race. After this is removed another ball can be dropped out and then the rollers can be pulled out by canting them sideways and lifting them from place. The other balls then drop out. The reassembling work is easily accomplished by simply reversing the procedure. There is no danger of the bearings falling apart when packed in position as it requires manual separation of the rollers to allow the first ball to drop out of the opening.

The mounting illustrated, of course, needs a special hub or housing to take the George bearing, but the manufacturers are now prepared to supply bearings with an integral outside part that will enable them to be interchanged with other bearings of the long series type.

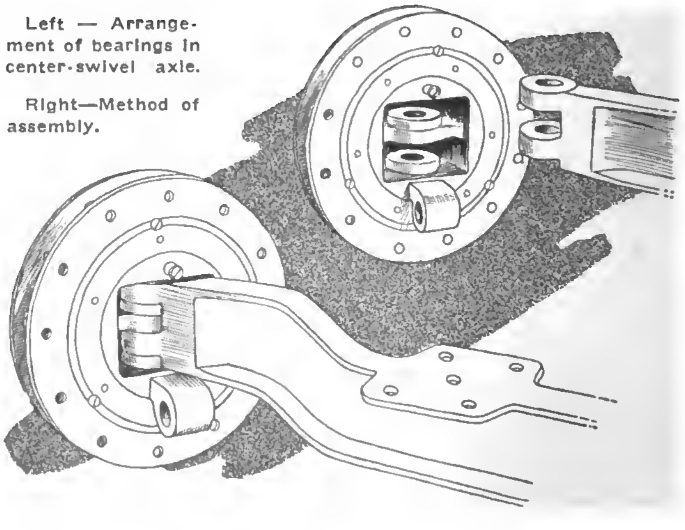
A Design of Swivel Giving Centrally Pivoted Steering

With reference to a recent article in THE AUTOMOBILE on the layout of steering gear Elmer E. McIntyre, ball and roller bearing manufacturer, Pittsburgh, Pa., calls attention to his center swivel front axle, which provides the ideal front wheel mounting without clumsy parts. The illustrations are completely self-explanatory except for the large diameter roller bearing which surrounds the swivel. The weight is taken on two ball thrust races, and the roller wheel bearing is located centrally in the plane of the wheel which is mounted vertically instead of being dished. No road shock barring a glancing blow can deflect the steering.



A feature of the device which is uncommon among centrally placed swivels is that it does not need an ugly or cumbersome wheel hub to accommodate it, and it has the further advantage of being reasonably inexpensive to make. It would be difficult to imagine any sort of axle end easier to forge than this.

Having due regard to its undoubted advantages, it would be interesting to know how many American manufacturers have actually tried out a center pivot axle. In Europe the experiments have been few and far between.



Left — Arrangement of bearings in center-swivel axle.

Right—Method of assembly.

The Rostrum

Minervas In Isle of Man Races

EDITOR THE AUTOMOBILE:—How did the three Minerva-Knights perform in the Isle of Man races a year ago? How did these cars differ from the stock models?

2—Does not an Argyll single sleeve valve motor hold some records on Brooklands track? What are the differences from a stock car of this make?

3—Please publish a horsepower chart of the 1913 Stearns-Knight.

Mesa, Ariz. H. G. A.

—The three Minerva-Knight cars performed excellently in the Isle of Man races. They did remarkably well considering they were the first racing cars made by the Minerva company. They suffered extensively from broken connecting-rods. The motor did not in the least resemble a stock Knight motor as it had large exhaust ports at the bottom of the cylinder, the opening of which was also controlled by the sleeves. At the top of the cylinder the intake and exhaust ports were much larger than usual.

2—An Argyll sleeve motor in 1914 took the world's record for 12 to 14 hr. continuous running on the Brooklands track. This car was a stock car with a single-seated body slightly different gear ratio and special carbureter. Please note the Argyll is no longer manufactured and the single sleeve valve had nothing to do with Knight, very much on the contrary.

3—A horsepower curve of the Stearns-Knight six-cylinder 1913 motor is published in Fig. 1.

Circuit Breaker Cam is Worn

Editor THE AUTOMOBILE:—I have a Great Western four-cylinder car and for some time it has been missing on No. 1 and No. 4 cylinders and I am unable to remedy this. The plugs are all right and the compression is good. I have put new platinum points in the magneto breaker, which is a Remy, have cleaned the carbon from the cylinders, adjusted and readjusted the spark plug points. Have tried new plugs, changed them from 2 and 3 to 1 and 4; have adjusted the carbureter, but still, numbers 1 and 4 miss. Some times they miss and then again they do not. This occurs at both low and high speeds, with and without load. I have also ground the valves. Please advise me just what the trouble can be in this case.

Bastrop, La. A. G. McB.

—The circuit breaker cam in the magneto is probably worn so that the circuits are not broken on cylinders No. 1 and 4, or the distributer gaps for these cylinders might be too wide. Leaky valves or manifold connections might also account for the missing cylinders.

Repair Business Should Be Success

Editor THE AUTOMOBILE:—Is there much profit to be made repairing automobiles?

2—What salary does the average repairman get?

3—Can one become an expert in ten weeks at an automobile school?

4—Which is the quickest and most thorough way to learn the business, in a repair shop or in a school?

Honea Path, S. C. B. S. M.

—This seems to be largely dependent upon the methods of doing business, as there are a large number of successful concerns and also a large number who do not survive. Putting the matter on a broad basis, however, there is no reason why a properly conducted automobile repair business in a proper locality should not prosper.

2—This varies through quite a range but probably $18 a week would be an average.

3—No.

4—A combination of both makes the ideal repairman. He should have a knowledge of the theory as well as the practice.

Installing an Ammeter on Chalmers

Editor THE AUTOMOBILE:—Kindly send me a sketch showing how to install a charging and re-charging ammeter on model 24· Chalmers; also let me know the highest reading that this ammeter will require?

New York City. E. O. H. C.

—The method of procedure in both cases is identical and the ammeter should be cut in off the battery lead as shown in the diagram Fig. 2. The reading of the ammeter should show on charge from 0 to 25 and on discharge 0 to 150.

12-Volt Generator on 6-Volt Battery

Editor THE AUTOMOBILE:—Approximately how much and what size of fine wire would be used in making a cutout relay to work on a 6-volt generator?

2—How can a 12-volt generator be used with a 6-volt storage battery and 6-volt lamps?

3—When pistons are found to fit too loosely in cylinders and cause piston slap, can anything be done with them except fit larger pistons? Have heard they could be enlarged by heating. What is your opinion?

Manitoba, Canada. J. S. C.

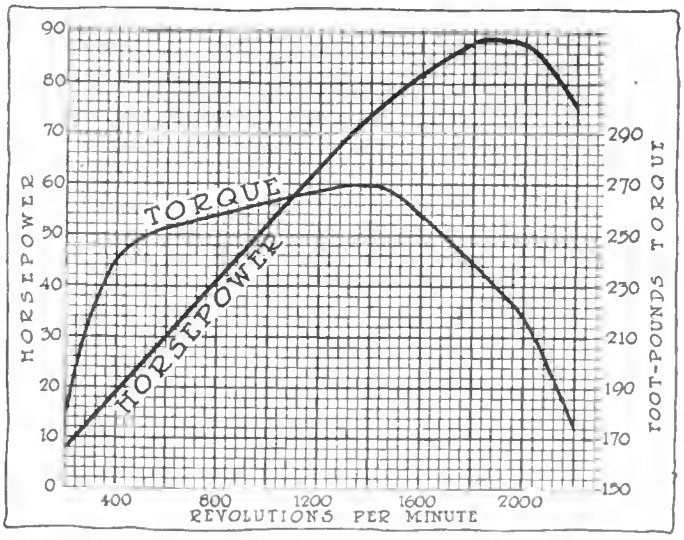


Fig. 1—Horsepower and torque curves of the Stearns-Knight six-cylinder motor of 1913

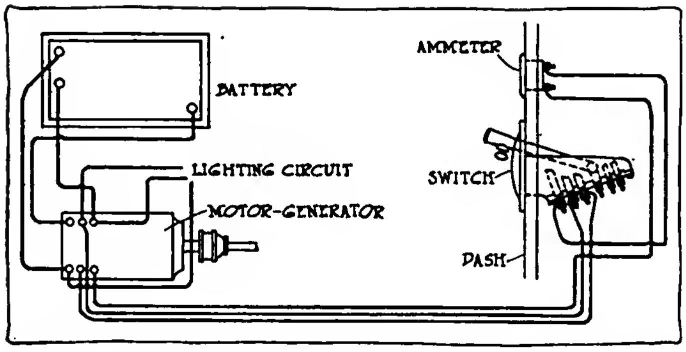

Fig. 2—Wiring diagram showing connections of ammeter on model 24 Chalmers

—The amount of wire and size will vary with the design of the cutout, but it will approximate in general the ordinary bell buzzer winding designed for that voltage.

2—It is a rather difficult proposition to use a 12-volt generator with a 6-volt battery. A 12-volt generator, if its fields are connected in series, can sometimes be changed to a 6-volt by connecting the field in parallel. The generator can also be made to develop 6 volts by cutting the speed in two. When this is done the generator, battery and lamp will work together, although the capacity of the generator will be limited to a considerable extent.

3—The only safe method is to fit larger pistons.

Finding Horsepower by Formula

Editor THE AUTOMOBILE:—Will you please tell me how to find the horsepower of automobiles?

2—What is the horsepower of a car that is 3¼ by 5 in.?

Jamestown, N. Y. K. B.

—Multiply the bore of the motor by itself, then by the number of cylinders and divide by 2½.

Many Factors Determine Car Speed

Editor THE AUTOMOBILE:—Please give me some information regarding two Overland cars. One is a 1914 model 79 F and the other is a 1915 model 81. The 1914 has a 35 hp. motor and 4 to 1 gear ratio and the 1915 a 30 hp. motor with 4 to 1 ratio. Please give the actual speed of these two motors in miles per hour; that is when the momentum of the car is not pushing the engine. Both cars use 33 by 4 tires.

Anna, Ohio. O. E. H.

—It is impossible to give a definite figure in speed in miles per hour for these cars, as they vary considerably with the condition of the motor, the tightness of the bearings, the atmospheric conditions, adjustment of the carbureter and many other factors. In fact, two cars taken out of stock will not make the same speed due to variations in adjustments, etc. It is impossible to give more than an approximate speed, therefore, and in each case this is about 50 m.p.h.

Using an Alcohol Hydrometer

Editor THE AUTOMOBILE:—Kindly advise me how to use an alcohol hydrometer. I wish to test the strength of the alcohol solution in the radiator of my car so I can determine whether I have a safe margin to allow for the various temperatures. I have purchased an hydrometer which is marked as follows: "U. S. C. H. Hydrometer for Spirits with Tralles Scale for Alcohol temperature 60 deg. Fahr."

New York City. W. S. J.

—The way to use a hydrometer in order to test freezing solution is to first make the mixture in your radiator that you desire to use. A reading on the hydrometer is then taken and as the alcohol evaporates readings are taken on the hydrometer and sufficient alcohol added to bring back the reading to the original.

Valve Spring Pressure of Racers

Editor THE AUTOMOBILE:—What is the relation of valve diameter and width of valve seat to valve spring pressure?

2—What are the valve spring pressures of the Chalmers 6-40, Mercer 22-70, Duesenberg motors, Peugeot, Mercedes or other racing cars with overhead valves and camshaft?

3—Where can I obtain some two- or three-ply wood veneer similar to that used in building bodies before metal came into use?

4—How is skin friction, or the friction caused by a body moving swiftly through the air, computed?

5—In a magazine which is no longer published, I read an article in which the author, wishing to show the importance of wind resistance, gave the following example and law, "The wind resistance of a moving body increases as the cube of its speed." He then cited that the wind resistance of a body moving 60 m.p.h. would be twenty-seven times as great as at 20 m.p.h. He obtained this by dividing 60 by 20 and cubing the resulting quotient. This computation of wind resistance and the curve of wind resistance published in THE AUTOMOBILE for Sept. 2, on page 428 do not quite agree. Will you please tell me which is correct?

Akron, Ohio. R. T. O'B.

—The relation between valve diameter to valve spring tension is simply empirical. There is no definite rule which designers follow in this respect. In general, it may be said that the speed of the motor affects the stiffness of the spring more than the points you mention as at high speeds it is necessary to have a spring which will close the valve sufficiently rapidly to prevent the cam from running away from the follower. It must be remembered that the spring acts with the gas pressure against the cam action so that in lifting the valve, the cam must lift the load of the spring plus the load due to the area of the valve upon the pressure is acting. In closing, the gas pressure is immaterial as at that time it has generally reached close to atmospheric.

2—Some of the concerns which you mention object to the publication of details such as the valve spring pressure. On the Duesenberg motor, for the eight-valve type an 80-lb. spring is used on the intake and a 90 on the exhaust. For the sixteen-valve Duesenberg the intake valve spring is 60 lb. and the exhaust 70. The eight valves are 2 3/16 in. diameter and the sixteen valves are 1 13/16 for intake and 1⅞ for exhaust. Owing to the heavier valve on the eight-valve type it will be noted that slightly heavier springs are used. On the Chalmers 6-40 model 32 the valve spring pressure is 49 lb.

3—The nearest concern to you of which we have record is the Empire Panel & Veneer Co., 940 Seneca St., Buffalo, N. Y.

4—This subject takes up more space than is available here but if you will secure any standard work treating on Froude's laws of friction you will find therein the information you desire.

5—The wind resistance curve published in THE AUTOMOBILE for Sept. 2 is based on the well-recognized Smeaton's table, which is largely used in building calculations. There are various other formulas which give wind resistance results which vary from Smeaton's calculations, but the latter are generally accepted.

Use Dull Paint Under Varnish

Editor THE AUTOMOBILE:—I have a Ford roadster and want to repaint it. I want the running gear a bright red, the fenders black and the body blue. In painting it would it be advisable to use a paint with a glossy finish over the old paint or to use a dull finish paint and varnish it afterwards?

Laceyville, Pa. B. W. F.

—It would be better to use a dull colored paint rubbed down and finished with varnish. You can obtain the materials required at any paint store.

Wheel Warmers Consume Little Current

Editor THE AUTOMOBILE:—I am contemplating the use of electrically operated hand warmers on the steering wheel of my Dodge car. Do devices of this sort consume a very great amount of current? Inasmuch as I keep my car in an unheated garage and it requires considerable spinning to start the motor on cold mornings, I do not want to run any risk of having my battery fail me. What can you advise?

Bedford, N. Y. G. A.

—These devices consume very little current and should not prove to be a serious drain on your battery. Entire steering wheels embodying this feature may also be purchased very reasonably.

Franklin's Thermal Efficiency is High

Editor THE AUTOMOBILE:—What is the average operating temperature of the Franklin air-cooled motor? What advantages do the manufacturers claim for it and what is the effect of the higher temperature on the thermal efficiency?

Lawrence, Kan. B. B.

—The average operating temperature of the Franklin car is a little higher than that of a water-cooled car. The possibilities of going considerably higher can be seen by a study of the cooling system.

Just as it is difficult to say what is the average temperature of water-cooled cars, so it is difficult to say what it is with the Franklin. The maximum temperature at which a water-cooled motor can operate is naturally the boiling point of water, or normally 212 deg. The maximum temperature used in this motor is 350 deg.

The oil recommended by the Franklin company has a flash point of 435 deg. and a fire of 490 deg. Naturally the higher the temperature, and providing the lubrication is satisfactory, the greater the thermal efficiency.

Information on the 1914 Cadillac

Editor THE AUTOMOBILE:—What is the actual horsepower of a 1914 Cadillac?

2—What is the bore and stroke of this car?

3—As I understand, this car has a double axle and has four speeds forward. What is the maximum speed that this car can make on third speed and what is the maximum speed it will make on its high-speed axle or its fourth speed?

4—What does this car weigh?

5—When the pressure of this car is pumped to 1½ lb., it drops to about ½ lb. pressure in about 6 min. What is the cause of this?

Brooklyn, N. Y. B. U.

—The actual horsepower of this motor is between 40 and 50.

2—The bore and stroke are 4½ and 5¾, respectively.

3—The rear axle of the 1914 Cadillac is fitted with two direct drives. The transmission was supplied with three speeds. It was intended that the transmission and axle be operated in the folowing manner:

Start the car on low gear, shift into second, then into high in the transmission. Then when the speed of the car increases to 19 m.p.h. or higher, shift the axle into the high direct, providing, of course, that the car is being driven at the time over fairly good roads and in reasonably level country.

4—The shipping weight of the five-passenger 1914 Cadillac was 4095 lb.

5—If the air pressure drops from 1½ lb. to 1 lb. when the engine is running it indicates either that the pump is not properly lubricated or that the pump cylinders or pistons are worn somewhat.

Single Electric Lighting for Ford

Editor THE AUTOMOBILE:—Please tell me how I may wire a Ford car for electric lights and have two independent systems; the storage battery to be wired in parallel and the magneto in either series or parallel.

It must have a foolproof switch so that only one system can be turned on at a time.

Modesto, Ill. K. L. N.

—It is not practicable to attempt to operate the headlights by two different systems, and if you use a storage battery it will be necessary to disconnect the present lighting wires to the magneto. The lights cannot be operated by both the storage battery and the magneto at the same time with satisfactory results. By attempting to do so you would undoubtedly demagnetize your magnets and cause ignition trouble. A storage battery cannot be recharged by the Ford magneto.

Wants Information on 1910 Thomas

Editor THE AUTOMOBILE:—Will you kindly answer the following questions pertaining to a 1910 model M Thomas car?

1—What is the cause of poor compression in two of the cylinders after the valves are properly ground in?

2—Would you advise putting in patent piston rings?

3—Is there any arrangement to advance the timing of the valves without touching the timing gears?

4—How do you time an engine of this make?

5—What are the functions of the ⅝-in. set screw and lock nut set between the pairs of tappet bushings?

6—What causes a grinding noise in the transmission on level ground and when going up hill the noise ceases?

7—What are the adjustments on the Stromberg carbureter on this model?

8—Could you tell me of any 1914 body which I could put on this car without many alterations?

Lynn, Mass. C. C. S.

—This is probably caused by the cylinders being worn out of true, or perhaps a scored cylinder or poor rings.

2—Unless the cylinders are round new rings will not do any good. If they have been worn oval it will be necessary to have them reground. If oversize pistons are fitted any reliable ring will do.

3—No, except by changing the adjustment of the push rods.

4—The two important things in timing the motor are the closing of the exhaust and the opening of the intake. On this motor the exhaust valve should start to close on the exhaust stroke 1/32 in. over center and the intake valve should start to open 1/16 in. in all. If this is carefully done and the push rods are given 6/1000 to 7/1000 in. clearance on the exhaust side and 4/1000 to 5/1000 on the intake side the timing will be correct.

5—The set screw and lock nut between the cylinders are to hold the camshaft bearings in place.

6—It is possible that the trouble is in the trunnion or it may be in the differential. This would have to be determined by a mechanic.

7—The adjustments on the Stromberg carbureter are made through the adjusting screw on the air spring at the bottom of the air intake for low speed and the adjusting nut on the top of the intake for high speed. It is also necessary to see that all joints are right and the proper spray nozzles are used.

8—I would be almost impossible to fit a 1914 body.

The FORVM

ADVANTAGES OF OVER-SIZE TIRES WITH LOW AIR PRESSURES IN GIVING FREEDOM FROM BLOWOUTS—HISTORY OF ALUMINUM PISTON

First Aluminum Alloy Pistons Made in France

LONDON, ENG.—Editor THE AUTOMOBILE:—With reference to the letter of Joseph Leopold regarding aluminum alloy pistons in your issue for Nov. 25, we know nothing about American aluminum alloy pistons as we have not had the good fortune to be able to test them, but we have no doubt that they are satisfactory.

Our reason really for writing to you is in the interests of historical accuracy, since we see that Mr. Leopold claims that a German alloy was used almost exclusively for aluminum alloy piston construction in Europe. To be quite correct, this is in no way the case since the first aluminum alloy pistons ever manufactured and fitted to motor car engines were produced by Messrs. Maxime Corbin et Cie. in France eight years ago. These pistons have been fitted as standard by Messrs. Chenard et Walcker for the last five years and by Messrs. Doriot, Flandrin & Parant for the last two years. We believe that neither of these firms has ever had to replace an aluminum piston during this time and we know that large numbers of Chenard et Walcker cars are in use in different parts of the world without their owners being aware that they are fitted with aluminum pistons.

The article by Mr. Sherbondy struck us as being very close to the truth and we do not see why Mr. Leopold should state that the European aluminum pistons were only worthy of superficial consideration, unless, of course, he is referring to the German ones, since he admits that his company has been able to improve on these.

This letter is simply written with a view to informing your readers of the situation as we could not hope to sell European pistons in America and have nothing to gain in this connection.—THE ALUMINUM PISTON CO.

Oversize Tire Advantages

By Charles E. Manierre

EDITOR THE AUTOMOBILE:—Up to date the tire manufacturers seem to have made no special effort to set forth the virtues of the over-size tires. It therefore seems proper occasionally to refer to the subject in your paper and to emphasize the fact that such tires when used should not be inflated to a pressure equal to the regular sized tire and much less than the pressure sometimes stamped upon the casing.

Referring to your issue of Nov. 25 last, at page 956, we are reminded that the standard sizes recommended by the S. A. E. are limited to the following: 30 by 3, 30 and 32 by 3½, 32 and 34 by 4, 34 and 36 by 4½, 36 by 5, 38 by 5½. That is to say, only nine regular sizes for the use of manufacturers, all of them an even number of inches in diameter, and for each of these regular sizes an over-size 1 in. larger in diameter by ½ in. larger in cross section.

It is to be hoped that automobile makers will keep to the even sizes so that individuals may always have the option of increasing their insurance against blowouts by purchasing the over-size tires.

Your issue of Oct. 22, 1914, contained an interesting letter from Mr. Parsons of the Palmer Tire Ltd., including a table showing the diminishing pressure in pounds per square inch for any given load for each ½-in. increase in the size of the tire. For example: a load which requires a 60-lb. pressure on a 3½-in. tire requires only a 48-lb. pressure on a 4-in. tire, or 42 lb. for 5 in. Also a heavier load, requiring 80 lb. for 3½-in. requires 62 for 4-in., 56 for 5 in., 40 only for 6 in. This diminishing inflation is in accordance with common sense.

So far as the cost is concerned, a set of six regular sized tires costs about the same as five over-size tires. But the five over-size tires will outlast the six regular tires, and at the same time give much less trouble, together with more comfort in driving. I have seen from time to time a number of letters warmly praising the use of the over-size and none whatever discouraging such use.

My own experience in three years' driving, using the over-size (35 by 4½), gives but a total of three inner tube punctures on the road, and I think that each of these was more or less my own fault. Prior to the change from the regular tires the punctures had been quite a common incident.

For a time after putting on the over-size I faithfully inflated them to the pressure of 90 lb. stamped upon the casings, and hard riding was the immediate result. Later on the pressure not infrequently fell as low as 35 lb., both front and rear, and I have no idea how much driving I did on those under-inflated tires. I believe that it was a great many miles at or near that pressure. The fact that they were under-inflated did not appear when the car was standing without passengers. It would seem that instead of 90 lb., 60 lb. for the front wheels and 70 for the rear wheels is the outside that would be necessary. By this I do not mean that those are the pressures that should always be found in the casings, but the pressures to which they should be inflated with the expectation that they will run down somewhat below those figures in the course of driving. This over-size and the pressures mentioned should take care of a 3000-lb. car with five passengers.

May I suggest that in addition to increased comfort there is more satisfaction in driving with tires which scarcely ever bring one to a halt by the wayside and in not having (even with two extra casings inflated and ready for substitution) the lurking fear that two blow-outs may not be the sum total for the day. One extra over-size casing is an almost absolute insurance against any tire repairing at inconvenient points on the highway.

I confidently urge upon the prospective purchasers of tires the favorable consideration of the over-size question, particularly as the regular size tubes can be used in the over-size casings so that the expense of the change is only for the actual casings themselves.

The History of the American Automobile Industry—14

Activity in France Began Mainly After 1870—Bollee, De Dion and Serpollet Amongst the Pioneers—Internal Combustion Engine Soon Replaced Steam

By David Beecroft

IN 1861 the government of Britain passed a uniform tolls act and added to the difficulties of the situation by regulating the engine sizes, the weight on each wheel and limiting the speed to 10 miles in the country and 5 miles per hour in the cities. Also requiring at least two men with each vehicle. Seeing that the power vehicle was not wholly killed by such treatment an amendment was passed in 1865 limiting the speeds to 4 and 2 miles respectively and requiring an attendant sixty yards ahead with a red flag to warn riders and drivers. Naturally the business could not continue much less grow and the hardy pioneers were whipped, not by the problem, but by the vested interests speaking through the law makers.

France Starts in 1870

In France very little was done prior to about 1870. The firm of Lotz, of Nantes, were traction engine builders and their engines were frequently used to haul omnibuses, but they built a sort of steam carriage in 1865. With civil war and an immense new country to develop in America, with foolish restrictive laws in England, France became the logical development ground for the yet-to-be vehicle. The velocipede had gained considerable favor both in Europe and America and while largely out of fashion in America had left its imprint on British and French mechanical minds.

The next 20 years was to impress three names in particular on the minds of American students, viz., Bollee, De Dion-Bouton and Serpollet. Amidee Bollee seems to have begun his work as early as 1872 and built a number of steam automobiles, one of which was exhibited at the Paris exposition in 1878. This vehicle, or a mate to it, was also shown in Berlin and Vienna and driven over much of central Europe. It had the engine inclosed at the front of the vehicle, much like modern gasoline cars. It was the pioneer in this design.

The boiler was vertical and at the rear with coal bins each side, and the vehicle could travel 18 to 22 m.p.h., using for that distance 8½ to 11 lb. of coke. In many ways it marked a very considerable advance from the cruder and heavier structures that preceded it, if we except the several light steam buggies that had been used in America.

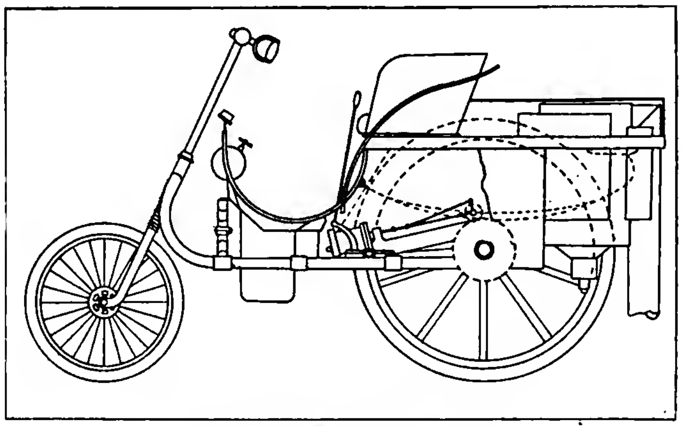
Another small vehicle turned out by Bollee about 1885 had a wheelbase of 75 in. and a gage of 33 in. Its frame was of steel, as were the wheels of which the fronts were 30 in. in diameter and the rears 39. The boiler was located in front with a water capacity of 7½ gal. The total weight was but 1430 lb. and the speed from 21 to 24 m.p.h. maximum.

De Dion Starts with Steam

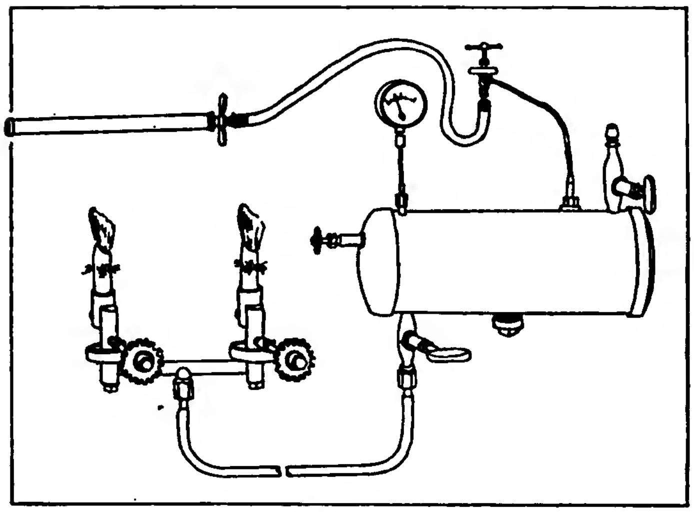
Count de Dion and his partners in manufacturing took up the automobile problem in 1883, and began with that best known motor, the steam engine. With them as with all others, the biggest obstacle to producing a light vehicle was found in the boiler and it was not till 1884 that they appeared with a tandem tricycle having the boiler and engine in the place of the second seat. This attempt was quite light, its motor had about 1 hp. and could run up to 18 m.p.h. on perfect roads.

In 1885 they brought out another tricycle in which the steam generator was carried between the steering wheels and the seat over the rear wheel, which was driven by a tandem compound steam engine directly connected. This machine was driven by Bouton as fast as one kilometer per minute.

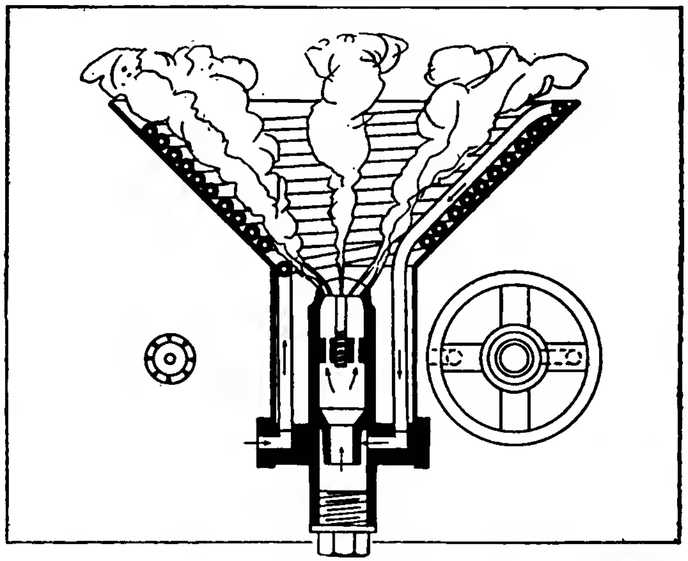
In the next 8 years they made a number more of these vehicles of different types, including a small carriage carrying its entire mechanism at the front but with the connecting-rods of the two tandem compound engines extending to and driving the rear wheels. The seat was wide enough for four people, and the weight about 1300 lb.



One of the first Serpollet steam cars



The principal parts of the Longuemare burner for a flash boiler of the Serpollet type, including fuel tank and air pressure pump to spray the gasoline.



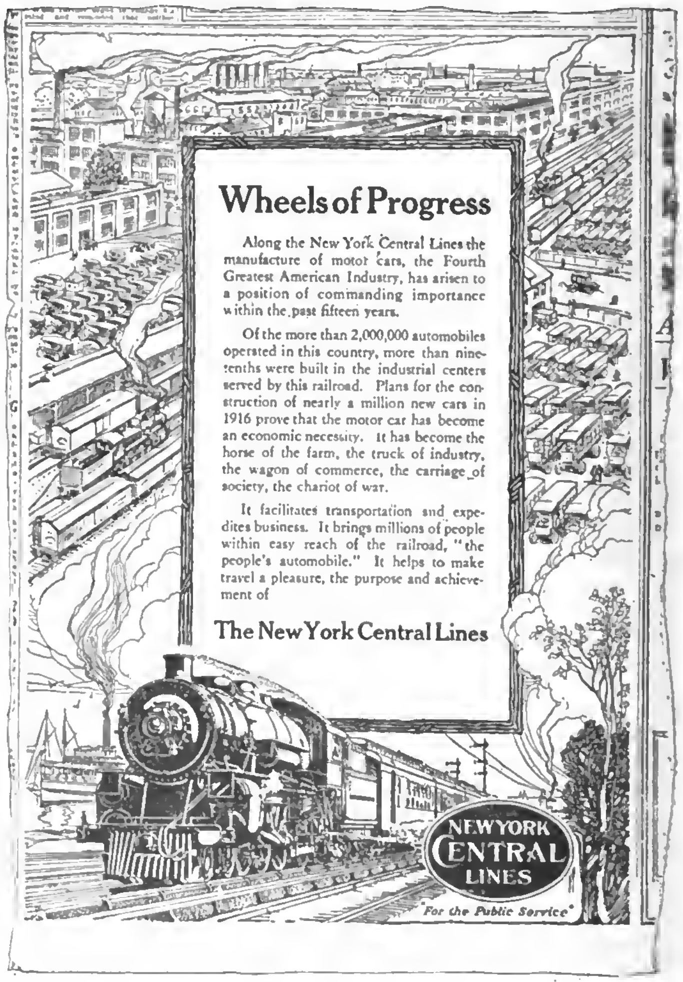
Details, in a diagrammatic form, of a Longuemare burner intended to burn kerosene

They next turned their attention toward steam tractors and won the Paris-Rouen contest of 189 with one of these. Its front wheels were rub tired, but the rears were shod with iron. It weighed 3500 lb. empty, and 5000 lb. loaded and charged with water for 20 miles, and fuel for 60. Its construction embodied a form of full floating rear axle.

Serpollet's Flash Generator

Both Bollee and De Dion soon took up the gas engine and so the best known French advocate of the steam vehicle is Serpollet. Confronted as was De Dion and every other builder for road use, with the fact that the demands for steam varied almost constantly and over much range he took up the problem of the steam generator and produced one having flattened tubes which exposed a very large surface to a small amount of water. These flat tubes opened up and so defeated his intent, which objection he met by making them curved in cross-section. He also used very thick walls and attempted to store the heat in these walls so that when a sudden demand for steam came the walls themselves would largely meet it. His first vehicle, built about 1886, was a very crude tricycle design with boiler at the rear. His next tricycle had rubber tires and was a noticeable improvement. The next year, 1889, he built a seven-passenger tricycle weighing 2500 lb. empty, and about 4000 lb. loaded. The rear wheels were driven by chains from the shaft of a horizontal two-cylinder engine. Fuel for 40 and water for 20 miles were carried. The inventor relates that he drove this vehicle 144 miles from Paris to Douai on less than 12 francs' worth of coke. He averaged 17 m.p.h. over some stretches and thought a maximum of 25 miles was reached at times. Later an American named Gardner joined him, and the Gardner-Serpollet steamers became well known in the early years of the modern industry.

In 1833 a highly ornate coach was brought out by a Dr. Church. This used spring wheels 8.5 ft. in diameter with tires 18 in. wide, and a single smaller wheel in front for steering. Its passenger load was fifty people and it employed a set of full elliptic springs on the front, a distinction from Hancock's carriages which seems to give preference to semi-elliptic. Church seems to have continued his experiments for about 5 years.



Wheels of Progress

Along the New York Central Lines the manufacture of motor cars, the Fourth Greatest American Industry, has arisen to a position of commanding importance within the past fifteen years.

Of the more than 2,000,000 automobiles operated in this country, more than nine-tenths were built in the industrial centers served by this railroad. Plans for the construction of nearly a million new cars in 1916 prove that the motor car has become an economic necessity. It has become the horse of the farm, the truck of industry, the wagon of commerce, the carriage of society, the chariot of war.

It facilitates transportation and expedites business. It brings millions of people within easy reach of the railroad, "the people's automobile." It helps to make travel a pleasure, the purpose and achievement of

The New York Central Lines

The advertisement of which this is a reproduction, recently appeared as a full page in various prominent daily newspapers. It is particularly noteworthy because it shows how greatly the attitude of the railroad companies has changed toward the automobile. A few years ago such an advertisement would have been deemed utterly impossible.

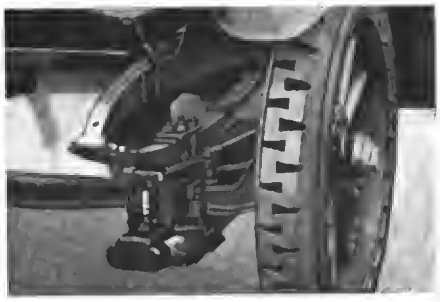
ACCESSORIES

Jones Pneumatic Spring

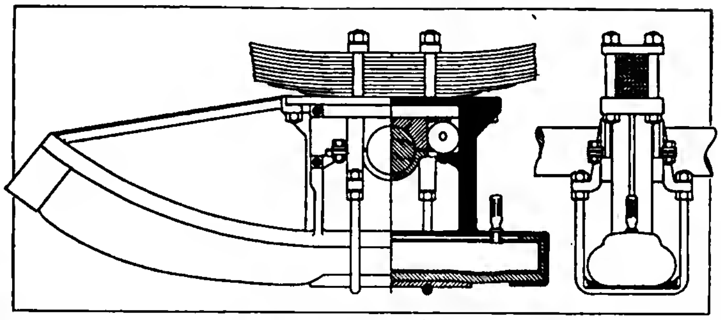
How to secure pneumatic tire action with solid tires is a question which has been the subject of a number of inventions during the last few years. A very ingenious method of solving the question is suggested by the Jones Pneumatic Tire Spring Co., which, as the name implies, incorporates the pneumatic action with the spring, although the car itself is equipped with solid rubber tires.

In other words, the Jones pneumatic tire spring utilizes the principle of the pneumatic tire as a cushion but takes it away from the road, thus eliminating wear on the pneumatic unit from riding friction, blowouts, rim cuts, punctures and other familiar tire troubles. The device can be atached to any car without mechanical changes and as suggested by the illustration, this is done by simply removing the spring clips and installing the Jones axle clips.

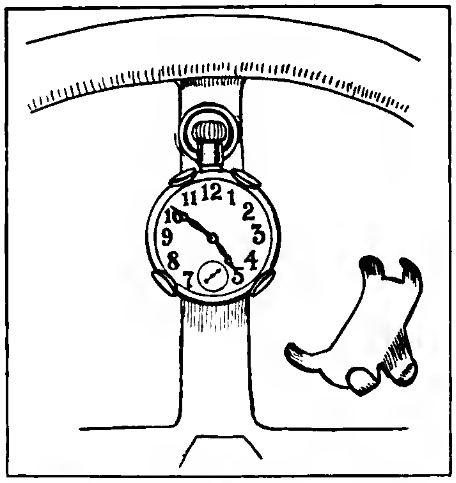
As shown by the illustration, the pneumatic cushion is slung beneath the axle in such a way that the upward or downward thrusts on the spring are communicated to it by the pneumatic medium, while the car itself is equipped with solid tires. The pneumatic units are not subjected to any wear except that due to cushioning shocks and they can be kept to any desired pressure by inflating through the valves with which they are equipped. The Jones pneumatic springs are $150 a set, except for Fords for which car they sell for $50 per set.—Jones Pneumatic Tire Spring Co., New York City.



Jones Pneumatic Spring



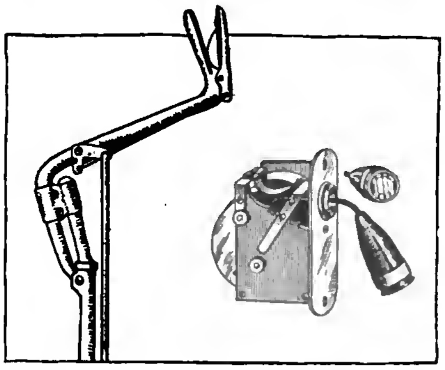
Section of Jones Spring



Jay & Dee watch and holder on wheel

Jay & Dee Watch Holder

This watch holder is a felt-lined one-piece steel clamp, down-turned fingers of which grip one arm of the steering wheel, while four upturned fingers clasp the watch. The clip holds the watch firmly in place, but not so tightly that it cannot be easily detached by a pull when leaving the car. It can then be carried in the pocket, being a standard timepiece with special dial and hands. The watch and clip are not sold separately, the combination listing at $1 each.—Jay & Dee Specialty Co., Inc., New York City.



Left—Grout's lever extension. Right—Electric cigar lighter

Grout's Lever Extension

This is an offset extension for the Ford brake lever which brings the handle 7 in. closer to the driver and makes it considerably easier to manipulate the brake. The latch handle is carried along with the extension so that the brake is used in the same way as with the straight handle. Attachment is made by a clip and a single bolt and the work can be done in a few minutes without fitting or machine work. The device is of steel, finished in black enamel. Price, $3.50.—B. F. Grout, Derby, Vt.

Weaver Bucket Grease Pump

This device consists of a heavy valveless grease pump; is detachably mounted in a large bucket so that it can be used in three ways; grease can be pumped from the bucket into a gearbox or rear axle housing; it can be pumped from a case or housing into the bucket; and it can be pumped from its original can or barrel into the housing, without using the bucket. Valves are eliminated by using ports which are covered and uncovered by a slight turn of the pump barrel. The barrel holds exactly 1 lb. of grease or heavy oil and is 2 in. in diameter, made of heavy brass tubing. The bucket of sheet steel, has a two-part cover, one section sliding within the other, and holds 25 lb. of grease. The hose used is of flexible steel and is ⅝-in. in diameter. The illustrations below show the handiness of the bucket pump. Not only is time saved by using it, but much waste of lubricant. Price, $12.—Weaver Mfg. Co., Springfield, Ill.

Weaver bucket grease pump, showing two methods of using

Detroit Gears for Fords

These special gears are designed to permit an increase of speed where conditions are favorable or to lower the gear ratio of Ford cars for very hilly country, being supplied in one ratio lower than the standard, 3.63 to 1, and three higher. The low ratio is 4 to 1, and the higher ratios 2¾ to 1, 2 4/7 to 1 and 3 to 1, the highest, or 2 4/7 to 1, gear being for racing purposes, the 2¾ to 1 for fast roadsters, and the 3 to 1 for general driving. Gears are nickel steel, hardened and sand blasted, all except the racing type being interchangeable with the regular Ford gears. A little machining is necessary for the installation of the racing gears, instruction for which is furnished. The gears offer a very simple means for saving gasoline as well as for gaining speed, as the use of a slightly higher ratio in flat country, will reduce the fuel consumption in practically the same proportion as the gear has been raised. The gears sell for $15.—Detroit Radiator & Specialty Co., Detroit, Mich.

Cutler-Hammer Grounding Switch

This switch is designed to ground the magneto circuit and so prevent the operation of the car until the ground is removed. The ground is established by pulling out a plug, which is small and may be carried on a key-ring when not in the switch. The switch may be installed in any convenient place. It sells for 76 cents.—Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Dover Offset Funnel

The Dover funnel is designed for filling tanks which cannot be conveniently reached with a straight funnel, its offset spout giving a horizontal reach of 10 in. The spout outlet is ⅞-in. diameter and the top of the funnel 10¾, the capacity of the funnel bowl being 1 gal. The material used is copper-plated steel. The spout is removable for compactness. Price, $2.—Dover Stamping & Mfg. Co., Cambridge, Mass.

Polson's Blow-Out Patch

This blow-out patch is of heavy white friction fabric with red rubber ends, the entire patch being vulcanized over a mold. A flap prevents pinching, the fastening being a self-adjusting strap. When air pressure is applied the patch expands at the ends and tightens in the middle, preventing pouching at the blow-out. The 3-in. size sells for 80 cents; 3½-in., 90 cents; 4-in, $1; 4½-in. $1.20, and 5-in., $1.40. All the patches are 10-in. in length.—Polson Rubber Co., Kansas City, Mo.

Trescot Pocket Testers

The Trescot pocket meters for battery testing are somewhat smaller than the standard Sterling pocket instruments, and, while possessing the same constructional features, are little more than ½ in. thick and 1¾ in. in diameter. They consist of: Ammeter, 40 amp. in 5-amp. divisions; voltmeter, 10 volts in ½-volt divisions; voltammeter, 40 amp. in 5-amp. divisions and 10 volts in ½-volt divisions. The ammeter sells for $1, the voltmeter $1.10 and the voltammeter $1.35.—Sterling Mfg. Co., Cleveland, Ohio.

Ekern's Garage Grease Gun

A new model Ekern's grease gun has been brought out having a heavy seamless steel cylinder 6-20 in. and holding 20 lb. of grease or 2½ gal. of liquid oil. The tank is mounted on wheels. The hose is 5 ft. long and has a special nozzle and shut-off at the end. A scale at the top measures grease accurately and checks the amount used. A new feature is an extra set of gears which makes it possible to bring the piston from the bottom of the cylinder to the top, when the container is empty, at three times the descending speed. The piston is lifted out and swung to one side to fill with grease or oil. The gun sells for $30.—Ekern Bros., Flandreau, S. D.

U. W. Pull-Out Line

This is a steel wire cable for towing work, the hook spliced on each end being fitted with two manila rope slings for making fast to axles to give flexibility in towing and to prevent marring of the finish. The line is 25 ft. long, including the slings in towing position. It sells for $2.—Upson-Walton Co., Cleveland, Ohio.

Materials and Makers

"STAND by us and we will stand by you." This is the attitude that some of the large parts manufacturers seem to be taking toward the makers of raw materials. The concerns which furnish the makers of automobile parts with raw materials know that this shortage is but a temporary one, and it would be indeed foolish and short-sighted for them to raise the price to a prohibitive degree to customers whom they know to be steady and good for business for an unlimited number of years.

This attitude toward the parts manufacturer, who buys in such large quantities that his business is cherished, is the only possible fact that can explain the large number of recruits to the passenger car manufacturing business. These new concerns are all in the assembling rather than in the manufacturing business, and this means that they must be able to purchase parts at prices which will enable them to compete with cars which are built complete in the home factory.

The fact is that the price of materials has not so seriously hampered the parts makers that they cannot continue to sell parts to new concerns. The feeling of fear against serious shortage that was noted a few months back seems to be passing over, and the small manufacturer does not seem in the least worried at the present time.

Chicago Meets Expectations

AS was anticipated on all hands the Chicago exhibition proved to hold few surprises of a mechanical nature. It is practically a repetition of the New York exhibition with hardly a difference in the cars. Reports of the first few days prove that it is a great success, the attendance being good and the scheme of decoration, on which so much trouble has been lavished, voted remarkably effective.

That color in connection with automobiles is beginning again to be considered was indicated in New York, and emphasized at Chicago. The effect of so large a display of bodies with carefully chosen paintwork and upholstery is bound to be great. At both shows it was easy to see that the neatly colored car, not the gaudy eye-stunning creation, but the quiet red or blue or gray, attracted much favorable comment. This means that the public taste is being educated away from the unsuitable black toward a more serviceable and more attractive scheme.

It is unquestionably a fact that dealers find the offer of a choice of color a great advantage, even if the color cost a little more than standard black. Probably this is because it allows a customer to impress his own individuality upon his automobile to some extent, giving him a car that is recognizable from his neighbor's without a critical inspection.

Detail Refinements

IT was pointed out at the recent meeting of the Metropolitan Section of the Society of Automobile Engineers that no radical changes in automobile design had been made during the past year, and that all the changes are in the nature of detail refinements. This is an interesting viewpoint, and at once brings the observer back to the question of what is, and what is not, a radical change. Certain it is that the introduction of the spiral bevel drive, for instance, into the lower-price cars must mean that somewhere someone has found a process which radically cut the price of manufacture of these parts.

So on throughout the entire gamut of changes made during the year. On the car they appear as minor refinements, but each one of them stands for something more than that in the plant of the manufacturer.

The reflection that detail changes have on the whole make-up of the car is a point not to be overlooked. Apparently it makes little difference to the car user if the cylinders are cast in block or singly, but when he stops to consider that the block-cast motor shortens the hood and gives more room throughout the entire body for a given amount of wheelbase it begins to be evident that the change does affect him. Vacuum feed, apparently, is not connected with baggage space, and yet the fact that the tank is removed to the rear allows for much greater carrying capacity under the seat. Each alteration has effected some other part of the car besides that with which it is intimately connected, and while improvements in themselves may be classed as minor, yet the *tout ensemble* has been definitely improved.

Jordan Motor Car Co. Organized

Capitalization $800,000—Company Is Based on Co-operative Plan

CHICAGO, ILL., Jan. 25—The work of organizing the Jordan Motor Car Co. was practically completed at a meeting of the stockholders held here to-day. Two-thirds of the preferred stock issue of $300,000 was subscribed and reservations made for at least one-half of the remainder by persons desiring to distribute it among their friends and business associates.

The company is based on the co-operative idea in which E. S. Jordan, president, has associated with him on a stockholding basis practically all of the dealers who have to date arranged to handle the product; and besides several men interested in the manufacture and sale of components and accessories. To this list have been added the names of several well known advertising and newspaper men. A portion of the unsubscribed stock is being held for prospective dealers who have expressed an interest in the new organization.

The organization prospectus calls for a total capitalization of $800,000, including $500,000 preferred and $300,000 common. Of the preferred $200,000 is being held in the treasury. The common stock is given as a bonus with the preferred on the basis of one-half share to every share of preferred. The preferred pays 7 per cent cumulative and is redeemable at the company's option of two years at 110.

Already all the specifications of the Jordan car have been decided upon and parts for 2000 machines contracted for with the most reliable parts makers, these including such names as Continental, Timken and Brown-Lipe.

The car is a six-cylinder design, the chassis assembled from components as indicated and with particular attention devoted to body design, the lines of which incorporate the latest tendencies in custom body work. Appearance, comfort, power and durability have been aimed at.

New Tire Pump Ready

NEW YORK CITY, Jan. 20—The Edward A. Cassidy Co., Inc., this city, is introducing an engine-driven tire pump under the name of the Cassco. This pump, a single-cylinder device, is listed at $8. It is claimed that the device contains new constructional features, covered by Cassidy patents, which eliminate all piston difficulties. At present fittings are furnished for Buick, Studebaker, Chandler, Chevrolet, Dodge, Reo, Saxon, Overland and Hudson cars. Fittings for other cars are being prepared. The pumps will be ready for delivery Mar. 15.

Three new men have been added within the past week by the company. They are R. G. Ames, G. B. Gosman, and C. P. Brewster. Mr. Ames will cover the Western territory for the company and will make his headquarters in Chicago. Mr. Gosman, formerly assistant general manager of the automobile accessories division of the H. W. Johns-Manville Co., has been elected secretary. Mr. Brewster will cover Pennsylvania and the South for the company.

Burr Leaves Woods Electric

CHICAGO, ILL., Jan. 25—Information has just became public that Louis E. Burr for many years at the head of the Woods Motor Vehicle Co. has severed his connection with that concern.

Mr. Burr resigned early last November. "I left the Woods Co., selling out my interest nearly three months ago," said Mr. Burr to-day. "But it was a part of my agreement not to make the matter public. The company was planning a new car and it was thought best not to announce my retirement from the organization." Mr. Burr now is engaged in the bond business in Chicago.

A. A. A. Assigns Race Dates

NEW YORK CITY, Jan. 22—The following dates have been assigned for automobile contests during the coming season. Those marked * have been assigned official sanction numbers and the other dates are tentatively assigned pending completion of the preliminary requirements under the contest rules:

Date	Event and Promoter
Feb. 22	Speedway—Los Angeles Ascot Speedway Assoc.
May 6	Speedway—Sioux City Sioux City Speedway Assoc.
May 13	Speedway—New York Sheepshead Bay Speedway Co.
May	Speedway—Chicago (Amateurs) Speedway Park Assoc.
*May 30	Speedway—Indianapolis Indianapolis Motor Speedway.
June 10	Speedway—Chicago Speedway Park Assoc.
June 28	Speedway—Des Moines Prince Speedway Co.
July 4	Speedway—Minneapolis Twin-City Motor Speedway Co.
July 4	Track—Coeur D'Alene, Idaho Hiller-Riegel.
July 4	Speedway—Sioux City Sioux City Speedway Assoc.
July 15	Speedway—Omaha Omaha Auto Speedway.
Aug. 5	Speedway—Tacoma. Tacoma Speedway Assoc.
Aug. 18-19	Elgin Road Races Chicago Auto Club.
Sept. 4	Speedway—Indianapolis Indianapolis Motor Speedway.
Sept. 4	Speedway—Des Moines Prince Speedway Co.
Sept. 16	Speedway—Providence Narragansett Park Speedway.
Sept. 29	Track—Trenton, N. J. Inter-State Fair (H. P. Murphy, Racing Sec.)
Sept. 30	Speedway—New York. Sheepshead Bay Speedway Co.
Oct. 7	Speedway—Omaha Omaha Auto Speedway.
Oct. 14	Speedway—Chicago Speedway Park Assoc.
Oct. 19	Speedway—Indianapalis Indianapolis Motor Speedway.

Harding Twelve Announced

New Car to Be Made in Cleveland—Experimental Work Completed

CLEVELAND, OHIO, Jan. 24—The Harding Twelve is Cleveland's newest car. It will be placed on exhibition at 1824 Euclid Avenue within a few days.

F. I. Harding, formerly treasurer of the Peerless Motor Car Co., and W. C. Spaulding, formerly president of a large knitting company, are the founders of the Harding Motor Car Co., which will manufacture and market the Harding car. A number of other prominent business men of this city will be interested in it. At present the offices are on the fifth floor of the Cuyahoga Building, but factory space will be secured at an early date and the company will begin to build cars for the trade.

Has Good Body

In appearance this car is rather foreign. Instead of the straight lines of the streamline car, curves have been used, blending into each other from the radiator through the hood, cowl and body to the rear. This renders the car distinctive, but not freakish. It sets low and is furnished with crowned fenders, cowled back to the front seat and is generally graceful in contour.

The motor of the new car is of the twin-six type. The cylinders, 2¾ by 5, are cast in blocks of six each and the heads are removable. The crankshaft may also be easily removed without disturbing the cylinders, this rendering it very convenient for making repairs and reducing the upkeep.

The carbureter is located on the left side and the starting and lighting units on the right, the V being left clear. The first car is a seven-passenger and it is probable that no other type of body will be built, not this year at least. Later on a roadster may be offered the public if it is seen that there is a call for it after the other car is out.

To Reorganize United Motor Truck

GRAND RAPIDS, MICH., Jan. 21—Prospects are said to be bright for rejuvenating the United Motor Truck Co., which has been in a financially embarrassed state for several months. A committee appointed by creditors to decide upon a feasible plan for overcoming the difficulties has reported that $100,000 of the $150,000 merchandise creditors have replied to letters and that the total will reach $131,000. This figure does not include the $80,000 held by banks and Frank T. Hulswit.

Metropolitan S.A.E. Discusses Show

New York Engineers Debate Developments of 1916 Cars

NEW YORK CITY, Jan. 21—At the meeting of the Metropolitan Section of the Society of Automobile Engineers, held at the Automobile Club of America, the nominations of officers for the coming fiscal year were announced by the nominating committee. The new nominees are Leonard Kebler, president Ward Leonard Electric Co., for chairman; Harry Tipper, advertising manager of the Texas Co., secretary; and H. G. McComb, engineer of the General Vehicle Co., treasurer. The officers held over from this year who will serve on the governing committee for the next fiscal year are R. McA. Lloyd, consulting engineer, present chairman and J. Edward Schipper, technical editor THE AUTOMOBILE, present secretary. Elections will take place at the next meeting which will be held Feb. 17.

The paper discussed at the meeting was entitled "Some Engineering Features of the 1916 New York Show," by H. H. Brown. It dwelt on the detail improvements which have been made during the year, especially in the refinement of parts of the car which have made it more efficient from the owner's standpoint. One of the points commented upon by Mr. Brown is the attention which has been given to the lubrication of the slower moving parts such as the springs, steering knuckles, spring bolts, etc.

Referring to the question of the multicylinder motor, Mr. Brown said:

"While there is little doubt but that the demand for the polycylinder motors over that for the four is largely a matter of style yet it is probably founded on the sound basis of a demand for a flexible car.

"While many of the manufacturers have sought to satisfy this demand by supplying six-, eight- and twelve-cylinder motors for their cars, yet there are others that have realized that flexibility in a car depends primarily on the number of impulses imparted to the drive wheel in a revolution rather than to the crankshaft of the motor.

"These manufacturers have therefore sought to give the public flexible cars by providing the car with a light, well built, well balanced, high-speed motor geared comparatively low on high rather than with one of many cylinders or large cylinder displacement geared comparatively high.

"There is no doubt but that the six-cylinder motor is a better naturally-balanced motor than the four, hence to rival the absence of vibration in the six the advocates of the light high-speed fours have sought to obtain as good balance as possible by refining the details of design and by lessening the weight of reciprocating parts."

The discussion consisted chiefly of comments by the members on the interesting features of development as seen at the show. The more extended use of spiral bevel drive, thermo-syphon cooling, block casting, better brake arrangements and unit power plants excited particular interest. The absence of the transmission brake was also commented upon.

Gloetzner Vice-President Bour-Davis

DETROIT, MICH., Jan. 25—A. A. Gloetzner, assistant chief engineer of the Chalmers Motor Co., has joined the Bour-Davis Motor Car Co., Detroit, where he will have full charge of the purchasing and engineering departments. He is also vice-president of this new company.

Mr. Gloetzner has been actively connected with the production and engineering end of the automobile industry for about thirteen years. He was at one time assistant production manager of the Olds Motor Works. He also was factory manager of the Krit Motor Car Co. and also of the Owen Motor Car Co.

Bradfield Velie Sales Manager

MOLINE, ILL., Jan. 22—F. E. Bradfield, who has been associated with the Velie sales department almost since the inception of the Velie Motor Vehicle Co., has been appointed to the position of sales manager and will hereafter have jurisdiction over the entire sales organization. He will be assisted in his work by G. H. Lloyd, long connected with that company's sales, which to date, are over 400 per cent greater than those of a year ago.

Dunlap Chandler Sales Manager

DETROIT, MICH., Jan. 25—J. M. Dunlap will becomes sales manager of the Chandler Motor Car Co., Cleveland, Ohio, on Feb. 1. Mr. Dunlap was the organizer of the Dunlap-Ward advertising agency here, which had charge of the Chandler advertising campaign during the last two years.

Studebaker to Retire $2,308,500 of Serial Notes

DETROIT, MICH., Jan. 22—The Studebaker Corp. has called for payment on March 1 of the remaining $2,308,500 of its 5 per cent serial notes. This wipes out the last of the $8,000,000 note issue sold March, 1912.

Grant Increases to $4,000,000

Originally Capitalized at $100,000 and Raised to $200,000

CLEVELAND, OHIO, Jan. 25—The Grant Motor Car Co., Findlay, Ohio, is to increase its capital stock from $200,000 to $4,000,000, of which $3,000,000 will be common stock, the shares having a value of $10, while $1,000,000 will be 7 per cent cumulative convertible preferred stock, of $100 value per share. Of the common stock $1,000,000 is reserved for the conversion of the preferred stock and the total authorized outstanding stock is thus $3,000,000.

The preferred stock is now offered to the public by Andrews & Co., investment brokers in Chicago and Detroit, at $105 with a bonus of 20 per cent in common stock. The 7 per cent preferred stock is convertible into an equal amount in par value of common stock, that is ten shares of common for one share of preferred, at the option of the holder at any time prior to Jan. 1, 1919. It is preferred over the common stock as to dividends and in the event of dissolution and liquidation, is entitled, in priority to the common stock to repayment in cash at 120 per cent and accrued dividends.

According to a statement of President D. A. Shaw, of the Grant Motor Car Co., the earnings of the company during 1915 were about $165,000. The number of cars shipped was 4,006 while in 1914 the total shipped was 2164. The production for 1916 calls for 12,000 cars and the net earnings are estimated at $720,000 for the year. Beginning July 1, 1916, it is expected that production will be increased on a basis of 15,000 cars annually.

The investment of the company in plant, machinery, tools, etc., is reported to be only $79,239.66, which small amount enables the assets to be current and liquid at all times, and makes rather large earnings possible on a small capital investment. The company started in business in 1913, with a capital stock of $100,000 which was doubled later.

Ray Harroun Leaves Maxwell

DETROIT, MICH., Jan. 24—Ray Harroun, of the Maxwell Motor Co., who built the Maxwell racing cars and was especially interested in the racing end of the engineering work, has resigned, and will, it is said, devote his attention to the Maxwell racing cars now owned by Carl G. Fisher and himself. No successor has been appointed as yet.

Baltimore Territory Needs 40 Per Cent More Automobiles for 1916

Tenth Annual Show Is Highly Successful—Closed Cars in Strong Demand—Registrations in District Have Increased Over 66 Per Cent

BALTIMORE, MD., Jan. 24—Statistics gathered at the show staged in the Fifth Regiment Armory, Jan. 18 to 22, by the Baltimore Automobile Dealers' Association and the Automobile Club of Maryland reveal that the territory controlled by Baltimore dealers will absorb between 25 and 40 per cent more cars during 1916 than were absorbed in 1915. In actual figures, the State of Maryland registered in 1915, 27,858 pleasure cars, 3189 commercial vehicles and 1341 dealers. The total registration up to date shows that already there have been registered some 10,460 pleasure cars, 2124 commercial vehicles and 913 dealers. These figures include both the State of Maryland and the District of Columbia, and represent an increase of nearly 66 2/3 per cent for the same period last year.

Is Retailers' Show

The show was the tenth annual event to be staged in the city, and from a monetary point of view it was by far the most successful. All told, some 60 dealers of pleasure cars and commercial vehicles had exhibits, and as an indication of the size of the show suffice it to state that there were on view 157 pleasure cars and 71 trucks. Wednesday was the big day, the attendance figures totaling more than 9000, and even on Thursday, which was Society day and for which the admission charge was 50 cents instead of 25 cents, more than 6000 persons passed the ticket takers. The attendance figures for the week were approximately 20 per cent ahead of those for any previous year.

The show is essentially a retail function. Some few dealers and subdealers are appointed by some of the larger distributers who have space, though for the most part it is the Baltimore city dealer who has the exhibit. Accurate figures regarding the number of sales made at any show always are difficult to obtain, though from the reports of exhibitors it appears that sales were quite satisfactory and in many instances greatly exceeded expectations.

Not the least significant feature of the show was the great demand for closed cars and particularly for open cars which are fitted with detachable tops. That the advent of these detachable top cars has had a noticeable effect in bolstering up the sales curve during a time when it ordinarily drops considerably, cannot be gainsaid. In some cases dealers who have not been able to get detachable top jobs from their factories have shifted their representation to be able to offer them.

Another noteworthy feature is the great interest which Baltimore is taking in the commercial vehicle. Up to comparatively recently Baltimore pavements have not been what might be termed excellent, and this has had a depressing effect on the commercial vehicle industry. Now, however, Baltimore is probably one of the best paved cities in the country and this undoubtedly has had some effect in helping sales of trucks. There are at present 11,046 one-horse vehicles in Baltimore and 5025 that are drawn by two horses. These figures are practically the same as for the year 1913. Just how the motor vehicle is supplanting these is

Value of Baltimore's Industries

	2,228	115,767	353,319,086	73,980,084	279,339,002

revealed by the truck registrations, which for 1915 were 3189, whereas up to date, for 1916, the number is 2124 and gives evidence of eventually showing an increase of considerably better than 66 2/3 per cent.

Covers Seven Counties

The average territory controlled by the Baltimore dealer embraces seven counties—Anne Arundel, Baltimore, Carroll, Cecil, Harford, Montgomery and Howard—with a total population of 295,755; some dealers have more territory, a few of the large distributers having the whole State of Maryland, and some have a little less. And throughout the whole of this territory business prospects are bright, for, as a trade center, Baltimore is growing rapidly. For example, the bank clearings last week totaled $44,418,957, as against $37,120,124 for the corresponding week last year. The increase has been consistent, and, if continued, will show a large gain for the year.

The population of Baltimore, according to the last census figures, is given as 558,485, though there is a project afoot at present to increase the size of the metropolitan district to give a total population of more than a million. Maryland is essentially a farming State, more than 82 per cent of the land area being included in farms, and of this about 68 per cent is improved. It may not be generally known that the State stands second in the canning industry and is led only by California. More than 40 per cent of the tomato pack of the United States comes from Maryland. The single industry of second rank is men's clothing, and this centers largely in Baltimore.

Baltimore Is Prosperous

At the present time, Baltimore is enjoying the wave of prosperity that is sweeping over the Southern States. In the opinion of dealers at the show, this section of the country is entering on a period of unprecedented prosperity, and as an indication of the possibilities of the territory the figures which are given herewith and which cover Baltimore's diversified trade interests are illuminating. These are taken from an industrial survey of the city which was brought to a close in December, 1914. Since that time a number of large industrial interests have located in Baltimore, though no figures are available as to their trade importance.

Jobbing Trade, $250,000,000

Baltimore's jobbing trade, not including the commission business, reaches $250,000,000 yearly. The leading items are dry goods and notions, millinery, clothing, boots and shoes, hats and caps, drugs, groceries and food products, all of which show large increases over the figures given in the United States Census report for 1910. In addition, there are grain and shipping figures of over $100,000,000 and a commission business of a like figure. As an indication of the grain trade, it is pointed out that Baltimore received in 1914 60,770,082 bushels of grain and 1,808,672 barrels of flour. Baltimore's imports for the calendar year were $35,533,814 and the exports were $117,269,378.

Following are figures which give the extent of the motor car industry in the State of Maryland and the city of Baltimore at present, from figures compiled by the Automobile Trade Directory:

	Maryland	Baltimore
Dealers	166	60
Repair shops	34	24
Garages	67	50
Supply dealers	31	30

Mason Tire & Rubber Co. to Be $1,000,000 Corporation

KENT, OHIO, Jan. 22—At a meeting of the board of directors of the Mason Tire & Rubber Company this week, a resolution was adopted to increase the capital stock to $1,000,000, and a meeting of the stockholders will be called within a short time to approve this step. According to a statement made after the meeting, building contracts have already been awarded.

Stutz Doubles Plant

INDIANAPOLIS, IND., Jan. 24—Work has commenced on a new four-story building, 80 by 208, of the Stutz Motor Car Co., which will give it double its present manufacturing capacity. The new building is being erected immediately north of the present plant and the contracts call for completion of the building, which will be a duplicate of the present factory, by June 15. President Harry Stutz says that this new building will make it possible for the company to manufacture more of the parts entering into the car which are at present purchased outside. The new factory will be an insurance against any possible tie-up due to shortage of certain parts.

Harry Bill Vice-President of Springfield Body Co.

NEW YORK CITY, Jan. 24—Harry Bill has become vice-president and general manager of the Springfield Body Co. and will have charge of production. Mr. Bill has been connected with the Hayes Mfg. Co., Detroit, in charge of production.

Elliott Leaves United Motor Truck

GRAND RAPIDS, MICH., Jan. 24—E. M. Elliott has resigned as vice-president and general manager of United Motor Truck Co., Grand Rapids, Mich. His future plans have not been announced.

John A. Hill Dies Suddenly

Famous Publisher Did Much to Develop Technical Journalism

John A. Hill, president of the Hill Publishing Co., died suddenly from heart disease on Monday morning, Jan. 24, while traveling in his automobile from his residence in East Orange, N. J., to his place of business.

Mr. Hill was fifty-seven years of age, having been born on Feb. 22, 1858, in the town of Sandgate, near Bennington, Vt. While a young lad his parents emigrated to central Wisconsin and he was educated in the public schools there. He had a liking for mechanics, however, and after some years in a printing office he became half owner of a machine shop, where he carried on repairs to a variety of local machinery. In 1878 he removed to Colorado and ran a locomotive on the Denver & Rio Grande R. R. for a time.

His bent toward journalism and the printing office was shown by his founding in 1885 the "Daily Press" of Pueblo, Col., which journal he edited for some time.

A number of his articles were contributed to a modest sheet called "Locomotive Engineering," which was published in New York by a company which also published the "American Machinist." In 1888 Mr. Hill was invited to come to New York and take charge of "Locomotive Engineering." Under his charge the journal rapidly increased in importance. Seeing the possibilities in the enterprise, Mr. Hill associated himself with Angus Sinclair, purchased the journal from its owners and undertook to carry it on as a separate publication. In this venture Mr. Hill was both editor and publisher, and his genius was well proved by the phenomenal success of the publication. Its subscription list grew by leaps and bounds, and it rapidly assumed the leading position in its field.

In 1896 Mr. Hill sold his interest in "Locomotive Engineering" to his partner, Mr. Sinclair, purchased the "American Machinist" and laid the foundation for one of the largest enterprises in the field of technical publication ever established.

At that time practically all class publications had their printing done by contract and were limited by such facilities as the printers were willing to provide. Mr. Hill's early experience in the printing business had given him a strong liking for this side of the publishers' work, and he was ambitious that his publication should be able to own and operate its own printing plant. In order that such a printing plant shall be commercially successful, however, it cannot concentrate its work upon a single journal, but must be able to distribute it over a number.

It was this situation among others which led Mr. Hill to add to the successful "American Machinist" other well-established technical journals of high reputation. His first purchase was "Power." Later the "Engineering and Mining Journal" passed under his control. In 1912 he purchased the "Engineering News" from its founder and chief owner, George H. Frost.

To carry on these various publications Mr. Hill organized the Hill Publishing Co., in which, while he held the largest interest, a number of those associated in the conduct of the various journals were also stockholders. A fifth journal, "Coal Age," was established in 1911 to cover a field which it had become evident was too broad to be successfully reached by the "Engineering and Mining Journal," chiefly devoted to metal mining interests.

An enterprise in which Mr. Hill took great pride and to which he devoted some of the best energy of the last years of his life was the construction on the west side of New York City of the great building to house his publications, which was completed in 1914.

Montreal Show Is Social Function

MONTREAL, Jan. 22—The third annual Motor Show, held under the direction of the Montreal Automobile Trade Association, Limited, was opened to-night by His Honor the Lieutenant Governor of the Province of Quebec, and took place in the basement of Almy's store, where every inch of the 20,000 sq. ft. floor space available was occupied. If the opening night is any criterion as to attendance, it is safe to say that the social recognition formerly given to the Annual Horse Show will be transferred to the Motor Show. The number of cars on exhibition reaches 75, while there are 45 exhibitors at this year's show. A considerable number of commercial trucks are on exhibition which last year were apparently lacking in numbers. Several new cars were shown for the first time, including the National, Davis, Grant, Saxon, Canadian, Briscoe, Crow and Chevrolet.

H. A. L. Ready to Produce

CLEVELAND, OHIO, Jan. 24.—The space leased by the H. A. Lozier Company in the old Royal Motor Car factory aggregates 59,000 sq. ft. The building is protected by a sprinkler system, and the natural and artificial lighting systems are of the best. Contracts for material were all awarded some time ago and the company will go right forward in the manufacture of the H. A. L. 12.

Stevens Bill in Mass Meeting

Bill Before Congress Intended To Prevent Price Cutting

NEW YORK CITY, Jan. 22—A mass meeting to discuss the Stevens Bill was held at Madison Square Garden yesterday in connection with the pure food and drug exhibit. The bill provides that manufacturers may legally fix the price at which their products shall be sold and is designed to eliminate price cutting. Several speakers dwelt on the merits of the bill and the evils of price-cutting, mentioning many specific instances of where a fixed price for a trade-marked article resulted in benefits to manufacturer, retailer and consumer.

WASHINGTON, D. C., Jan. 21—Under the title "To protect the public against dishonest advertising and false pretenses in merchandising" Representative Dan V. Stevens, of Nebraska, to-day reintroduced in the House of Representatives the original Stevens-Ayres bill with a number of important amendments designed to meet the views of many friends of the measure.

The new bill specifically permits discounts for cash and for quantity and for allowances and rates covering costs of transportation. The latest tally shows 209 members of the House in favor of this legislation, which is but nine less than a majority.

90 Per Cent of Cars in Cuba Are American

SANTIAGO, CUBA, Nov. 18—There is a constantly increasing demand for automobiles in Santiago and throughout this consular district. Most of the city and suburban roads are macadamized, and although made several years ago, are in excellent condition. Ninety per cent of the cars already in use are of American manufacture, the remainder being chiefly Italian and French. The greatest demand in this section is for a low or medium priced, strongly built car with a serviceable top for protection against the heavy rains as well as the sun.

Paraguay Sees First Truck

ASUNCION, PARAGUAY, Nov. 11—A representative of an American truck company, who is now traveling in South America, brought to Asuncion on Sept. 22 the first motor truck that has ever been in the Republic of Paraguay.

Numerous demonstrations of the truck were given. The President of the Republic, the Ministers of War and Interior rode on the truck over one of the worst roads and were favorably impressed. It is probable that several of these trucks will be purchased here. There is a plan on foot to form a transportation company using motor trucks to serve districts not on the railway or river, whose sole means of communication at present consists of bullock carts and pack animals.

Send Catalogs to Venezuela by Mail

WASHINGTON, D. C., Oct. 29—Automobile and parts manufacturers who are sending catalogs and other advertising matter to Venezuela will benefit by the latest report from the United Export Bureau, which states that if the above matter is sent by parcel post it is subject to duty, whereas it is admitted free when sent by mail. When a firm in Venezuela is called upon to pay 40 to 50 cents or more as duty on the catalog of some American maker, sent by parcel post, the usual result is that the catalog is refused and the maker in the United States wonders why his advertising in Venezuela brings little business.

Motoring in France Now Less Difficult

PARIS, Dec. 30—Continuing the relaxation of automobile restrictions outside the actual army zone, the military authorities have given orders that the gates of Paris shall remain open to automobiles until midnight instead of 10 o'clock, as previously. After 12 o'clock only taxicabs without passengers aboard, and going to or from their garages, are allowed through the city gates.

The annual automobile census, to take place this year during the month of December, will be more stringent than usual. Every owner is under an obligation to declare his car to the local authorities, who communicate the lists to the military, and in addition the police and gendarmes have been instructed to keep a look out for hidden cars or trucks. For several months there have been few or no requisitions of private cars, for the army is able to obtain a reasonable number of touring cars from the home factories and supplies from America are available, if required. Unless there are unexpected developments, it is doubtful if the private car owner in France will receive any further attentions from the military. The military registration scheme which allowed any man's car to be seized at a moment's notice was very useful in the first rush of the war, but now that fighting has become almost an established business, it is found more advantageous to go to the factories rather than to individual owners.

Regulations regarding touring are also less stringent outside the active army zone. Instead of fortnightly, monthly military passes are given to car owners. These passes are asked for by the police every time an automobile goes through the gates of Paris, but on the open road are only required to be presented at rare intervals, and principally in directions leading to the war zone. In the center, West, South, and Southwest parts of France there are hardly any more restrictions than under peace conditions. A register is maintained in each district of all automobile passes issued, and if any driver is reported as having made an illegal use of his pass he is caught when he presents himself for the monthly renewal. The very simple remedy is to refuse to renew the pass, and as no driver dare run without a permit, an effective control is maintained.

For the war zone exceptionally stringent regulations are in force. Civilian motorists can only travel in this district on obtaining a pass issued by the commanding officer, bearing the photograph and signature of the driver and each passenger, the number of the car and the precise itinerary to be followed. Each military driver not forming part of a convoy, must also possess a special pass, renewable at frequent intervals. As there are guards along the roads with orders to stop all cars, whether carrying civilians, private soldiers or officers, it appears to be impossible for any unauthorized person to travel by automobile in the war zone of France. Any attempt to break through, or to get through with a false pass would entail the confiscation of the car and court martial.

Private motorists outside the war zone are not experiencing any shortage of tires, except a few of the very large and little used dimensions. The standard sizes, such as 105 mm. and 120 mm., which are the two most commonly used, are obtainable in big quantities from practically all the makers, and at normal prices. The gasoline shortage which was rather serious has passed away, and the price has dropped slightly. There is still, however, a feeling of irritation against the big refiners who are popularly believed to have taken advantage of the war to boost the price of gasoline.

Dividends Declared

Willys-Overland; quarterly of 1½ per cent on common, payable Feb. 1 to stock of Jan. 22.

Cincinnati Speedway Gets Land

CINCINNATI, OHIO, Jan. 15—The Cincinnati Speedway Co., which is building a 2-mile board speedway, reports that it has already sold $410,000 worth of stock and has taken an option on a land site. Plans are at present being developed for the track and buildings and the speedway representative is studying the Sheepshead Bay track at New York.

"All Steel" Touring Car to Cost $425

New Machine Planned to Be Ready in August This Year

ST. LOUIS, MO., Jan. 15—The plant of the All-Steel Motor Car Co., which is being built at Macon, Mo., will be ready for operation early in April it was announced here to-day, following the annual meeting of the officers and stockholders of the company. The company plans to put out a touring car, including starter and electric lights for $425. If present plans are realized the All-Steel car will be on the market early in August.

E. J. Spencer resigned as president of the company at this meeting and his successor has not yet been named. The new directorate, it is announced, will include Charles L. Smith, designer of the car; Fred V. L. Smith, treasurer of the company; Oscar A. Trorlicht, secretary; Edward F. Stockho, Andrew C. Duncan and John Hambeacon. Louis Goodhart, formerly traveling representative of the Lewis Spring & Axle Co., manufacturers of the Hollier-Eight, has been appointed sales manager of the All-Steel company.

The company will occupy the plant formerly occupied by the Blees Carriage Co. at Macon, Mo., including four buildings and covering a city block 380 by 300 ft.

Salesmanship Congress at Detroit July 2

DETROIT, MICH., Jan. 24—From July 2 to 6 Detroit will entertain several hundred visitors who are expected to participate in the first "World's Salesmanship Congress" which will be held at the Detroit Board of Commerce.

As might well be expected the automobile industry will have a big share in this event and many prominent men connected with it are either members of the executive committee or of special committees. Among those who are executive members are Hugh Chalmers, president of the Chalmers Motor Co., Harry W. Ford, president of the Saxon Motor Co., Norwell A. Hawkins, manager of sales of the Ford Motor Co., E. Leroy Pelletier, advertising manager of the Reo Motor Car Co. and the Reo Motor Truck Co., W. C. Standish, resident manager of the U. S. Tire Co.

Mr. Pelletier is chairman of the publicity committee of which the other members are Lee Anderson, commercial manager of the Hupp Motor Car Co., Frank G. Easton, advertising manager, Packard Motor Car Co., Theodore F. MacManus of the Dunlap-Ward Advertising Co., Frank V. Martin of the Banker & Martin Co. and Julian C. Weed of the Timken-Detroit Axle Co. Among the members of the finance committee are Paul Smith, sales manager of the Chalmers Motor Co. and L. D. Robertson, manager of the Detroit branch of the Packard Motor Car Co.; H. H. Hills, general sales manager of the Packard Motor Car Co., is a member of the arrangements committee.

McCulla Returns to Packard

DETROIT, MICH., Jan. 22—W. R. McCulla, will return to the Packard Motor Car Co. Feb. 1. About a year ago he left Packard to take the position of assistant chief engineer of the Knox Motors Co., Springfield, Mass., and has been in Europe much of the time studying war truck conditions for his company. Prior to that he was associated with Packard in the research engineering department, coming to this company from the Hudson Motor Car Co., where he had been in the experimental end of the business. McCulla will resume research engineering work at the Packard factory, specializing on aviation.

Bayerline & Daly's New Car

DETROIT, MICH., Jan. 22—Details of the new car that is to be built by the manufacturing concern formed by J. T. Bayerline, former president and general manager of the King Motor Car Co., and W. L. Daly, who was general sales and advertising manager of the same concern have been divulged in part. It is understood that the car is to be a six-cylinder, 3¼ by 4½, to sell at $900 as a five-passenger. The wheelbase will be 114 in., tires 32 by 3½. Rear springs are cantilever, the axle floating, the clutch a multiple disk. The price of $900 is to include a convertible top, in addition to the regular equipment.

Trailer Steers with All Four Wheels

FLINT, MICH., Jan. 22—Nickle Bros. who have a wagon shop here have brought out a new automobile trailer which it is claimed has many novel features. Each of the four wheels is placed on a circle similar to the fifth wheel of an ordinary wagon. The left hind wheel and the right front wheel are connected through long rods. Also the right rear wheel with the left front wheel so that when the front wheels are turned in one direction the rear truck turns the opposite way, the wheel traveling upon the circumference of a circle the diameter of which may be as small as 20 ft. For the present the trailer is made with only a light wagon type of body to carry a load of 1500 lb. Heavier style bodies will be made. The members of the firm are William J. and Samuel Nickle, veteran wagon builders.

Portage Sales Increase

Tire Co. Closes Prosperous Year—Slashes Goodwill Figure by $100,000

BARBERTON, OHIO, Jan. 24—The Portage Rubber Co., this city, has just issued a report to its stockholders which states that the company's directors have marked down their valuation of the company's trademarks, patents and good-will $100,000. It is stated that the board contemplates further reduction from time to time.

The company has sent out a condensed balance sheet as of Nov. 30 last, which shows gross sales for the twelve months ended on that date were $1,067,858, as against $661,848 the previous year, showing an increase of 61.3 per cent. Total profits were $129,005, as against $88,102, an increase of 46.4 per cent. The balance sheet follows:

Assets	
Cash	$60,185
Receivables	250,697
Stock on hand (raw and finished)	284,842
Real estate and plant	337,979
Trademarks, good-will, patents	496,000
Other patents	15,536
Total	$1,445,240

Liabilities	
Payables	$10,807
Reserve (depreciation)	6,992
Preferred stock	750,000
Common stock	500,000
Surplus	177,441
Total	$1,445,240

Markets Easier

NEW YORK CITY, Jan. 25—Market prices last week were easier. Prices on those commodities which have seen violent rises during the past few weeks, either remained constant or were lower. Steel prices were unchanged, though the big demand by the manufacturers was as urgent as it has been during the past few weeks. The lead and copper markets, however, continue to rise, the former closing yesterday at $6.10 per 100 lb. and the latter at 25 cents a pound. Tin on the contrary, rose yesterday to $42.50 per 100 lb. or a net gain of $1.37 for the week. This metal has always been subject to violent changes, however and so the latter rise cannot be taken as a mark of further violent changes.

The rubber market was quiet last week and prices were somewhat unchanged. Para which earlier in the week reached the 88-cent mark, declined to 86 cents, yesterday, and the Ceylon pale crêpe made a gain of 1 cent, making the closing price 93 cents. There was a large demand for rubber all during last week.

Gasoline in this city remained dormant, closing at 22 cents a gallon. No new features developed in the refined situation last week. There was no further chartering of freight room for export of the oil, but the domestic demand continued good. Cold weather is still interfering with the development work in the Eastern fields, according to advices from Pittsburgh. The few wells to reach completion are located in the old districts and all are light or dry. There is no improvement in the size of the late completions in the southeastern Ohio fields.

$500,000 Garage Combine in Cincinnati on Novel Plan

CINCINNATI, OHIO, Jan. 14—Steps are being taken to form a combination of seven garages in Cincinnati and Covington, which will be controlled by a corporation with $500,000 capital stock. Those interested in the movement are W. L. Voight, William Junclas, C. Sandman and Col. P. Wing.

Plans for the latest garage in the combine have been completed. It will be located at Fifth and John Streets and will cost about $35,000. It will be a two-story building and will have entrances on both Fifth and John Streets.

It is planned that the stockholders, instead of paying monthly rental for keeping their cars both in the suburbs and in the downtown section, will pay but one rental and will be permitted to use any garage in the combine.

French Exhibition Planned for May

Big Scheme on Foot to Hold Show of French and American Industry in Paris

NEW YORK CITY, Jan. 24—Although the end of the war is still in the distance the nations whose territory has been overrun and destroyed are already thinking and planning for the reconstruction of the devastated cities, towns, villages and farms. To assist in this matter several European nations have already sent commissions to various countries to ascertain what these various countries can supply to meet the great need. It goes without saying that it will cost a great deal more to repair the damage done than it has cost to defend against the damage. The French commission has been in America for many weeks making examinations of American goods and capacity. In an interview in Washington in December, Monsieur Damour made the following statement:

"It is our hope and purpose with the co-operation of American manufacturers to reconstruct the industries of France and re-develop its agriculture along the most modern lines. Above all to install machinery of the latest type to take the place not only of the men and horses which will be lacking at the end of the war, but of the old methods, and to enable her to produce her specialties in a most economic fashion. The Chamber of Deputies is now sending men all over France to make investigations into conditions to find out just how many machines will be required and what improvements in building and equipment can be best installed."

Every country in Europe whether belligerent or neutral, is in very great need of practically everything in the line of machinery and building materials. One of the reasons for this condition is that it has been the custom of the European countries each to depend upon the other for a large percentage of their needs and now owing to the war and the impossibility of either manufacturer or communication with the markets of Europe of every country are wanting in a large percentage of their requirements. This condition will doubtless continue for a long time after the war closes.

It is stated that the exposition has been financed in a manner satisfactory to the Government of France. For a partial reimbursement of this expense the American exhibitors will be charged eight francs per square meter for space plus 1 per cent of the sales contracts made during the exposition. Space for outdoor exhibits will be much less. Space will be reserved in response to cable or letter and one-half the price of the space must be paid on the allotment of the space and the other half at any time previous to May 1. All money should be sent to the Administrateur General Edouard Tijou, 16 Rue Taitbout, Paris. For everything else intending American exhibitors are referred to Henry C. Long, 5 Opera Square, Paris.

Should the plan be successful it should offer an opportunity to American truck manufacturers as their product is absolutely essential to reconstruction of the kind considered by the promoters of the scheme.

Receiver Appointed for P. R. Mfg. Co.

DETROIT, MICH., Jan. 24—Pending the hearing which has been set for March 17 in the Wayne County Circuit Court, the Security Trust Co. has been appointed receiver for the P. R. Mfg. Co., which makes the Zephyr carbureter and auto parts. It appears that some of the stockholders desire that the company be dissolved while others are opposed to this action.

Larrabee Elected President

BINGHAMTON, N. Y., Jan. 14—H. C. Larrabee was elected president; R. H. Deyo, vice-president and general manager; S. T. Macey, treasurer, and I. T. Deyo, secretary, at the recent annual meeting of the Larrabee-Deyo Motor Truck Co.

Dividends Declared

Stewart-Warner Speedometer Corp.; quarterly of 1¾ per cent on preferred and 1½ per cent on common, both payable Feb. 1.

Automobile Issues Active

General Motors and Chevrolet Strong with Substantial Gains—Packard Down

NEW YORK CITY, Jan. 25—The automobile and accessory securities showed more activity last week and prices were higher. A strong tone developed during the latter part of the week and several of the issues showed marked gains.

General Motors and Chevrolet, which have been more or less prominent on the stock exchange on account of the proposed merger, came to the fore last week with gains of 21 and 10 points, respectively, General Motors reaching 486 and Chevrolet 132. It is stated by a few of the holders of General Motors that many of the people interested in that stock are holding it at the present time until it reaches the 500 mark. Firestone and Kelly-Springfield Tire common showed considerable strength. It is stated of the latter company that trading in its issues will start on the local exchange early next month. The application will be made just as soon as the new certificates are ready.

The new stock will not share in the dividend payable Feb. 1. The company, it is stated, will probably show earnings for the year ended Dec. 31 last of over 28 per cent for the common stock.

International common and preferred showed a substantial gain for the week. The common went up 7 points, while the preferred rose 3 points. This company last year closed one of its most successful periods. Domestic sales in December, it is stated, made a new high record, and for the full 1915 year home business increased 20 per cent over 1914. Peerless stock went up 8½ points on rumors of placing that issue on a dividend basis within the next few months.

A few of the stocks, however, made considerable drops in prices. Packard common went down 22½ points, while that of Studebaker dropped 3¼ points. Texas stock dropped 13 points; Willys-Overland common closed 4 points lower. Maxwell, U. S. Rubber, Stewart-Warner, Swinehart Tire, Goodrich and Chalmers, showed decreases ranging from a fraction to 2 points.

General Motors and Continental Motor featured the Detroit issues with gains of 25 and 13½ points, respectively. The market on the whole was stronger last week, with the exception of one or two stocks, which were lower on both the Detroit and New York exchanges. These were Packard and Maxwell. Packard common dropped 21½ points on the Detroit exchange, and the Maxwell stocks all showed small losses.

Gasoline Selling at 29 Cents in New York

NEW YORK CITY, Jan. 25—At the present moment in New York 30-cent gasoline is not an actuality; but 29-cent gasoline is. That is to say, some distributers are asking that much for it. Tank-wagon gasoline is 22 cents; garages are selling it for from 25 cents up —nearly always up, and considerably so.

Last August the tank wagon price was 14 cents in New York; thus the advance is 8 cents, or a little more than 57 per cent.

*Old. †New. ‡And accrued dividends. §Par value $10. ¶Ex dividend.

Over in Newark the tank-wagon price is 21 cents; it was 11 cents last August. The lower price in Jersey is attributed to the fact that transportation across the Hudson is quite an item. The ordinary ferries and car ferries will not take the inflammable stuff, so it has to be ferried across the Hudson in special lighters, in steel barrels; it cannot be unloaded from the lighters until it can be loaded directly on trucks; and it must be emptied direct from the barrels, one by one, into the dealers' tanks. Then the empty barrels have to be returned whence they came.

The New York price is not the peak price, however. In Tucson and Douglas, Ariz., the price is 22.5 cents; in Boston it is 23 cents; and Santa Fe, N. M., seems to roost on the pinnacle with 25.5 cents, tank-wagon.

Chicago tank-wagon gas is 16.5 cents; last August it was 10.5 cents. For Minneapolis the corresponding figures are: 16.5 and 11.5; for New Orleans, 17.5 and 12; for Omaha, 15 and 10; for Philadelphia, 21 and 13; for Portland, Me., 22 and 15 and for Portland, Ore., 16.5 and 12.

Cleveland is paying 16 cents, Cincinnati, 21 and Chicago, 16.5; Los Angeles pays 16 and San Francisco, 15; Pittsburgh, 22; St. Louis, 15.9 and Kansas City, 15.8; Seattle is at the bottom of the list with 14 cents—an increase of only 2 cents since last August.

The reasons to which the price rise is attributed are more or less obvious with one or two exceptions. The large increase that has taken place in the employment of farm tractors is responsible for a considerable increase in the demand for fuel; in Central Illinois, for instance, the farmers keep their tractors going all the year round. The huge increase in the number of cars used is a vital factor; there were about a million and a half cars in use a year ago, and now there are about two millions. It is anticipated that next summer there will be close to two and three-quarter millions, all using gasoline at the rate of about 500 gal. a year. That makes a great many gallons—1,375,000,000 of them.

The refiners' plaint is that the cost of crude has increased enormously and that the crudes yielding the greatest percentage of gasoline are the scarcest; moreover, the percentage of gasoline yielded is decreasing, taking the country as a whole. Roughly averaging the country's crude product, it will yield about 12.5 per cent of gasoline; 17 per cent is considered a very good proportion indeed, and some oils are not worth working for the gasoline they will give.

The war—of course—is mixed up in it, for the supplies from Russia which came through the Dardanelles are cut off and the strain on the home industry increased just so much.

Five More Tire Rises

Ajax, Fisk, Hardman, McGraw and Federal Announce Increases from 10 to 20%

New York City, Jan. 22—Five more tire companies have fallen in line with the price increases of the other concerns, started by the Kelly-Springfield company around the first of Jan. The latest are Ajax, Fisk, Hardman, McGraw and Federal, making a total of sixteen. It is expected, however, that several of the remaining concerns have already adjusted their prices to a new schedule. One of the companies, namely, the Republic, announcement of whose increase in prices was made last week, instead of making a general increase, has merely adjusted its prices, in some cases the prices being as much as a dollar lower on its plain tread type. The non-skids, in the majority of the sizes, are about 10 per cent higher.

The rearrangement of prices of the five new tire companies to announce increases range from 10 to 20 per cent. The largest increase was made by Hardman, whose prices are 10 to 20 per cent higher. Ajax ranges from 10 to 15 per cent; Fisk is 10 per cent higher, and Federal is also 10 per cent higher.

A number of the tire companies which did not announce an increase in prices were swamped with orders from those automobile owners who wished to lay in a supply of tires before the rise.

This increase of prices, it is stated, will not cover the increases that have already taken place in the prices of crude rubber and other materials used in the manufacture of tires.

Although the majority of the companies have increased the prices on most of the popular-sized tires, a few of them have in some instances made no changes whatever. For instance, the Hardman company has made no changes on the 30 x 3½ and 31 by 3½ non-skid. The 32 x 3½ non-skid has only been raised 10 cents, from $26. The Republic company has made a change on its 28 x 3 plain tread, the price going up 10 cents.

The following lists will give the prices on a few of the popular-sized tires:

FISK

Plain Tread			Non-Skid		
Size	New Price	Old Price	Size	New Price	Old Price
30 x 3½	$12.75	$11.60	30 x 3½	$13.40	$12.20
34 x 4	21.35	19.40	84 x 4	22.40	20.35
36 x 4½	30.10	27.35	36 x 4½	31.55	28.70

HARDMAN

30 x 3	$15.00	$14.10			
36 x 4	34.00	29.60	36 x 4	$41.50	$36.20
36 x 4½	42.30	38.10	36 x 4½	50.00	42.30

FIRESTONE

28 x 3	$9.80	$8.90	28 x 3	$10.95	$9.95
36 x 4	23.00	20.90	36 x 4	25.75	23.40
37 x 5	39.10	35.55	37 x 5	43.80	39.80

REPUBLIC

28 x 3	$10.70	$10.60	28 x 3	$12.40	$15.15
30 x 3½	14.80	14.75	30 x 3½	17.35	21.70
34 x 4	24.80	23.80	34 x 4	29.10	31.15
36 x 4½	35.00	34.20	36 x 4½	41.00	41.85

DIAMOND

Popular sizes increased 10 per cent; other sizes 25 per cent. Advanced Jan. 18.

30 x 3½	$12.75	$11.60	30 x 3½	$13.40	$12.20
34 x 4	21.35	19.40	34 x 4	22.40	20.35
36 x 4½	30.10	27.35	36 x 4½	31.60	28.70

FEDERAL

Popular sizes increased 10 per cent; other sizes 15 per cent. Advanced Jan. 18.

30 x 3½	$13.40	$12.15	30 x 3½	$14.75	$13.95
34 x 4	22.40	20.35	34 x 4	24.65	23.40
36 x 4½	31.60	28.70	36 x 4½	34.75	33.00

McGRAW

Popular sizes increased 10 per cent. No increase on other sizes. Advanced Jan. 18.

30 x 3½	$12.75	$11.60	30 x 3½	$13.40	$12.20
34 x 4	21.35	19.40	34 x 4	22.40	20.35
36 x 4½	30.10	27.35	36 x 4½	31.60	28.70

NASSAU

No advance yet. Advance expected Feb. 1.

Austrian Tire Made of Wood Fiber

Vienna, via London, Jan. 15—An Austrian engineer named Von Dunikowski has applied for a patent on a tire, consisting of wood fiber and certain binders. The specifications show that the tire follows the old pneumatic principle in every detail, there being an inner tube and an outer tire. The main material used is willow and birch fiber. What the binder consists of has not ben revealed, but it is known that no rubber whatever is used. It is stated that an automobile fitted with the new tires ran 437 miles and showed no signs of undue wear.

Materials Cramp Tractor Output

Moline, Ill., Jan. 18—The Moline Plow Co. reports a marked scarcity in raw materials needed in the manufacture of tractors, resulting in a marked handicap in the production of this machine. Orders are heavy, but lack of steel and the difficulty in getting orders filled, due to the heavy demand on account of the war abroad, promises to greatly reduce the output of the Moline plant. Some varieties of steel have increased 60 per cent in price, while one grade has advanced 70 per cent. Despite the fact that prices for machines must necessarily be increased proportionately to the cost of steel and other raw materials, business does not appear to be affected.

Gasoline from Gas in Texas

Dallas, Tex., Oct. 23.—Several plants for the manufacture of gasoline from natural gas will be built in Texas within the next few months. It is stated there are now about fifty plants in Oklahoma manufacturing gasoline from casing-head gas, or gas which comes direct from the well with crude oil, formerly a waste product. The total output of these Oklahoma plants is about 80,000 gal. of gasoline daily. In California there are said to be about twenty plants of this kind with a total daily capacity of 35,000 gal. It takes about 500 cu. ft. of gas to yield 1 gal. of gasoline.

Armored Cars for N. Y. State

Squadron Expected to Be Ready in April—Eight Cars in All

NEW YORK CITY, Jan. 24—The armored motor car squadron to be presented to the State of New York by a group of prominent men is expected to be ready by April. It will consist of eight armored battle and cruiser cars, including an officers' car, tool car, tank car and emergency car. This will be the first armored car squadron in America, and since the plans for the enlargement of the United States army call for motor cars of a similar type it is expected that this will be a stimulus to the national equipment.

The donors of the cars are E. H. Gary, Henry C. Frick, Robert M. Thompson, Dudley Olcott, James N. Wallace and Harry G. Montgomery. In all the plans for the squadron no expense has been spared. The steel for the cars is the standard United States 0.3-in. bulletproof gun-shield metal. The frames are built by the American Bridge Co. and the chassis include two Macks, two Locomobiles, two Whites and two Jeffery quads. The commanding officer's car will be built especially for speed. Full electrical equipment is carried and a searchlight on each car will sink into a box when not in use. In order to provide for quick maneuvering the cars will be able to move backward at full speed as well as forward.

Farmers Own 14 Per Cent of Pennsylvania's Automobiles

YORK, PA., Jan. 20—The growing popularity of the automobile on the farm is demonstrated by the fact that Pennsylvania farmers own more than 14 per cent of the automobiles registered in the State during the past year. On the first of the year there were 22,608 automobiles in the hands of the farmers of the State, according to the estimates of the bureau of statistics of the department of agriculture. The reports show that 9.5 per cent of the farmers are car owners and this means that there is an automobile on one out of every ten farms. A year ago it was estimated that there were 15,000 automobiles in the hands of farmers of the State.

In 1915 there were 159,984 automobiles registered in Pennsylvania and the farmers are shown to own 14.1 per cent of that total. Many of the registrations granted by the State were for cars owned by non-residents and the percentage of farmers owning cars is likely to be much higher if the total number of State owners could be ascertained. The rural residents undoubtedly led by a fair margin all other classes as purchasers of cars during the year.

In ten out of sixty-seven counties the reports show that from 15 to 18 per cent of the farmers own cars and in thirty-one counties 10 per cent more of the farmers are shown as car owners. Lancaster county leads with more than 18 per cent of the farmers owning an estimated total of 1842 cars. Chester county farmers own 1019 cars and Bucks county farmers 963 cars. In many counties during the year gains of 100 per cent in the number of farmers owning automobiles were common, while in some counties the gain was from 150 to 200 per cent.

Wilmington Wants High Grade Cars

WILMINGTON, DEL., Jan. 24—Prominent in connection with the second annual show of the Wilmington Automobile Trade Association, held here last week, is the fact that the entire Delmarvia Peninsula is under the influence of an unprecedented wave of prosperity. The demand for automobiles has been beyond the dealers' ability to make prompt deliveries.

The most remarkable fact in connection with the industry here is that 75 per cent of all high grade cars sold are to du Pont employees. All makes together are purchased by these people to the extent of about 25 per cent. These employees a little over a year ago were clerks and mechanics earning a moderate salary but to-day are worth many thousands of dollars.

President J. H. Nixon, of the association, states that there is a larger percentage of high grade cars in the State of Delaware than in any other State in the Union and that sales possibilities are great. He substantiated this statement by saying that the per capita wealth is greater than in any other American city.

Must Not Wash Cars with Gasoline

YORK, PA., Jan. 22—The announcement by Fire Chief Harry L. Wills, of this city, that it is the intention of the State to rigidly enforce the act of 1914, providing regulations for the use, storage, sale and keeping of gasoline, naptha and kerosene, will affect more than a score of garages and automobile dealers in this city. The act provides that no person may wash automobiles or any part of an automobile with gasoline or naptha. This will not bar kerosene. One of the clauses set forth in the act is that suitable fire extinguishers must be kept on hand at all times by dealers in oil as well as a box of sand with suitable scoop to scatter the sand.

Vesta Electric Transmission Announced

Clutch and Gearset Replaced by New Device—Direct on High

CHICAGO, ILL., Jan. 24—A new Vesta centrifugal electric generating clutch will be announced later this week by the Vesta Accumulator Co., Chicago. The idea is the combination of the electro-magnetic drag between the armature and fields of any electrical machine and direct friction connection such as is obtained in the ordinary clutch. The Vesta clutch replaces the usual cone or disk clutch, the gearset, the flywheel, the electric generator and the starting motor.

The Vesta system is no new thing in principle, having been brought out in crude form by its inventor, William Morrison of the Vesta company, as long ago as 1898, and described in an engineering magazine at that time.

The system is composed of two parts, the armature and the field, the former constituting the flywheel of the engine and the latter mounted on the forward end of the propeller shaft. The fields are internal and rotate on bearings on the crankshaft extension within the armature. The armature carries an internal commutator and the fields carry the brush holders, the brushes pressing against the internal commutator.

It is in the mounting of these brushes that the real hub of the new idea is incorporated. The brushes are mounted in such a way that the centrifugal force of their rotation, increases the force with which they press against the commutator, in just the same way that the balls of a fly-ball governor swing out with increased speed. When the engine is still the pressure is very light, but as the speed of the car increases the pressure of the brushes against the commutator also increases, until, at high speed there is no slip between the armature and the field. That is, we now have a mechanical clutch, carbon against copper.

Must Label Upholstery in Milwaukee

MILWAUKEE, WIS., Jan. 20—A new law passed by the Wisconsin Legislature of 1915, and effective Jan. 1, 1916, which has generally escaped notice, but is of wide importance, is Section 1418s—3m relative to upholstering or repairing the upholstering of motor cars. The law now in effect requires the branding or labeling of the upholstery to show the kind of materials used. It is regarded as a measure to promote sanitation. The statute reads as follows:

"Any person upholstering or reupholstering any furniture or automobile box-spring or any other article or thing whatsoever, or who manufactures for sale, offers for sale, sells or delivers or who has in his possession with intent to sell or deliver any goods or article of any kind containing upholstering, without a brand or label as provided in subsection 3n of this section, or who removes, conceals or defaces the brand or label thereon, shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine of not less than twenty-five dollars ($25.00) nor more than five hundred dollars ($500.00), or by imprisonment in the county jail not to exceed six months, or by both such fine and imprisonment.

"(3n) The brand or label provided in subsection 3m of this section shall contain, in plain print in the English language, a statement of the kind of materials used in the filling and in the covering of such upholstery or reupholstery, to be specified in true terms according to the grades of filling and covering used by upholsters or reupholsterers, whether such materials are, in whole or in part, new or secondhand, the qualities of the materials used, and whether the materials used, if second hand, have been thoroughly cleaned and disinfected. Such brand or label shall be in the shape of a paper or cloth tag to be securely fastened to each article upholstered or reupholstered."

The effect of the statute on manufacturers of motor and other vehicles can readily be discerned. Up to this time there has been no report of violations or arrests, but the situation is such that it should be watched very carefully by manufacturers and dealers.

New Sheridan Light Truck

Chicago, Ill., Jan. 22—Numbered among the new commercial car makers is the Sheridan Commercial Car Co., with headquarters in Chicago and factories at Harvey, Ill., which is bringing out a new light commercial car to sell at $465. It will be equipped with a 2 by 4-in., four-cylinder engine, block-cast, with removable cylinder heads. The carbureter is a Carter, the magneto, Bosch, the clutch a cone and the cooling is by thermo-syphon.

The gearset is selective with two forward speeds. The rear axle is of the floating type and the car is geared 5 to 1 on high, 12 to 1 on low and 12 to 1 on reverse. The maximum speed is said to be 30 m.p.h. The wheelbase is 104 in. In the matter of equipment is found windshield, horn, tools, Prest-O-Lite tank, headlights, delivery body, 43 in. wide, 65 in. long and sideboards 8½ in. high. This body comes with top and side curtains.

British Import Tax Has Small Effect

Greatly Increased Quantities of Parts Going from U. S. A. —Gasoline Importation Reaches Record

London, Jan. 8—In commenting upon the effect of the new British import duty of 33 1/3 per cent on automobiles and parts thereof, the *Times*, which is the leading newspaper of Great Britain, says:

"Although the matter is not one for which definite statistics can be given, in the opinion of men qualified to judge the demand for motor cars continues brisk. Second-hand cars by reputable makers and in reasonable condition command good prices, and such new cars as are available readily find purchasers. As the makers in this country—and the same is true in France—are devoting most of their energies to purposes other than the production of cars, or if they are making cars these are not available to the ordinary buyer, it follows that the demand can not be satisfied from home sources; and in these circumstances American manufacturers, who are said to have turned out over 600,000 cars during the past 12 months, have been enjoying a golden opportunity.

33⅓ per Cent Has Small Effect

"The import tax of 33 1/3 per cent to which certain motor vehicles of foreign manufacture have been subjected since the end of September on entering this country has, however, introduced a new factor. In September last, according to the Board of Trade returns, the number of complete cars and chassis imported for sale was 2661, with a value of $2,519,771, whereas last month the number fell to 1806 and the value to $1,622,515. The figures for last month are far above those for the same month of last year, when the number of cars and chassis was 336 and their value $460,663; but in view of the disturbed conditions existing last autumn perhaps a fairer comparison is with October, 1913, when the number was 1119 and the value $1,232,855. In September, 1914, the figures were 197 and $212,792, and in the same month of 1913 they were 1156 and $1,290,454. If the effect of the tax, as indicated by the figures for last month, is not so great as might be expected it must be remembered that the returns do not distinguish between cars intended for private use, which have to pay the tax, and those for commercial purposes, which do not; and for anything the official figures show the falling off may have been chiefly, if not entirely, in the former category.

"In passing it may be noted that the tax appeals to different sections of the motor-car trade in very different ways. Manufacturers can regard it with equanimity, at least; and though it can have no immediate effect on firms which are not at the moment making cars for ordinary sale, it may help to secure their position against the time when they are able to start producing again. But to the retailers or agents, through whom in normal times the bulk of the cars made in this country are distributed to the public, the matter presents itself in another light. They rely for much of their livelihood on the profits they receive from selling cars, and if they have no cars to sell those profits naturally disappear.

Gasoline and Parts Are Up

"As regards motor-car tires and tubes and their accessories, which are exempt from import tax, the figures for the last two months are almost identical, the value being $1,401,270 in September and $1,398,992 in October; but the value of 'other parts,' which are taxed, actually increased from $705,088 in the former month to $1,097,989 in the latter. These figures do not suggest any reduction in the total volume of motoring; and the statistics of the imports of motor spirit, the other chief item besides tires in the running expenses of a car, point to the same conclusion. In September 9,879,103 gal. were imported and duty was paid on 10,766,314 gal., while last month the quantity imported reached the enormous total of 15,982,832 gal. and duty was paid on 10,251,373 gal."

Dry Batteries to Be Dearer

Milwaukee, Wis., Jan. 22—That the price of the standard dry battery will advance soon and that material advances are to be expected within the year, was the statement of O. E. Rhuoff, of the French Battery & Carbon Co., Madison, Wis., before the annual convention of the Wisconsin Electrical Contractors' Association in Milwaukee. Mr. Rhuoff attributes the advancing prices to the increasing difficulty in obtaining materials and the heavy demand created by the European war.

Ford's Milwaukee Plant Opened

Milwaukee, Wis., Jan. 25—The new Milwaukee plant of the Ford Motor Co. was formally opened on Monday, Jan. 24. The company has experienced considerable difficulty in getting delivery of its machine tool equipment because of the enormous demands upon machinery builders. However, the plant will begin operations on schedule time. A. W. L. Gilpin, manager of the Milwaukee Ford branch, will manage the new works, which represent an investment of $285,000.

Michigan Is Great Sales Territory

Prosperity of Country Offsets Poor Roads—114,000 Automobiles Registered in State

DETROIT, MICH., Jan. 21—The coming season will be one of the biggest Michigan automobile dealers have ever had. Last year would have been a big year if more cars had been available, but practically every dealer was unable to get enough to supply the demand. This year, however, many of the dealers are stocking cars in anticipation of the spring demand and all of them estimate that their 1916 business will exceed that of 1915 by anywhere from 50 to 300 per cent.

The importance of Detroit as an automobile distributing center is not at all commensurate with its place in the industry. Although it is the automobile capital and is known the world over for its automobiles, the distribution of cars through branches and dealer establishments is not of large proportions.

This is due to the fact that the territory is limited geographically. To begin with, the State is cut in two by water. The lower peninsula is hemmed in on the west by Lake Michigan and on the east by Lake Huron and there is no direct rail connection between Detroit and the upper peninsula without passing through other distributing cities. It is possible, of course, to ship cars from Detroit to the upper peninsula by ferrying the freight cars across the Straits of Mackinaw, but shipping facilities to the upper peninsula are much easier out of Chicago or Milwaukee. Also the western part of the upper peninsula is easily reached from Duluth, which city is making a strong bid for recognition as a distributing center in all trades.

Because of this the distribution by dealers in this city is practically limited to the lower peninsula. Also there are in the lower peninsula several important cities, such as Grand Rapids and Saginaw, which are recognized by the factories as distributing points.

In Flint and Jackson are a number of automobile factories and considerable distribution in the State is done from these points. Fifty miles to the south of Detroit is Toledo, which in many cases includes in its distributing territory the southeast corner of Michigan. Chicago, at the lower end of Lake Michigan, also cuts into the State, some of the distributers in that city including a number of Michigan counties in their territory.

Some of the Detroit distributers have a territory that is quite limited. In some cases it includes only three counties. A few have the entire State, but practically none make an attempt to do much with the upper peninsula. The number of dealers used in covering the lower peninsula varies.

While the territory is limited geographically it is a productive area and will add its quota to the increased automobile sales of the country for the coming year. The agricultural interests of the State are diversified and it probably is generally unknown that the State leads in the production of rye, beans, dry peas and chicory. It is second in small fruit and apples; third in pears, grapes, buckwheat and sugar beets; fourth in potatoes, peaches and cherries, and is only ninth in oats, eleventh in barley, twelfth in wheat and fifteenth in corn.

As to live stock its comparative standing is: Sheep, eighth; dairy cows, tenth; poultry, eleventh; bees, thirteenth; horses, fourteenth; cattle, fifteenth; swine, nineteenth.

From these statistics it is at once apparent that the State is healthfully productive in that it is not dependent upon any one staple for its wealth. The crops for 1915 exceeded those of 1914 by more than $4,000,000 in nine principal products which are shown for three years in the following table:

MICHIGAN CROPS VALUE

	1915	1914	1913
Corn	$38,080,000	$42,210,000	$37,595,000
Wheat	20,652,000	17,835,000	11,371,000
Oats	22,491.000	22,838,000	17,550,000
Rye	5,138,000	5,402,000	3,324.000
Potatoes	11,729,000	13,213,000	17,808,000
Hay	42,188,000	36.132,000	33,012,000
Barley	1.555,000	1,521,000	1,265,000
Buckwheat	626,000	748,000	630,000
Beans	12,792,000	11,086,000	7.892,000
	$155,251,000	$150,985.000	$130.447.000

The prospects for 1916 in agriculture are encouraging and some statisticians go so far as to say that 1916 in the western part of the State will surpass all preceding years. Considerable new ground was cleared last fall and a greater acreage than ever before will be under cultivation when the snow goes away. The Grand Rapids and Indiana Railway Company maintains an agricultural and industrial department which is doing much to develop the section to which it is tributary. The company's agent has advised that the railroad will furnish without cost enough sugar beet seed to plant one-quarter of an acre to all farmers who make request. The only condition is that the agricultural work be carried on according to the company's instructions.

The good roads movement that has made such headway in Wayne County is spreading through the State and the automobile people look forward to the day when the State shall have a network of good roads. The truck people especially see a wonderful development in that business when the roads are better. As it is now many farmers are using trucks, but the development of sales among these buyers has hardly begun.

The tractor is looked upon as a coming business, especially the small farm machine. A truck man stated as his belief, based upon years in the implement and truck business, that the automobile dealer would be the tractor dealer of the future except in those tractors which are made by implement manufacturers. These companies, he said, will turn the factory business over to their implement dealers because in so doing they can take advantage of an existing organization.

The number of cars registered in Michigan during the past few years follows:

1909	11,718
1910	18,355
1911	27,796
1912	39,579
1913	54,366
1914	76,322
1915	114,845

Automobile Reserve Corps for St. Louis

ST. LOUIS, MO., Jan. 19—The question of organizing a St. Louis branch of the proposed National Automobile Reserve will be placed before the entire membership of the Automobile Club of St. Louis at a meeting early in February, it was announced here to-day by F. M. Flesh, president of the club. The club has a membership of about 3000 motor car owners.

Secretary Morse of the club, with a view of obtaining the sentiment of other automobile clubs, wrote to organizations of nearly every big city in the country and the answers he received indicate that a majority of the automobile clubs are strongly in favor of an automobile reserve.

Over 100 Cars at York Show

YORK, PA., Jan. 21—At least $500,000 worth of automobiles will be exhibited at the first annual automobile show of the York Automobile Dealers' Association to be held in this city Feb. 1 to 5. More than 100 cars, it is estimated, will be shown by the score or more of automobile and automobile accessory dealers in this city.

Iowa Loses Its License Tags

DES MOINES, IOWA, Jan. 22—Two carloads of automobile number plates for the State of Iowa have been lost in transit between St. Paul and Des Moines, and as a result the State automobile department is 25,000 number plates behind its orders for 1916. The number of registrations for the year already has passed 65,000.

Factory Miscellany

Standard Welding Adds—The Standard Welding Co., Cleveland, Ohio, is building an addition to its plant at 1280 West Seventy-third Street, that will cost about $15,000.

Perfection Spring Buys Land—The Perfection Spring Co., Cleveland, Ohio, has purchased two parcels of land adjoining its present buildings on which an addition will be built.

Nice Ball Bearing Co. Formed—B. G. Nice, Frank Beemer, S. W. Nice, George Wells and George Hoppes of Philadelphia are the incorporators of the Nice Ball Bearing Co., which is being organized to manufacture anti-friction bearings and machines for that purpose.

Sporub Tire Co. Formed—The Sporub Tire Co. has been organized in Milwaukee to manufacture and market a new type of puncture-proof tire employing a resilient filler to take the place of the usual inflated inner tube. Offices and store have been opened at 721 Grand Avenue, Milwaukee. Rudolph Fischer is general manager.

Avery Buys Kingman Plant—The Avery Co., Peoria, Ill., manufacturer of tractors and farm machinery, purchased the plant of the Kingman Plow Co., this week for $80,000, being the largest bidder. The Kingman plant will be used for foundry and warehouse purposes. The Kingman plant covers 14 acres and is located but a short distance from that of the Avery plant.

Sieverkropp Engine Starts Work—The Sieverkropp Engine Co., Eighteenth and Clarke Streets, Racine, Wis., manufacturing gasoline engines, self-starters and other devices and appliances for the automobile trade, has started work on the erection of a plant of its own at DeKoven Avenue and the North-Western tracks, Racine. The site is 185 by 154 ft., and the first unit of the new plant will be 50 by 100 ft. The concern intends to erect another shop upon the completion of the factory. About 75 to 100 employees will be added to the payroll as soon as the extensions are completed.

Large Chevrolet Plant for Oakland—The largest automobile plant on the Pacific coast, the Oakland Chevrolet assembling plant, is to be under construction within a few weeks. The plant is to be located on the electric loop tract close to the Foothill Boulevard, Oakland, Cal. The factory is to have a capacity of 15,000 cars per annum and will cost more than $200,000. Active work on the plant is to begin before Feb. 1, and the buildings are to be completed by May 15.

Wallis Tractor in Racine—The Wallis Tractor Co., formerly of Cleveland, Ohio, has completed the removal of the plant and offices to Racine, Wis. The company is backed mainly by Racine capital and has been manufacturing a gasoline tractor known as the Cub at Cleveland for two years. The Cub tractor recently traveled cross-country 1000 miles from Cleveland to Fremont, Neb., to the National Power Farming Demonstration. The removal was made to obtain more manufacturing space and better shipping facilities than were available in Cleveland.

The Automobile Calendar

Jan. 25-29	Lancaster, Pa., Show, Conestoga Park Pavilion.
Jan. 22-29	Montreal, Que., Show, Almy's Bldg., Automobile Trade Assn., Ltd.
Jan. 22-29	Chicago, Ill., Show, National Automobile Chamber of Commerce; Coliseum and First Regiment Armory.
Jan. 24-29	Buffalo, N. Y., Show, Buffalo Automobile Dealers' Assn., Broadway Auditorium.
Jan. 24-29	Scranton, Pa., Passenger Car Show, Town Hall.
Jan. 24-30	Portland, Ore., Show, Armory, Portland Automobile Dealers' Trade Assn.
Jan. 25, 26, 27	Montgomery, Ala., Show, Klein Bldg., Montgomery Automobile and Accessories Dealers.

Sept. 15	Indianapolis Track Race.
Sept. 16	Providence Track Race.
Sept. 30	New York City Sheepshead Bay Race.
Oct. 7	Omaha Track Race.
Oct. 14	Chicago Track Race.

The Week in the Industry

O'Neil Fisk's Lowell Manager—C. C. O'Neil has been appointed manager of the Lowell, Mass., branch of the Fisk Rubber Co. of New York whose factory is in Chicopee Falls, Mass.

Ashcroft U. S. Tire Publicity Mgr.—R. W. Ashcroft, of the Canadian Consolidated Rubber Co. of Montreal, has accepted the appointment of manager of publicity of the United States Rubber Co. of New York.

Culver Heads Overland Zone in Atlanta—The Willys-Overland Co. has opened a zone headquarters office in Atlanta, Ga., in the former Locomobile building on Peachtree Street. The office will be in charge of E. N. Culver.

Dunne Now Buick Superintendent—G. W. Dunne, former assistant manager of the drop forge plant of the Buick Motor Co., Flint, Mich., is now superintendent of the Muskegon (Mich.) plant of the Continental Motor & Mfg. Co.

Williams Shifts to Kansas City—W. S. Williams, who was manager of the Studebaker Corp. branch in Dallas, Tex., has been promoted to manager of the more important branch at Kansas City, Mo.

L. B. Alford, who was assistant branch manager in Dallas, is now branch manager, and W. D. Lacey, who was wholesale salesman at the branch, is now assistant branch manager.

Kidder Promoted—E. H. Kidder, who has been manager of the Boston branch of the United States Tire Co. for some years, has been advanced to New England manager, having charge of Boston, Providence, Worcester, Bangor, Portland and Manchester offices with headquarters at the Boston office. J. C. Toomey, manager of the Providence branch, has been brought to Boston to have charge of that territory and H. E. Crocker has been placed in charge of the Providence branch.

Headley Promoted—J. P. Headley, who has been acting for some time as assistant zone supervisor of sales for the Maxwell Motor Corp., has been promoted to the position of special representative, with headquarters in Detroit. His work will be almost entirely in the field and he will travel constantly over the Southeastern States. The Maxwell Company has leased the building at 165 Peachtree Street, Atlanta, Ga., and has sent one of its most experienced salesmen here as manager. C. H. Batchelor will have charge of the salesrooms in that city.

Motor Men in New Roles

Johnson New Seattle Mgr.—Edward Johnson has succeeded J. E. Shellenberger as manager of the Seattle branch of Hughson & Merton, Pacific Coast accessory firm.

Cole Makes Change—W. C. Cole, formerly manager of the used-car department of the Hudson-Phillips Motor Car Co., St. Louis, Mo., has become associated with the Packard Missouri Motor Co. of the same city.

Glazier Wichita Truck Mgr.—J. L. Glazier of Portland, Ore., has been appointed manager for the Wichita Truck Co.'s branch in that city, which will control the Oregon, Washington, Idaho and British Columbia territory.

Johnson St. Louis U. S. Tire Mgr.—O. S. Johnson has been appointed manager of the St. Louis branch of the United States Tire Co., succeeding H. H. Hubbard, who has been transferred to the home office of the company.

White Goes to Toledo—T. W. White, formerly manager for J. W. Leavitt & Co., Overland distributor in Seattle, Wash., has left the Western field for Toledo, Ohio, and will enter the foreign department of the Willys-Overland Co.

Scott Willard Distributor—Sam Scott of Tacoma, Wash., has been appointed exclusive distributor for the Willard Storage Battery Co. for this city. Mr. Scott has organized the Storage Battery Supply Co. He is located with the Pacific Car Co.

New U. S. Branch Mgr.—Howard E. Crocker has been appointed manager of the Providence, R. I., branch of the United States Tire Co. John Toomey, former manager, has been promoted to the management of the Boston branch of the company.

Three Studebaker Men Promoted—Three changes in the Studebaker organization, each in the nature of a promotion, are announced by The Studebaker Corp.

W. S. Williams, formerly manager of the Dallas, Tex., branch, has been appointed manager of the larger branch at Kansas City. Mr. Williams was retail sales manager for the L. Markle Co., Studebaker dealer in Chicago, previous to becoming branch manager in Dallas.

L. B. Alford succeeds Mr. Williams as the Dallas branch manager. Mr. Alford leaves the post of assistant branch manager, which he held for several years.

W. D. Lacey is advanced from wholesale salesman to assistant branch manager in Dallas, succeeding Mr. Alford.

Little Transferred to N. Y. by Bowser—E. J. Little, who has been manager of the Fort Wayne sales district of the S. F. Bowser Oil Tank & Pump Works for the past five years, has been promoted to the managership of the New York office. Mr. Little succeeds H. C. Carpenter, who has taken charge of the Atlanta, Ga., office. It has been decided to divide the Fort Wayne district, and make out of it the Michigan, Ohio and Indiana districts. L. L. Walker will have charge of the Ohio district. Mr. Walker has had charge of the Philadelphia office. A. S. Bowser, secretary of the company, will look after the Michigan sales district and J. W. Burrows will have charge of the Indiana district. Mr. Bowser has been in Albany, N. Y., for the past several months in the interests of the company, and J. W. Burrows has been chief clerk in the sales department. The Philadelphia office will be discontinued.

Russell-Dewey Co. Formed—The Russell-Dewey Co. has been incorporated with offices at 1790 Broadway, New York City, 1024 Wabash Avenue, Chicago, and Watertown, Mass. The officers are M. A. Dewey, Jr., president, for many years sales manager for N. B. Arnold, Brooklyn, N. Y., manufacturer of Slikup Specialties; C. A. Russell, treasurer, formerly sales manager for Hopewell Bros., manufacturers of the Hopewell tire case and other fabric specialties, and C. A. Hillers, secretary, for the past eight years salesman and New England manager for Hopewell Bros.

The company will act as selling agents for the following companies:

N. B. Arnold, Slikup Specialties; Croxford Auto Rim Tool Co., rim tools; Double Seal Tire Valve Co., tire valves; Flint Motor Plate Co., specialties for Fords; Gibson Hollister Mfg. Co., Jumbo spark plugs; Hopewell Bros., fabric specialties; United Engine & Mfg. Co., garage and shop equipment; Woodbridge Chemical Co., Air-In-Al for punctures. All of which lines will be marketed solely through the jobbers.

M. A. Dewey will make his headquarters at Chicago; C. A. Russell at New York, and C. A. Hillers at Watertown, Mass. These men will cover the Dominion of Canada, and the United States, east of the Rocky Mountains.

Recent Washington News Items—Jamieson Motor Car Co., Spokane, Wash., have been named distributors for Pathfinder and Pullman cars. Salesrooms have been opened at 1229 Second Avenue. Associated with Mr. Jamieson is C. A. Dudley, as salesmanager. The company has secured the territory from the Cascade Mountains east in Washington, north of Salmon River in Idaho, and the State of Montana as far east as Butte.

Doud-MacFarlane Machinery Co., Tacoma, have recently added two modern machines to facilitate repair work. One will be a cylinder grinding machine capable of grinding from one to six cylinders at a time. The other will be an automatic gear cutting machine, which will cut any size or style of gears.

George Clark and A. C. Olson have formed the Motor Force Co. for the manufacture of a new hydrocarbon product, which is declared to be highly efficient. Salesrooms have been established in Seattle at Pike and Melrose Avenues.

The Auto Tire Repair Shop, Tacoma, Wash., is city distributor of Kelly-Springfield and Republic tires, in addition to making a specialty of quick and efficient repairs of all makes of tires.

H. C. McCulloch, of 1431 Broadway, Seattle, has been appointed Seattle agent for the Federal tire.

The Sunset Electric Co., 606 East Pike Street, Seattle, has been appointed Seattle service station for Gray & Davis starting and lighting systems. The firm also acts as service station for Exide batteries.

Agency for the Gordon tire has been placed with the Pacific Tire & Rubber Co., 604 East Pike Street, Seattle.

Philadelphia Trade News—Alterations are being made at 1617 Chestnut Street, Philadelphia, which when completed will be occupied as a local branch by the Maxwell Sales Corp. of Detroit. The branch will be under the management of L. G. Peed, for five years with the sales organization of the company.

The Philadelphia branch of the H. W. Johns-Manville Co., on North Second Street, is being moved to its new modern home at Broad and Race Streets, recently completed.

H. H. Kirkpatrick of Philadelphia has been made branch manager of the Hardman Tire and Rubber Co., 809 North Broad Street, this city.

The Willard Storage Battery Co., Cleveland, has opened a branch and service station at 1434 Brandywine Street, Philadelphia, and has placed in charge P. M. Evans, who for several years has been chief chemist of the company.

Canadian News Items—The Tyre Shop, Vancouver, B. C., has opened at 1015 Blanshard Street under the management of W. Tergeson, formerly with the Auto Supply Co. and S. V. Marks, manager for the Tait Tire Co. A modern vulcanizing plant has been installed and all makes of tires will be handled.

The Western Oil & Supply Co., Vancouver, B. C., has been appointed agent for Savage tires and is opening a store at 427 Howe Street.

The Colonial Tire & Rubber Co., Ltd., Vancouver, B. C., has given up the agency for Michelin tires and is now handling Goodyear tires.

The Johns-Manville Co. has opened a new store and offices on Portage Avenue, corner of Edmonton Street, Winnipeg, Man. J. Papineau has been appointed sales manager.

Denver Trade Items—The Quick Service Tire Co. is the name of a new Denver concern formed by J. A. Rayment and E. M. Tucker, formerly salesmen respectively for the Dry Climate Tire Mfg. Co. and the Boss Rubber Co., has opened an agency for Quaker and Batavia tires at 136 Sixteenth Street, facing Automobile Row, on Broadway.

The Highway Auto Sales Co., a $25,000 corporation, has opened headquarters at 1439 Cleveland Place, Denver, to distribute the Argo and the Crow-Elkhart in Colorado, Wyoming, Utah, New Mexico and Arizona. The officers are S. R. Fitzgarrald, president; N. A. Ballou, vice-president; W. C. Pochon, secretary and treasurer; W. Aldridge, general manager. The new firm will also have a branch office at Salt Lake City.

The Mid-West Auto Sales Co., 1512 Broadway, Denver, distributor for the King, Regal and Jackson, has dropped the last two lines and is handling the King exclusively in the Colorado and Wyoming territory.

The Foster Auto Supply Co., a new Denver concern headed by J. W. Foster, formerly manager of the Denver Auto Goods Co., has opened an accessory store at 138 Sixteenth Street, corner of Broadway. The new firm has contracted for the Colorado territory on the Rayfield carbureter, and has secured the Colorado and Wyoming agency for the Eisemann magneto, Auburn spark plug, Sioux non-leak piston ring and the Kellogg line of pumps.

The Tibbals-Anderson Motor Car Co., formerly the Regal Sales Co., has given up the Denver agency for the Regal and secured the Colorado and Wyoming distributing agency for the Jackson. The new concern will open headquarters at Broadway and Twelfth Avenue.

The Quinn & McGill Motor Supply Co., 1532 Broadway, has taken the Veedol oil agency for Colorado, Wyoming and New Mexico.

Robert Rhea, secretary of the Boss Rubber Co., 1548 Broadway, has resigned his office and left the firm entirely on account of ill health. Arthur Lewis, vice-president, is acting as secretary temporarily.

Cleveland Changes—A number of automobile dealers have moved to new locations in the past week in Cleveland. Within the next few weeks J. H. Greenwald, Chalmers representative, will move to the large building occupied by the Packard Cleveland Co., 1900 East Thirteenth Street.

The Packard Cleveland Co. will then move to its new building, now under construction on Carnegie Avenue, near East Fifty-fifth Street. The Stearns Motor Sales Co. will occupy the former Chalmers quarters at 2106 Euclid Avenue.

The Hamilton Motor Car Co., Chevrolet distributor, is now located at 2336 Euclid Avenue, formerly occupied by the Cuyahoga Sales Co., Chandler distributor. The Cuyahoga Sales Co. has moved to 4400 Euclid Avenue, formerly the Ford home.

The Oldsmobile Cleveland agency, formerly the Windermere Euclid garage, has moved to 2344 Euclid Avenue, the former Chevrolet home. The Windermere Euclid garage will be used as an Olds service station, and the Olds Lakewood service station is soon to be enlarged to give west-siders service.

The Hills Motor Car Co., which handles the Briscoe and the Pathfinder, has moved from 6110 Euclid Avenue to 6010 Euclid Avenue.

The Albaugh Motor Sales Co. has opened a new service station for Metz and Lewis owners.

Stewart Buys Out Partner—J. T. Stewart of the Stewart-Toozer Motor Co., Omaha, Neb., has purchased the interest of George Toozer, and will henceforth conduct the business under the name of the Stewart Motor Car Co. The company will remain in the same quarters, and has taken on the Mitchell car with the Pierce-Arrow, the former of which replaces the Chalmers agency, recently relinquished. F. C. Hill remains with Mr. Stewart as sales manager.

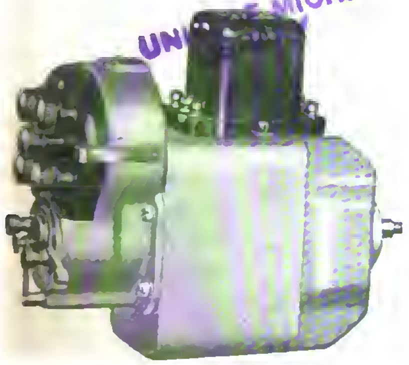
Nikrent Joins Earle C. Anthony—Louis Nikrent, veteran automobile racer, of southern California, has been appointed the technical expert of the Earle C. Anthony, Inc., Los Angeles, Cal., which organization controls the Packard sales throughout southern California and controls the State territory for the Reo.

The Earle C. Anthony, Inc., has added two branches, one in Bakersfield under the management of C. B. Pentoney, and one in San José, under M. N. Brodie. With the addition of these two houses Anthony is represented by branches in six of the largest cities in California.

Michelin Adds—The Michelin Tire Co., Milltown, N. J., will increase its manufacturing building by an addition measuring 53 by 117 ft. The addition is to be one story, brick walls, and a saw tooth roof.

The AUTOMOBILE

Vol. XXXIV, No. 5 NEW YORK, FEBRUARY 3, 1916 Ten cents a copy Three dollars a year



GRAY & DAVIS

Ignition Dynamo

Here is an ignition system of exceptional efficiency. It produces maximum results at **all** speeds.

Very simple in design and construction. Parts immediately accessible.

Quality in material and workmanship exceeds that of any similar device.

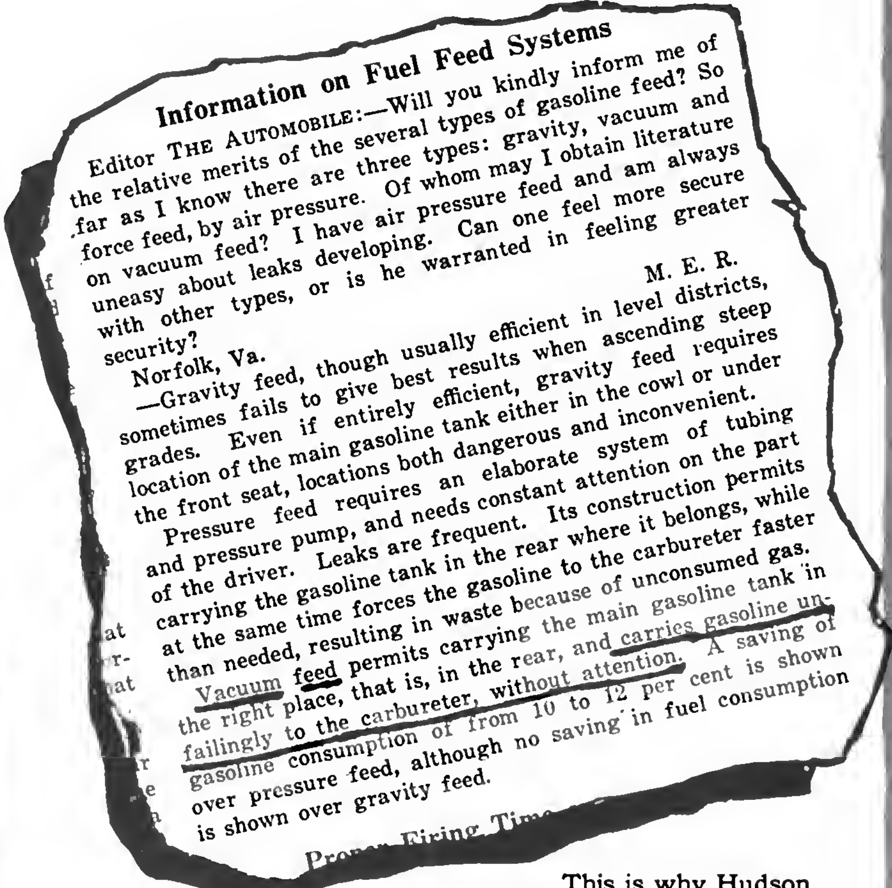
When used with Gray & Davis starting motor, this ignition dynamo offers the utmost in electrical equipment.

Particulars gladly furnished

GRAY & DAVIS, Inc. **BOSTON, MASS**

"Carries Gasoline Unfailingly without Attention"

says "Automobile"



Information on Fuel Feed Systems

Editor THE AUTOMOBILE:—Will you kindly inform me of the relative merits of the several types of gasoline feed? So far as I know there are three types: gravity, vacuum and force feed, by air pressure. Of whom may I obtain literature on vacuum feed? I have air pressure feed and am always uneasy about leaks developing. Can one feel more secure with other types, or is he warranted in feeling greater security?

Norfolk, Va. M. E. R.

—Gravity feed, though usually efficient in level districts, sometimes fails to give best results when ascending steep grades. Even if entirely efficient, gravity feed requires location of the main gasoline tank either in the cowl or under the front seat, locations both dangerous and inconvenient.

Pressure feed requires an elaborate system of tubing and pressure pump, and needs constant attention on the part of the driver. Leaks are frequent. Its construction permits carrying the gasoline tank in the rear where it belongs, while at the same time forces the gasoline to the carbureter faster than needed, resulting in waste because of unconsumed gas.

Vacuum feed permits carrying the main gasoline tank in the right place, that is, in the rear, and carries gasoline unfailingly to the carbureter, without attention. A saving of gasoline consumption of from 10 to 12 per cent is shown over pressure feed, although no saving in fuel consumption is shown over gravity feed.

Pro Firing Tim

Can be installed on any car—old or new

This is why Hudson, Studebaker, Chalmers and Dodge Bros. discarded gasoline tanks in the cowl and pressure feed systems, and are equipping their entire output with Stewart Vacuum System. This is why more than 53% of ALL CARS MANUFACTURED are now equipped regularly with Stewart Vacuum System.

Stewart Vacuum Gasoline System

$10

Any dealer can put this system on any old car and thereby bring it up-to-date. It has put back into the running more old cars than any other feature ever offered the automobile public.

Stewart-Warner Speedometer Corporation, Chicago, U. S. A.

The Automobile

Driver's Lot 99% Discomfort

Although Driver Is Most Often Owner, Comfort of Tonneau Occupants Is More Studied—Entrance and Seating Positions Ill-Considered

By J. Edward Schipper

WHY has the owner-driver been neglected and all the brains and genius of the body builder been concentrated on his wife, children, invited guests and other occupants of the tonneau? Why do we have 21-in. doors on our automobiles and then have to compress our anatomies sufficiently to squeeze our bodies, along with a heavy driving coat, through a space of 7 in. between steering wheel and body combing? Why do we have luxuriously lounging driving seats in which we can repose comfortably, when the car is standing at the curb, but in which we cannot drive for any time without an aching neck due to continuous craning to see the road around, above or below the wide rim of the steering wheel?

There are a multitude of things that go to make a car comfortable, and the hundreds of dollars worth of upholstery placed on a fine body can be set at naught by the neglect of the little details. For several years the exterior appearance of the car has been the study of hundreds of engineers and artists in this country and abroad. Is it not possible that in our race after beauty of outline, we have neglected the, perhaps more important, comfort of the interior?

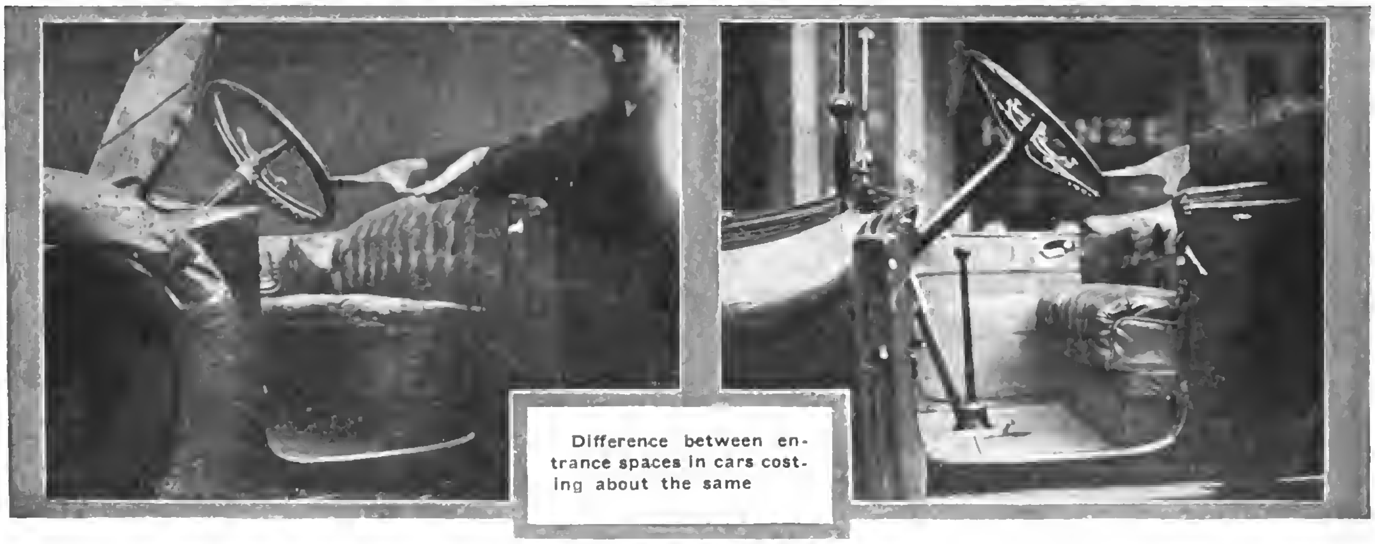
Ninety per cent of the cars in this country are driven by their owners. This means that on all but 10 per cent, the owner of the car is sitting in the driver's seat. This condition is worthy of thought because it means that some of the attention which produces comfort should be focussed on the seat occupied by the man to whom it is most essential that the comforts of motoring should appeal. As the matter stands now he is not only uncomfortable while driving, but on entering or leaving the car, especially with a heavy coat, he is compelled to perform a series of contortions the inconvenience of which is limited only by the narrowness of his waist-line.

The difference between leaning to make a gear change and changing gears in erect position

After having forced an entrance to the car with an effort that is destructive to coat buttons and patience, the next consideration is the sitting posture. On some cars, the driver leans back, on a great majority he sits as erect as the drum major of a crack military band, on a few others he is actually leaning *forward.* The erect position is fair. It is more comfortable to lean back slightly so as to take a little [illegible] strain off the spinal column, b[illegible] it certainly bad to lean forward.

There are many other detail considerations that actually mean comfort or discomfort to the driver, and it must be always remembered that he is generally the man who has bought the car. The position in shifting gears, the amount of reach to get at the emergency lever, the width of the seat, elbow room on the left side in the left-drive car and the position of the feet in driving.

All the trouble is not in the driv-



Difference between entrance spaces in cars costing about the same

er's seat however, although it must be conceded that most of it is. The occupant of the tonneau is quite comfortable in most of the cars, but there are exceptions in cars in which considerable expense has been gone to in providing good upholstery. For instance the camber or curve of the seat in conjunction with the camber of the back rest form a combination which must be just right, or else the occupant of the car, if he is of ordinary stature will quit his seat after the end of a long day's ride with a feeling of relief instead of regret. It is recognized that it is impossible to turn out the bodies of stock cars in the same manner as a tailor fitting suits of clothing, on the other hand, the designer must work to the needs of the person of ordinary stature. Since the tonneau seat must accommodate persons of varying heights and degrees of embonpoint, it is necessary to use care that the camber of seat and back rest do not make the seat uncomfortable to any except the one person that it fits.

To secure accurate data on some of the details which go to make a car comfortable and convenient, a number of measurements have been taken on representative 1916 cars. These measurements have been made for the purpose of bringing comparisons and recommendations down to a definite basis, thereby giving something which may be worked from in designing a body that will eliminate the maximum number of difficulties which are sure to crop up if these little points are neglected.

The measurements taken are shown on the accompanying charts and the tabulations show the actual dimensions of the points noted on the diagrams, in inches. Several inches variation will be noted in several of the columns, and in many of the instances the difference of 1 or 2 in. was the determining factor as to whether the particular point referred to was one of the factors of comfort or discomfort in the design.

Movable Steering Wheel

THE possibility of the non-stationary wheel should be carefully considered. The use of a universal joint at the base of the steering column, a folding wheel that is not clumsy or a telescopic column with adjustable rake are all possibilities, and when any manufacturer puts one of these arrangements or another on his car so that when the driver enters or leaves the car he can push the steering column out of the way, he thereby obtains a talking point which will appeal to every motorist who ever drove his own car.

Squeezing into the driver's seat—This car had more room than most others

Narrow Space Exhausts Patience

The dimension at *A* is the distance from the steering wheel to the seat. It varied all the way from 7 in. to 10 in. on the various cars, and the further away from 7 and the nearer 10 the distance, the more comfortable is the car for a person wearing a heavy coat. There is no advantage in having the steering wheel scraping across the lap of the driver. In entering the car the distance at *A*, is all important. Take the salesman, for instance, who is using the car to make a number of calls necessitating his entering and leaving the car several times during the course of a comparatively short drive; or, take the doctor, or the man on a shopping tour with his wife, or the lady herself; every one of these is compelled to squeeze his or her body and a mass of clothing through a 7-in. space every time he or she leaves or enters the car.

There have been men who have raved against the discomfort of the car under these circumstances, especially in winter when fur coats are the rule. And, since winter driving is becoming the rule and not the exception, this extra thickness of coat must be taken into consideration in determining these dimensions. From the thirty or more cars experimented upon, one could not fail to come to the conclusion that the measurements had been determined in a great many cases by a very thin person clad in very scanty garments.

The distance from the bottom of the steering wheel to the seat should be 9 in., and the driving seat is not convenient and comfortable for even an average person unless it is at least that.

The distance *R*, is closely allied to that at *A*, and is measured from the edge of the door passage to the nearest point on the steering wheel. It is the narrowest part of the entrance through which the

Recommended Dimensions for Comfort

Part of Car	Key Letter on Chart	Dimension in Inches

driver must squeeze in entering the car. Here the distance runs down to 4 in. on one car, 5 in. on another and 7 in. on several. The driver actually has to pass through this space before he can sit down. The car is equipped, taking the 5-in. case as an example, with an 18-in. door. Of what use is the wide door when directly inside it is a passage less than one third the width?

The front door must not only be of good width in order to make it an asset to the car but it must also be far enough back so that when it is open there is no interference with entrance. This can readily be done as shown by car No. 4. In this car the width of the front left door is 20 in., the distance *A*, from steering wheel to seat, is 8 in., which is fair and the important distance *R*, which measures the ability of the driver to enter the car comfortably and quickly, is 11 in. This is good. The *R* dimension is secured by having the door carry away that part of the body which would interfere with entrance, by simply having the side of the seat as part of the door. To put it another way, the position of the door is nearer the back of the car, thus allowing the driver to enter through the center of the door instead of having available only a small part of the entrance space due to the position of the steering wheel.

Easy Steering Position

The *B* distance, which is measured horizontally from the edge of the steering wheel to the back of the front seat should be as large as is consistent with the lines of the car. It is not so vitally important as long as it is within certain figures which can very well be put as 13 and 18 in. With the *A* measurement correct, the driver will normally carry

Dimensions of Rear Compartment on Typical Cars

Car No.	S	T	U	V	W	Remarks
1	32	15	19	46	21	Comfortable, good back rest.
2	31	13½	18	45	25	Seat seems shallow due to excessive camber.
3	34	14	21	46	21	Good. Rear seat flat giving impression of width.
4	32	15	18	46	21	Back seat too erect.
5	27	14	18	42	17	Seat and back rest hard and stiff.
6	31	17	19	48	22	Good slope on rear seat with small hut comfortable camber.
7	34	13	18	47	18	Seat seems shallow due to excessive bulge of hack at too low a point.
8	24	15	22	45	21	Good. Deep seat with high back rest.
9	29	14½	21	46	20	Bad entrance. Door width is 20-in. but passage only 14 in. Seat too erect.
10	36	15½	19	48	20	Good. Soft back with springy upholstery.
11	26	15	20	40	20	Fine deep seat with correct back camber.
12	32	15	18	44	19	Very good. Sloping seat with high back. Could be improved by greater depth of seat.

Of what use is a door that cannot even open? Tire carriers on side

Position taken by driver too low in expensive special body

his hands at about the center of the wheel and with a correct *B* distance he will sit neither too uprightly nor will he recline too much.

The two distances *C* and *D*, that is seat height and reach to shifter lever, should be considered together as they are inter-related to a great degree as regards convenience in changing gears. In nine cars out of every ten, it is necessary to lean into a cramped position to change gears. To reach the change gear lever the driver ought not have to do more than lift his hand. The assembled car is the greatest offender in this detail as the upright shifter lever is allowed to fall where it will, because it is assembled on the coverplate of the unit powerplant gearset. A few considerate manufacturers have taken the trouble to bend the lever so that it is at the driver's hand whenever he wants to use it.

It means much to the life of the car if the gears are changed every time that occasion really demands, and the manufacturers are now endeavoring to educate the public to the use of the gearshift. One of the greatest educators in this respect is to put the gearshifter lever where it can be reached. A bend in the lever will not affect its manipulation in any way and will eliminate the burden of unhandy shifting and be a real asset to the car and driver as regards life of the former and the convenience of the latter. Therefore, the distance *D* should be short, about 6 in. being very good on a car where other details of design allow it. On cars measured, the distance amounted to as much as 14 in. which is double what the maximum should be.

The distance *E* measures the height of the steering wheel center above the floor of the car. It is only important when taken into consideration with the dimensions which govern the height of the driver's head above the floor. The letter *J* indicates whether the driver looks over, under or at the top rim of the steering wheel. The critical line is taken from the eye horizontally. In the tabulation the letter *L* signifies level, meaning that the eye and top of the wheel are on the same level, the letter *O*, means that the eye looks over the wheel and the letter *U* that the driver looks through the wheel.

Must Peer Through Wheel

There are a few people who like the racy appearance of the man who is lying almost flat on his back peering through the interstices of a steering wheel, the majority however, like to have a clear vision of the road and the surrounding country although without the feeling of height and prominence that is imparted by a seat on a municipal sprinkling cart. The happy medium is what is desired and if the line of sight from eye to top of radiator just clears the steering wheel, a very desirable effect is secured.

A very important dimension is denoted by *F*. It measures the distance horizontally from the center of the clutch pedal to the front seat wall. On some cars this distance is too short and the result is that when the leg is drawn back to place the foot upon the clutch pedal, the knee strikes the steering column or the upper part of the leg strikes the steering wheel. Actual sales have been lost because persons, with a slightly longer leg length than usual simply could not drive the car. The adjustable pedal which is increasing in use all the time is the necessary solution. The distance *F* should average about 19 in. with an adjustment of 3½ in. each way.

The height *G*, of the shifter lever is one of the factors which determines whether or not the driver will have to lean every time he makes a shift. It is very interesting to note the differences between the seat height *C*, and the shifter lever height *G*. In the car that had the best shifting arrangement of all those measured, the seat was 13 in. above the floor and the lever center 19, a difference of 6 in. This difference seemed about right to the observer who is of medium build. Other observers checked these claims and substantiated them. The remarks which cover the shifter lever also apply to the emergency lever, although for the latter it may be said it is hardly ever in use. It may be necessary some time to use both the emergency lever and the steering wheel at the same time. This would be almost impossible on a very large proportion of the cars.

In listing the cars that required a lean to make a shift, the symbol *K* is used. Under this heading the words Yes and No signify whether or not it is necessary to make a noticeable lean to shift gears. In many instances where the word No appears, although the driver did not have to bend his body excessively to make the change of gears, the arm had to be uncomfortably stretched. This gives the final check on the other dimensions governing the position of the driver in the seat.

Leaning to Shift Gears

Under the heading *L* will be found a list of cars in which an excessive lean was required to apply the emergency brake. This list is much less severe then it should have been because only very excessive leans are noted as Yes, and any car that allowed the driver to remain in his seated position was classed as No.

The divided seat cars skimp the driver's room in many instances. Where this skimping is felt is in the cramping of the left elbow space. With the high body now in use, it is impossible for the driver to rest his left elbow on the left gunwale without attaining a slouching posture due to a decided list of his body to starboard. A 15-in. seat is not wide enough to give elbow room unless there is a decided flare on the body. With the tendency now to have the body side straight, or even with a slight tumble home, the elbow room is sure to be poor unless the seat is 17 in. or more.

In some respects the divided front seat defeats its own object, unless great care is used in laying out the dimensions. The passage between the seats is supposed to be for the purpose of allowing a passenger to enter or leave the front compartment without stepping outside the car. It would be impossible for a lady clad in heavy garments to squeeze her way through on many of the cars using the divided seat. In fact, many a man would prefer to walk around on the outside. The result is that not only has the driver's seat been cut down to an uncomfortable 15 in. but the object of the sacrifice has not been attained. The suggestion which has been carried out by some, of raising the floor between the two seats, does away with this objection.

Leg-Room in Cloverleaf Types

Speaking of divided front seats brings the cloverleaf roadster immediately to mind. One of the questions which the designers of some of these bodies have failed to ask themselves is, "What is the passenger in the rear seat going to do with that portion of his anatomy which is below his knees?" Sometimes a seat in the theater is very uncomfortable because the aisles are too narrow. Anyone long enough to have suffered through a 2 or 3-hr. performance in a narrow-aisle theater seat will not anxiously look forward to a 7-hr. drive in some of the cloverleaf roadsters, even if the suffering is mitigated to some extent by the privilege of whispering into the ear of the driver without leaving the seat. Knee-room must be allowed and this must be carefully watched in the four-passenger design especially, or the two rear passengers will leave the car as sworn enemies in spite of the efforts of the body builder to secure the effects of sociability or chumminess.

Entering the rear door of the 1916 car, one cannot help but be impressed by the lavish use of space. Perhaps the first thought will be one of wonderment as to what the passengers in the rear seat could possibly have against the driver, that they must be kept as far away from him as possible even if this distance is secured by pushing him close to the cowl board. The distance from the rear seat to the back of the front seat is measured by *S*, in the table. Even on the smaller cars this distance is 27 in. Compare this with 16 in. in the front compartment without even taking into consideration the deeper rear seat. Well may the driver cast his eye longingly behind him and wish that he had an inch or two of the surplus space!

The height *T*, of the rear seat does not vary greatly. On the other hand, the depth *U* varies materially. The seat depth dimension *U*, is quite important. An inch can be perceptibly felt and as long as there is so much room in the tonneau there is no use in sacrificing an inch or two of seat depth when it is really the key to comfort in many instances. If soft upholstery is used a marked camber can be successfully used on the back cushion and the result will be a comfortable seat. On the other hand if the seat is quite solid, it should be flat. An impression of depth is given by flatness. A good deep seat is often destroyed by having the bulge in the back rest too low. This pushes the occupant forward and destroys the effect of the deep seat. It is also the reason for the bolt upright position one is forced to take in so many of our cars whereas a slightly reclining position would be far more comfortable.

No criticism can be made on rear door width. There is plenty of that this year and this has been a most meritorious improvement. In fact in the entire tonneau design each year sees a marked advance in comfort and convenience. The only trouble is that some of this improvement is being secured at the expense of the front compartment and since the man that paid the money for the car is sitting in that compartment compressed between the steering wheel and the seat, it would be well to turn the tide in the other direction for a time.

Conveyor Saves Eleven Minutes Per Assembly

A GOOD illustration of modern speeding up is provided by the aerial conveyor system of the Studebaker Corp., which is used to carry bodies and wheels through the air from one building to another, a distance of 780 ft.

The conveying cables stretch from the third floor of one building to the fourth of another, and the object is to transport the bodies and wheels from manufacturing to assembly departments. Steel trestles support the cables, with the longest span 178 ft. At the terminals it was found necessary to install steel construction in the buildings from the ground up that the weight could be properly supported. The conveyor also crosses a steam railway track, and for safety against damage due to breakdown, a steel overhead bridge protects the cable-way here.

Variations in load are cared for by counterweights that take up any cable slack. The riding cable measures 1¼ in. diameter, and above it is the tow cable, operated by a 10-hp. electric motor.

Twelve Times Quicker Than Trucking

Formerly the bodies and wheels were trucked to the assembling room. This necessitated their being taken down an elevator from the third floor of the finishing department, trucked through a tunnel to the assembly building and then another elevator was used to bring them to the fourth floor. On the average, 12 min. were required for the delivery of a body, with four men to handle it.

Now, two men at each terminus take care of the conveyor and do the loading and unloading. One man can draw a body either onto or off the conveyor car. The best record as yet attained in operating the conveyor has been the delivery of forty-one bodies in 42 min.

As traps catch and release the cable grips without requiring any attention, the operation is merely a matter of attending to the cargo. Wheels are carried in specially-constructed trucks, each made to hold fifteen wheels.

Needless to say the new conveyor scheme, which is only one of many of similar nature now installed in the factories of the concern, is effecting great savings and doing its part to cut down overhead expense.

New aerial conveyor system installed by the Studebaker Corp., Detroit, for the transfer of bodies and wheels from the finishing department to the assembly floor, a distance of 780 feet. Steel cables carry the load, and they are supported by trestles, with the longest span 178 feet

Enlarge French Automobile Factories

Demand for Increased Output of War Munitions Renders Expansion Necessary—All Plants Building Some Cars

By W. F. Bradley

Special Representative of The Automobile with the Allied Armies in France

PARIS, Oct. 15—If it were possible to find a stranger unacquainted with conditions in Europe and to take him on a tour of the automobile factory districts, he would come away with the conviction that the industry is in a most healthy condition. This conclusion would be based on the observation that at every automobile factory of importance building operations are in progress or nearing completion. It would be quicker for me to give a list of the automobile firms which have not, or are not, extending their works, than those having extended their ground area. No attempt will be made to prove that the allied armies have or have not attained their maximum power; but so far as the automobile industry is concerned the output of munitions of war is capable of further development.

Increase Outputs 50 to 100 Per Cent

The organization of the automobile industry of France as an auxiliary of the war department has been complete for a long time, but as the war has lengthened it has become possible to modify plants and extend factories so as to obtain increased outputs varying from 50 to 300 per cent. The machinery in any automobile factory is capable of shell production, but the best results can only be obtained by certain reorganizations and the expansion of certain departments. Until assurances were given that contracts for immense quantities would be placed, factory managements were not inclined to modify their plants and erect new buildings. These assurances have been given, and there are now automobile factories which might have been originally laid out for no other purpose than the production of war material. At the expenditure of considerable capital, plants have been modified so that shells are now produced under conditions which could not be improved upon by the best high-efficiency experts.

At the outset heat-treating and hardening departments were insufficient. Although the plant might be up to date for automobile work, it was not designed for big quantities of one particular type of shell. Some firms might be mentioned which have pulled down their old ovens, intended for various kinds of automobile parts, and replaced them by increased numbers of ovens designed exclusively for handling 75 mm. shells. Some of the smaller factories did not undertake their own hardening and were obliged to send their shells to outside specialists for treatment, with a consequent loss of time in handling and transhipment. In nearly every case this has been remedied.

Forging Plants Were Insufficient

When the automobile industry was taken over by the army there was a considerable shortage of forging plants. During the summer steam hammers were bringing fancy prices and not enough could be found to go round. Instead of shaping the shells under a steam hammer, all the leading factories now have special presses by which it is not only possible to make one-piece shells, but also to avoid all internal machining. Before it was possible to put down the new presses, important foundations had to be dug, in some cases new buildings had to be erected, and the ovens had to be increased in number to keep pace with the presses. In many cases it has been possible to increase output more than 200 per cent by this new plant. In the past it frequently happened that one particular department was so ill-equipped as to hold back the whole factory. As an instance, an automobile factory producing 1500 shells a day had but one machine for testing shells under hydraulic pressure—this pressure being practically 9 tons per sq. in. A lazy or inefficient operator, or a breakdown of this machine, was sufficient to hold back the entire output. These defects have been, or are being very largely remedied, with the result that the output is steadily on the increase, although the number of hands engaged has not appreciably altered.

Shells constitute about 60 per cent of the output of the French automobile factories. Conditions are very varied. In one automobile factory the only automobile parts were in the store room, and the door of this room was locked. In this case the factory had decided to specialize on shells to the exclusion of everything else, and after putting down die presses and erecting a hardening plant, is doing this work in a most efficient manner.

All Factories Building Some Cars

As a general rule, however, all factories are producing some cars, most of them being intended for the army. Although France has placed considerable orders in America, there do not appear to be many cases of touring cars bought abroad. The nearest approach to the touring car hailing from across the water is the Jeffery ¾-ton model, fitted with twin pneumatic tires on rear wheels. Several hundreds of these have gone into service with the ambulance formations. With this exception, all the touring cars for staff officers' use, all the light ambulances, and all the special cars for aviation, wireless telegraphy, searchlights, postal service, etc., are of French construction. The factories most busily occupied on this class of work are Renault, Panhard, Lorraine-Dietrich, Bayard-Clement, Unic, Delaunay-Belleville, Mors, De Dion-Bouton, Berliet and Delahaye. Although these firms are in a position to build cars in really important quantities, they are not supplying much to the public and are shipping next to nothing abroad.

Demand for Aviation Motors

During the last six months the automobile factories have been considerably interested in the production of aviation motors. As the Ministry of War has now allowed it to be announced, France has created since the war an immense fleet of aerial cruisers, both large and small, armed with quick-firing guns and cannons. Most of these aeroplanes have fixed cylinder, water-cooled motors of 150 to 250 hp. One of the biggest of the airships has four Renault twelve-cylinder motors of 250 hp. each, or 1000 hp. in all. The firms which have been most interested in producing the new engines required for the aerial fleet are Renault, Lorraine-Dietrich, Peugeot, Hispano-Suiza, Darracq, De Dion-Bouton, Delaunay-Belleville, and of course the aviation motor firms Clerget, Gnome, and La Rhone. All the motors built by the automobile firms have six, eight or twelve water-cooled cylinders. While the aviation motor firms are continuing their rotary types, they have been obliged, under the call of the war department, to produce fixed cylinder water-cooled types. Clerget has brought out a six with piston valves, and Gnome, who formerly produced nothing but rotaries, is now making a nine fixed-cylinder water-cooled type and a double opposed eight, also with fixed cylinders.

Eight-Cylinder V a Success

One of the most successful of the new aviation motors is an eight-cylinder V-type in aluminum with steel liners screwed into the cylinders. Each set of four cylinders forms a block. Cylinder heads are detachable and carry a pair of valves for each cylinder. An overhead camshaft operates each set of valves direct, there being no intermediate gear whatever. The nearest approach to the elimination of intermediate valve gear has been in the Peugeot racing motors, but on the aviation motor in question even this has been dispensed with, the cam being in direct contact with the valve stem. Another feature of the motor is the elimination of the base chamber as an oil reservoir. All the lubricant is contained in an oil radiator, pumped to the bearings, and then back to the radiator. This is a type of motor conforming to automobile design, and having a direct bearing on automobile production. Yet it has been possible to get the total weight as low as one kilogram (2.2 lb.) per horsepower and to reduce gasoline and oil consumption to 200 grams per horsepower-hour. The best featherweight rotary motors were far from giving such results. It is obvious to anybody who has been able to follow these developments that one outcome of the war will be the production by French manufacturers of six-, eight- and twelve-cylinder automobile engines of a weight hitherto undreamed of. Even though it is not desirable commercially to reduce weight to the low limits pertaining to aviation work, car engines will certainly weigh less after the war than before it.

Big Aviation Sixes

Delaunay-Belleville is producing big six-cylinder aviation motors under the direction of Charles Picker. Picker is a high-efficiency motor expert who before the war specialized in racing motors and produced such motors for various automobile firms. Darracq has secured the designs of the Isotta-Fraschini six-cylinder aviation motor and has laid plans for quantity production. Renault is turning out immense quantities of aeroplane motors, the line comprising his old eight-cylinder, air-cooled model, a six-cylinder, water-cooled, and a twin six, water-cooled. De Dion-Bouton is building an eight, water-cooled, Hispano-Suiza the same general type. Peugeot has made use of racing experience and is producing eights of the same general design as its racing fours. Engineer Henry, who did all the technical work on the Peugeot racing cars, has left his old firm and has obtained a contract for a quantity of eight-cylinder, water-cooled motors of the same design as those he built for the French races, and necessarily having much in common with the Peugeots. Bayard-Clement is interested in six-cylinder airship motors. All the new motors produced by these automobile firms have to undergo a thorough test at the government laboratories. Each engine must run without a stop for 10 to 15 hr., at full power, and attain a certain standard as regards horsepower-weight ratio, fuel consumption, etc. Charles Faroux, who will be remembered in connection with the 1913 race at Indianapolis, is one of the experts at the army laboratory.

Car Plants Help in Aeroplane Work

Not many automobile firms have taken up the production of army aeroplanes. Bayard-Clement is building both airships and aeroplanes, but did so before the war. Darracq has secured the license for the Vickers biplane and is producing Darracq-Vickers aeroplanes for the British army. In a short time this firm will produce aeroplanes complete with motors. There have been so many improvements and so many modifications of type of aeroplanes, that it has hardly been possible for automobile firms with no special experience in aeroplane construction to take up this work. All that the automobile factories can do is to take an accepted design and copy it in every detail. Obviously the aeroplane factories have had to increase their output enormously. In some cases streets have been closed to traffic and built over to provide additional shops, while other firms are obliged to leave their finished machines in the open air, under a military guard, owing to inability to get enough buildings to house them all while waiting delivery. The automobile body shops are able to give considerable help in aeroplane construction, but up to the present have not been called upon to any great extent. While the automobile factories are working at full pressure, the body shops have nothing more important to do than

How a little Zedel wireless telegraphy car came back from the war. The two mechanics had gone for a drink when a shell fell to the right of the car; a second struck to the left and a third squarely on top of the hood, blowing a hole in it, shattering the radiator and breaking the water jacket

Jeffery quad drawing a captured gun into Les Invalides, in Paris

produce ambulance bodies, field kitchens, etc. This class of work does not by any means compensate for their usual high-class business.

Army Takes All Trucks

Although the automobile industry of France is purely an accessory of the war department, it is possible to produce a certain number of cars for private use. These are mostly small cars not required for army purposes. As an instance, Renault is able to furnish a number of his twin-cylinder taxicab chassis which is used for light delivery work. It is absolutely impossible to buy a truck anywhere in France, for, although such firms as Saurer, De Dion-Bouton, Panhard, Bayard-Clement, Lorraine-Dietrich, Delahaye and Aries are producing in fairly large quantities, everything is taken up by the army. As every private truck has been requisitioned for army use, and is either in actual service or held in reserve, business firms find it a difficult matter to make deliveries of general goods. Marseilles, which has a very large trucking business, is one of the towns protesting at being deprived of automobile trucks. Even firms supplying the army have been deprived of their trucks and have to make deliveries by horses and various old types of vehicles.

Demand for Castings and Forgings

Firms endeavoring to produce cars are working under no ordinary difficulties. When the orders are for the army, government assistance is given in securing raw material, and requisitions will be made if material can be found not used for army purposes. The greatest demand is for iron and steel castings, stampings and forgings. One of the leading makers of drop forgings declared recently: "The only question automobile manufacturers ask now is, 'When can you make deliveries?' They never inquire about price; if we can make deliveries, they will foot the bill."

One manufacturer who is trying to do some private business declared that certain forgings for which he paid $16 before the war now cost him $36. Crankshafts for which he paid $23 before the war had gone up to $66. He had been able to place an order in America at $40, but his experience was that this firm did not work to the same fine limits as in Europe, and if there were any defects he would have to bear the loss.

There appears to be comparatively little difficulty in getting aluminum die castings, probably because these are not extensively produced in the invaded area. Steel and iron castings, stampings and forgings, all came from the Ardennes, the North of France and Belgium, all of which is country held by the Germans. Several thousands of dollars' worth of patterns are tied up in the invaded country. New patterns can be obtained readily, but the old patterns will not be available until after the war, if ever. One of the most important forges for automobile parts is the Arbel works, at Douai, which although within sight of the French lines is still in the hands of the enemy. Much ingenuity has had to be displayed in order to use material not usually considered suitable. One firm building a high-class car with axle housings machined from the solid forging found itself for a time unable to secure these forgings, and in consequence made use of a cast-steel housing with a steel tube liner. The same external experience was observed, so that the client was not aware his housing was not machined from the forging.

All automobile supplies have increased in price from 10 to 50 per cent. The fact that half-price has to be deposited with order and remainder on delivery is also an increased cost, for before the war 30 days credit was allowed. The effect of the war is felt in the accessory business, where there is an all around increase. Brass, bronze and iron castings, on which there has been a certain amount of machine work, have increased 40 per cent. Automobile factories have increased the price of spare parts by 30 to 40 per cent, although very few of these spares have been put into stock since the outbreak of war.

With only two or three exceptions, automobile factories are not military establishments, in the same sense as State arsenals, forts, docks, etc. At the same time they are practically all under military control. Broadly, there are three classes of workmen: men under direct military law, who have been ordered to return to the factories; men of the army reserve whom it has been considered desirable to leave at their ordinary employment; and those men who have been rejected as physically unfit or too old for active military service. To this latter class must be added a small number of neutral foreigners. Military inspectors visit the factories daily and exercise direct control over the two classes of military workmen. It is common practice for the inspector to enter and ask for some man whose name is on the military list. He insists on being taken to the place where the man is working; if that man cannot be found, or if he is discovered on private instead of military work, there is trouble in store for somebody. It is only possible to do non-military work with non-military workmen. Although the military men receive their usual pay, live at home and are apparently under the same conditions as in peace times, they are nevertheless subject to stringent supervision. They are not allowed to be absent from work; they are not allowed to change their employment; they are not allowed to work short time, and in many districts there are restrictions as to the sale of liquor to these men.

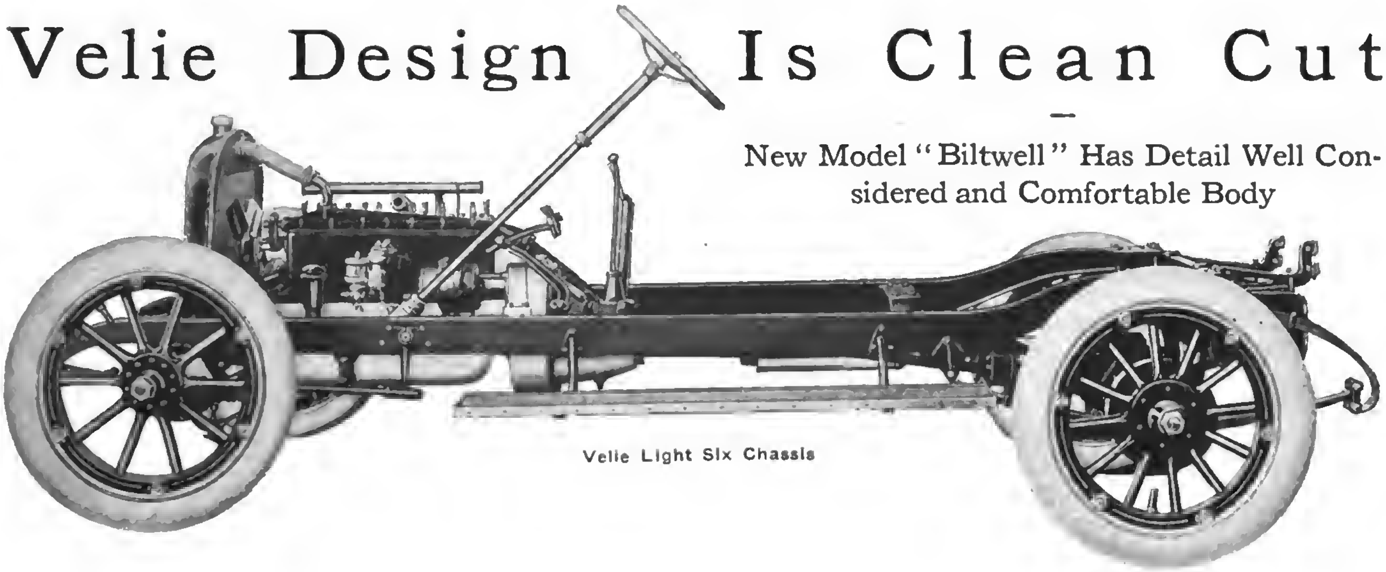
While the military laws cannot be applied to the non-military men, the general effect is to put the entire staff under the same moral obligations. Thus as the military workmen are practically obliged to work 11 hr. a day and six and one-half days per week, the others consider they are under an obligation to do as much. Short time is practically unknown. The strike spirit is entirely absent; if any attempt had to be made to foster a strike it would certainly be suppressed energetically.

Little Change in Tire Factories

There has been comparatively little change in the tire factories. The French factory of the Dunlop company which was closed for a number of months, has been reopened. Michelin is producing both solid and pneumatic tires and also parts of shells in the valve department. The Michelin firm is also interestd in the production of Breguet aeroplanes. The Goodrich factory is working on all kinds of tires, and is supplying both the army and civilians.

Velie Design Is Clean Cut

New Model "Biltwell" Has Detail Well Considered and Comfortable Body



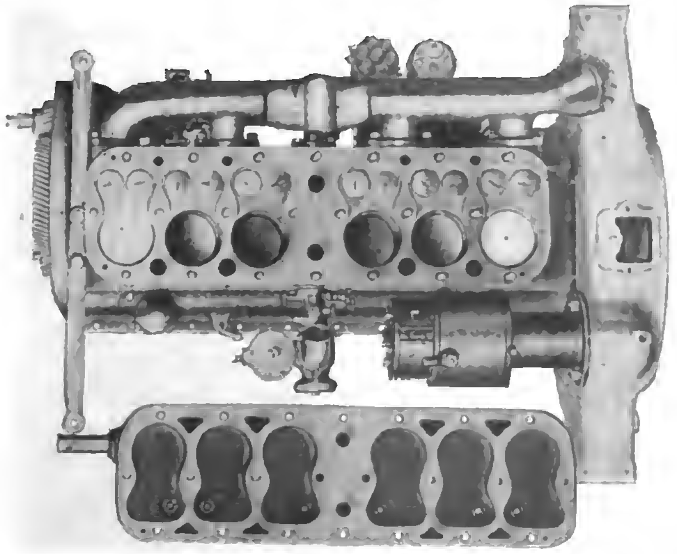
Velie Light Six Chassis

THE Velie Motor Vehicle Co., Moline, Ill., has produced a light six for 1916, selling for $1,065 with five-passenger body, and $1,045 as a roadster, the power plant being the Continental 3¼ by 4½ in. In the layout for the body, the comfort of driver and passengers has been studied, and many little details go to increase the convenience of the former individual. In the chassis, the aim has been to assemble good parts in a way which will enable each to show up to the best advantage, and the frame is designed to support the body at its edges, thus eliminating a certain amount of the ever-present possibility of body squeak after a few months of use.

Uses High-Speed Continental Motor

The engine is a type introduced by Continental last summer, and a sufficient number of the motors are now in use to have earned an excellent reputation. It is the first Continental engine to have the cylinders and upper half of the crankcase in one piece, with the exception of some small fours, and is certainly one of the best appearing jobs the big Detroit plant has ever turned out. The cylinder head is detachable, being held down by twenty-two studs, the nuts being all so accessible that they can be removed very quickly.

High crankshaft speed is aided by the comparatively short stroke, and by the large size of the valves, which are 1⅝ in. diameter in the clear and have a lift of ¼ in., this being sufficient to give a free flow of gas at speeds of 2000 r.p.m. and over. To guard against vibration the crankshaft is 1⅞ in. on the center bearing, the rear and front end bearings being 1/32 larger and 1/32 smaller respectively, to facilitate the reaming operation in assembling the motor for the first time.



Plan of Velie motor with head off

Everything that needs to be handled in a normal way is on the left side of the cylinder block, the carbureter, a Stromberg, bolting direct to the casting and having the oil filler cap close alongside. Just behind the steering gear box, where it is protected and yet easy to reach, is a junction box containing every electrical connection, so that lifting the left side of the hood uncovers everything likely to require inspection. The starting motor also is on this side of the engine, mounted high up where it is safe from inroads of water.

On the right side there is a Remy combined generator and ignition unit of the new, greatly neatened type, this being driven by a universal shaft from the water pump, through a flexible leather coupling. The generator is placed high enough to be accessible, and yet is sufficiently low not to interfere much with the accessibility of the valve stems, when the cover plates are removed. The new Remy generator and igniter has a vertical distributor shaft, or rather a shaft set at a slight angle to the vertical, so as to allow the high tension leads to be carried up well clear of the side of the motor so that interference from the exhaust manifold is prevented.

At the center of the manifold there is a very neat hot-air pocket, made integral with the main manifold casting, the hot-air pipe passing across the cylinders. In the plan view of the motor with the head removed it is easy to see how nicely the various fittings are disposed around it.

Lubrication is on the customary Continental system, there being a small plunger pump which is driven off a cam on the main camshaft. Oil is delivered to the main bearings of the crankshaft and to the timing gears; the large gear is a noiseless material, by the way, and there are also dip troughs for the connecting rods.

Clutch Adjustment Well Cared For

The clutch is a three-plate dry disk having two plates faced with Raybestos gripping a single disk of steel. Pressure from the spring is applied by a system of three levers, and the ball clutch thrust bearing receives its oil supply from the gearset lubricant automatically. Great care has been taken with the clutch adjustment so as to make it as simple and as effective as possible. Firstly, after removing the cover of the bell housing which incloses the clutch, it is only necessary to loosen two cap screws and revolve the toggle carrier in the desired direction and then, when the spring tension is correct, the clutch pedal can be brought back to its original place by a slot adjustment at the foot of the lever. There is also an adjustment on the pedal plate itself and the purpose of providing a setting at both ends of the lever is to enable the pedal to be set to the very best advantage. The adjustment at the upper end is to allow the pedal to be put in the position best suited to the stature of the driver, and this adjustment is not intended to be used in connection with any alteration of the spring pressure, as the more delicate setting at the bottom end of the clutch pedal lever cares for this. Another point about the clutch is that the necessary grip is obtained with a light spring, a pressure of little over 30 lb. being necessary to disengage it.

The three-speed gearbox is of that type in which the countershaft is fixed in the cast-iron outer case, and the countershaft gears revolve upon their shaft, being bushed for this purpose with phosphor bronze. Ball bearings are used upon the main shaft, and the gear ratios provided are 13 to 1 on low, 7.8 to 1 on middle gear and 4.25 to 1 on high. The gear shift is performed by a conventional rocking lever mounted on the gearset cover, but the upper end is brought to a position where it is conveniently within the driver's reach.

Rear end of Velie chassis, showing brake balance gear

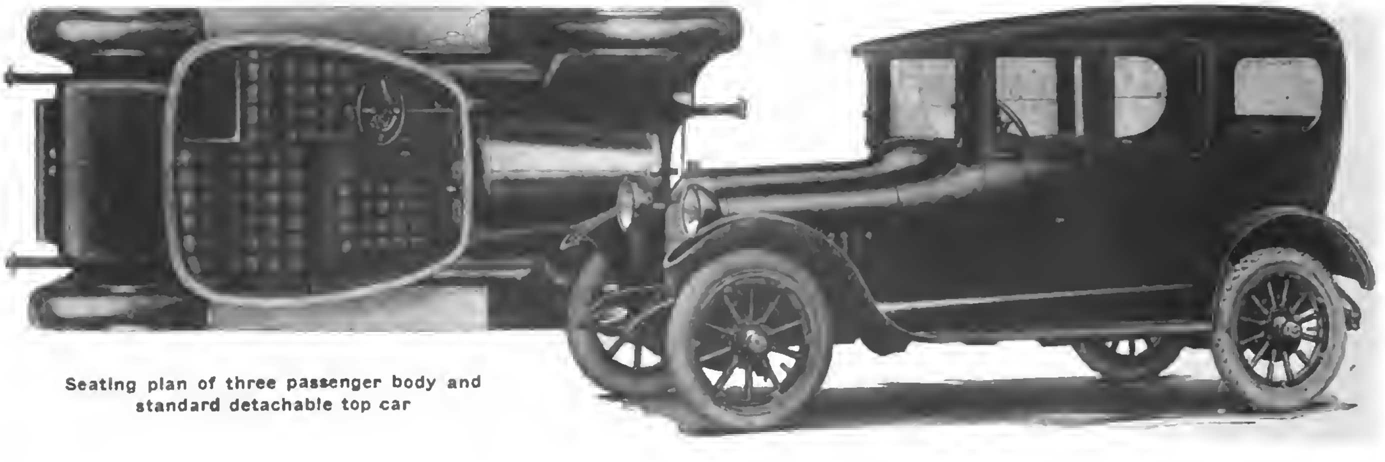
In the rear axle, which is a three-quarter floating Weston-Mott, spiral bevel gears are used, and Hyatt heavy duty roller bearings. Brakes are conventional, the service brake being external, and the bands have the quick-acting thumb nut adjustment introduced by Weston-Mott some months ago. There is a balance beam countershaft for the service and emergency brake, this being made in a unit assembly on a cross rail of the frame, and the pull rods are so arranged that all are straight. Precautions are taken to prevent rattle by attaching coil springs to steady the pull rods, and it is noteworthy that these little springs are stronger than usual and much more neatly applied. It is evident that they are a part of the design and not merely an afterthought.

It was mentioned that special pains were taken in laying out the frame. At first glance this appears to be a simple taper with straight sides wide apart at the rear and close together at the front end, but close examination shows that the frame reaches its full width at the point where the brackets at the front ends of the rear springs are attached. Thence, rearward from this point, the two side rails are parallel, the springs being carried directly beneath them, this removing all twisting stresses from the frame.

Being so wide, the frame is able to support the body in such a way that there is but little overhang at the sides, the floor of the tonneau being almost as wide as the rear seat itself, which has, by the way, ample room for its three passengers. The front compartment is distinctly a good one from the viewpoint of comfort, and the driver can get to his seat without a struggle through the left side door. A very neat radiator shell is used with a bulge in the face of the top water compartment, this giving the car a distinctive front view. Equipment includes double bulb lamps, and all the usual accessories, fuel feed being from a rear tank by Stewart vacuum system. There is a notable absence of points needing lubrication. Of course, the two universals need repacking with grease occasionally and the spring shackles have each their greaser, but the brake connections are mostly supplied with self-lubricating bushings and there are few other parts requiring individual attention. The wheelbase is 115 in., with tires 32 by 4 in.

An Interesting Special Body

Though not a standard factory product, a special body at present in the New York dealer's showroom is worthy of mention, because it includes an extremely neat idea. It is a neat, demountable top design which suits the lines of the Velie touring body excellently, but its special feature is the manner in which the upper half of the door is held. It is well known that when the ordinary side door is opened it falls a little, and all sorts of sliding connections have been devised by detachable top makers to connect the upper and lower portions of the door and yet allow a gap to open between them, the lower half dropping its outer end as it opens and the upper half swinging square to the side. The makers of the special top hit on the happy idea of using a single hinge for the upper portion and putting the hinge pin at an angle, so that the top part of the door drops, when opened, just like the lower half. The two parts operate precisely like a solid door, and yet are more readily divisible than is usually the case with most similar types of body.

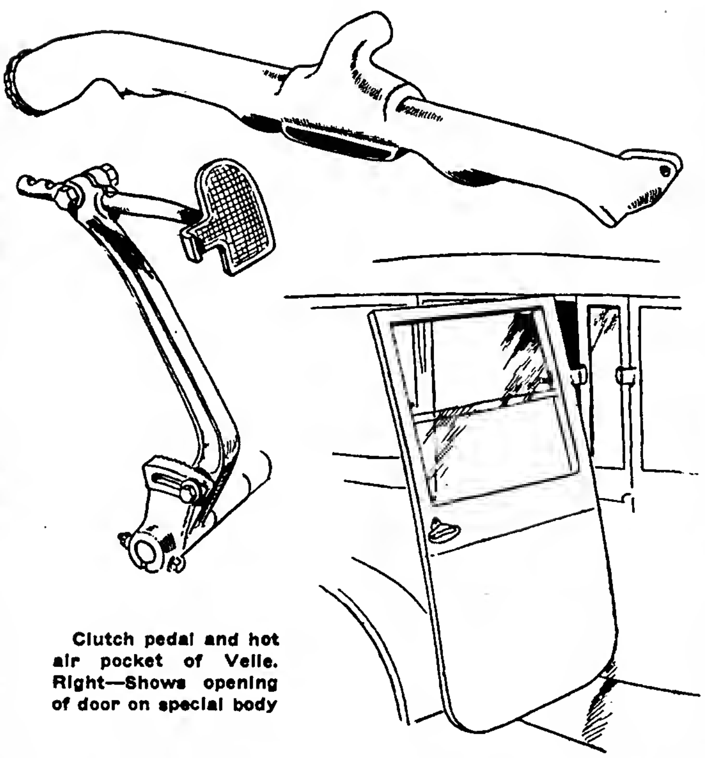


Seating plan of three passenger body and standard detachable top car

In addition to the standard bodies mentioned, the Velie Co. make a touring car with a detachable top, illustrated on the preceding page, and a comfortable car with seating for three passengers, which is likewise shown in the same illustration. These bodies have the same characteristic lines, and the detail in them is just as well cared for as in the other models.

Though they are not supplied as a standard fitting, the Velies that have been supplied with wire wheels disclose the fact that the latter suit the general lines of the car very well. A recently exhibited example of the five-passenger touring car was finished in the regulation dark blue, with a fine white line to outline the upper edge of the body, and white wire wheels. The appearance was extraordinarily smart, though it might be debated upon the score of lasting qualities, it being doubtful whether white is a really good color for wheel painting.

A petty detail that has not so far been mentioned, and yet is characteristic of the care taken with the design as a whole, is the aluminum heel plate which supports the driver's right foot in convenient proximity to the throttle pedal. This accelerator pedal is situated well to the right of the brake pedal, where it can be reached when the leg is fairly well extended, this being thought to be a more comfortable location than the more customary position between the other two pedals, as in this case the leg must be bent a good deal. However, placed so high as it is, the accelerator pedal is only to be reached when the whole of the foot is upon the sloping part of the toe board and there would be a tendency for the foot to slide downward off the accelerator. To prevent this a neat casting of aluminum is attached to the toe board by a couple of screws, having a small curved rest for the heel of the shoe. In this the foot rests easily and the operation of the pedal is ideally easy. The screws that make the attachment can easily be taken out and the heel rest moved to whatever position best suits the driver's convenience in a matter of a few moments.



Clutch pedal and hot air pocket of Velie. Right—Shows opening of door on special body

The Roamer—New Car of Striking Appearance

A NEW car of striking appearance slipped into the Chicago Automobile Show the middle of last week. It is the new Roamer which is being built by the Barley Mfg. Co., Streator, Ill., for the Thomas, Evarts Adams Co., importers of the Lancia car in New York. This company is to be the selling agent for New York and Boston and will also handle all export business on the machine. The Barley company also manufacture the Halladay car, and outside of the territory to be handled by the importers of the Lancia, the Roamer car will carry the name Halladay Special.

The car has been produced primarily with the idea of being marketed to that class of motorists which wants something distinctive in appearance and not too large. The radiator and hood design are copied from the Rolls-Royce and have the characteristic flat-sided appearance that has always helped to distinguish the well-known English product.

The car sells at $1,800, and outside of its somewhat different body lines and general exterior appearance, it is constructed of standard parts, such as Rutenber motor, Grant-Lees gearset, and Lavigne steering gear, Bijur starting and lighting, Bosch magneto ignition, and a Stromberg carbureter are among the important accessories.

In standard form the Roamer is equipped with Houk wire wheels, which add materially to the general appearance. The body is somewhat of the modified boat design with the widest point at about mid-center, and curving and rounding toward the back as well as the cowl. The front seats are individually divided and are almost in the armchair class. A slanting windshield and dome fenders do their part in promoting the good looks of the car. Any color and upholstering can be secured at the list price.

Among the main constructional features of the Roamer chassis are unit power plant, with the gearshift in the center and drive on the left, floating rear axle, a wheelbase of 122 in., three-quarter elliptic rear springs, and 34 by 4 tires. The motor, a standard Rutenber, block-cast, with 3⅛ by 5 dimensions is said to develop 46 hp. on the block.

Cooling is secured positively by a rather large pump, driven by shaft from the front gears. The Bosch magneto ignition is entirely separate from the starting and lighting system which is the Bijur two-unit design with the starting motor connecting by the Bendix shifting mechanism with teeth cut in the flywheel. Throwing on the starting current automatically meshes this Bendix transmission to give driving connection between starting motor and engine, and it is just as quick to release, once the engine is running under its own power.

In connection with the electric system a Willard 6-volt, 100-hr. battery is used, which is of such large capacity as to take care of the trying needs of the electric system adequately. Gasoline is supplied by a 15-gal. tank carried in the rear, from which the fuel is drawn to the carbureter by the Stewart vacuum system.

Throughout the chassis construction back of the motor, F. & S. ball bearings are fitted. The gearset is compact in form, and it as well as the multiple-disk clutch are well supported at the rear of the motor. Three speeds forward are supplied by the use of sturdy gears of 3½ per cent nickel steel.

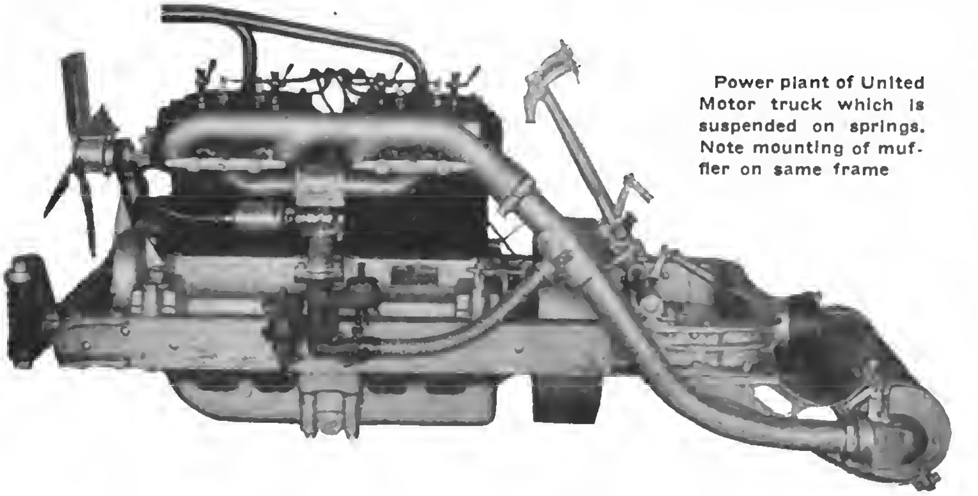
The drive from the motor unit to the rear axle is simplified by the employment of the Hotchkiss system of propulsion whereby both torque members and radius rods are eliminated by giving to the rear springs the added functions of drive and torque reception. The master leaf of each rear spring is made strong enough to do this efficiently, these leaves being 2 in. in width and almost flat.

New Trucks Show Progress

Some Late Models Announced in Past Few Months —Tractors Also Increasing Rapidly in Numbers

THREE new trucks have been brought out by the United States Motor Truck Co., Cincinnati. These are worm-driven models, which adhere to the design of the earlier chain-driven types in a great many ways. The capacities are 2, 3½ and 5 tons, with prices of $2,200, $2,850 and $3,600, respectively, which includes the chassis, driver's seat and standard equipment. The United States concern believes, as many other makers do, that the popularity of the worm-driven type of commercial vehicle is on the ascendancy, and, while it is the intention to make the chain-drive types as well, much attention has been and is to be put on the new models to meet varying conditions of service.

The engines used are of two sizes, of standard truck design. The 2-ton is fitted with a 4⅛ by 5¼, block-cast four-cylinder, L-head type, and the 3½ and 5-ton trucks have a 4½ by 5½ size, with cylinders in pairs. These rate at 27.25 hp. and 32.4 hp., respectively, and develop 40 and 47 hp. at 1500 r.p.m. They are made by Continental.



Power plant of United Motor truck which is suspended on springs. Note mounting of muffler on same frame

Other features include the Cotta type of gearset mounted amidships, this being a design in which the gears are always in mesh, with sliding clutches; Sheldon overhead-worm rear axle; semi-elliptic springs; and Hotchkiss type of drive through the springs.

Although not new to this make of truck, the method of mounting the motor and its allied accessories in a special subframe is none the less interesting. The motor itself is rigidly attached at four points to the subframe, but the latter is, in turn, carried in the main frame at three points to allow for frame weaving without putting any strain on the power unit.

The front end piece of the subframe has an arm extending out to the main frame, and the attachment is through a bracket riveted to the main member. Above and below this bracket is a coil spring that seats on the arm of the yoke end of the subframe member, a pin, running vertically through the yoke arms, the bracket and the coil springs, forming the union of the parts. Thus any vibration upward is taken by the lower coil, and downward vibration and weight through the upper. At the rear, a frame cross member cradles the center of the subframe in a 5-in. ball-and-socket support. This makes the rear of the engine free of the twisting movements of the frame, the front part being taken care of through the coil springs.

Frame Is Wood Filled

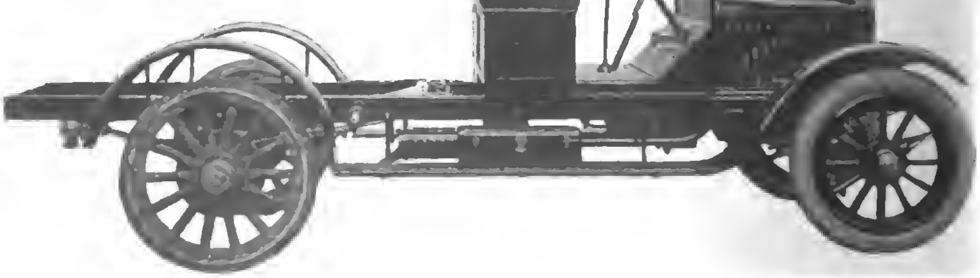
To further strengthen the subframe side rails, the channels are filled in with wood beams flush with the edges, affording a greater factor of safety against distortion at very little added cost or trouble in manufacture. Wood also plays a part in preventing overstraining of the subframe under severe motor twist either from dropping in the clutch suddenly or when the front wheel drops in a hole. Little hardwood bumpers are placed on the rear of the subframe and come in contact with the main frame when the twist gets beyond a certain limit, thus making the main frame assist in carrying the load.

The radiator is mounted in a steel cradle just inside the front frame member, suspended on springs to take care of vibration.

Another good feature which lends itself especially to assembly is the combining of the gasoline tank and control levers into one unit under the driving seat. That is, the brackets which support the tank also form the mountings of the levers and are put together before attachment to the truck frame.

Uses Hotchkiss Drive

The drive shaft between gearset and rear axle is of vanadium steel fitted with a universal at either end. These do not prevent it from being in correct line with the engine shaft except under frame distortion, however. Though unusual



Little Giant three-quarter ton truck which has pneumatic front tires and solids on the rear wheels in truck service, the United States Co. is having great success with the Hotchkiss type of drive, which eliminates any radius rods or torsion arms. The second leaf of each half-elliptic rear spring is made strong enough to take drive and torque, and it is the one that attaches to the frame. The top leaf acts as a rebound absorber, and has a tendency to hold the main leaf against buckling.

Sheldon supplies the over-head worm rear axles used on these trucks. These have substantial malleable housings, and the worm carrier bolts to the top, allowing for quick dismantling of the worm and wheel if necessary. There are also plates at front and rear of the worm carrier to give access to the adjustments of the bearings on either side of the worm. The design is such that there is a straight line drive when under rated load.

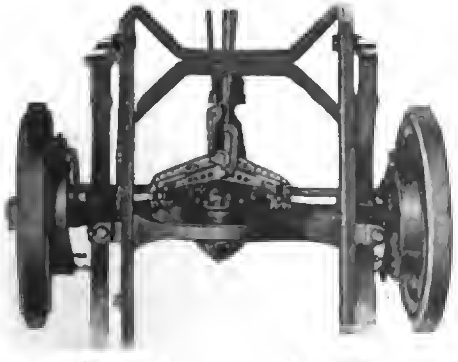
A clever method of equalizing the pull on the two brakes is employed. This is not new in these trucks, but it is worthy of special mention, in that a differential action is attained by the use of a bevel pinion and sector arrangement both on the service and emergency brake rods. A short cast-steel sleeve has an integral, toothed bevel sector. The sleeve carries the end of the shaft loosely, and is provided with a thrust arrangement. Keyed to the shaft is a second sector, so spaced as to match a bevel pinion which is carried on the upper portion of a lever that pivots loosely on the shaft between the sectors. This lever has the regular form of pull rod connection with the control up ahead, and on either end of the shaft assembly is a lever which connects to the brake on that side in the regular way. When force is applied to the brake, it acts upon the lever that carries the bevel pinion with sectors and shaft related, and this continues until resistance is effected by one or both brakes being engaged. But should resistance of one brake take place somewhat ahead of the other, motion through the bevel pinion is caused on the opposite sector until it is also engaged, when the differential movement ceases and equal force is applied to both brakes.

Three Menominee Models

Several features not found in ordinary motor truck construction are prominent in the Menominee, made by the D. F. Poyer Co., Menominee, Mich. Three models, one at $1,125, one at $1,575 and one at $2,240, make up this line, one of 1500-lb. capacity using the spiral bevel drive and the other two, of 2000-lb. and 4000-lb. capacity, employing the worm drive. One of the features is a new type of radiator support, which also acts as a shock absorber. This is a pneumatic device, which, together with the tie rod at the top constitutes a three-point suspension and guards against road shocks, vibrations and warping stresses. This pneumatic rubber sphere offers a cushion and acts as a pivot, incased to protect it against dirt. The headlights also are carried on this shock-absorbing bracket.

Menominee trucks have auxiliary springs, coiled and fitted with special brackets and plunger guides. These springs come into action when the main springs are about to be overtaxed. In addition to this function, the auxiliary springs displace the ordinary rubber bumper and do not allow the load to come in dead contact with the rear axle.

There is an automatic governor driven off the propeller shaft by a friction wheel in contact with the universal flange, acting on the intake manifold or through push rods.



Menominee brake balance gear

Menominee governor drive

All three models have Continental motors, Stromberg carbureters and Bosch magnetos. The Model E has a four-cylinder, 3¾ by 5-in. power plant, the Model FW, 1-ton, a four-cylinder, 3¾ by 5¼-in. and the Model D, 2-ton, a four-cylinder, 4⅛ by 5¼-in. In all models the motor is under the hood. The smallest type uses thermo-syphon cooling and the other two have gear-driven, centrifugal pumps.

The clutch is a Brown-Lipe, multiple-disk, in all three models. The transmission also is Brown-Lipe with three speeds. Timken roller bearings are used on the main shaft and Standard ball bearings on the countershaft. The steering gear is Gemmer, worm and gear type, and the drive is on the left. The rear axle on the Model E is a Timken floating. On the other two models, the Timken-David Brown worm type of rear axle is used.

Uses Radius Rods

The Menominee truck line has another feature not mentioned in the earlier part of this story, it being a tubular type of distance rods designed to relieve the springs of driving stresses. These distance rods are set at an angle so as to maintain uniform distance between the gearset and the rear axle regardless of spring action. This is said practically to eliminate all sliding action of the propeller shafts in the universal. These rods act on swivel attachments on a frame bracket and are provided with adjustments, making it possible to maintain the axle in alignment at all times.

The gear ratio of the Model E is 5 1/13 to 1, the Model FW, 8¾ to 1, and the 2-ton, 9¼ to 1. Semi-elliptic springs both front and rear are found on all models in addition to the auxiliary springs already mentioned. When the emergency is applied the service brake automatically comes in service.

The maximum speed of the Model E is given as 25 m.p.h., of the Model FW, 16 m.p.h., and of the Model D, 14 m.p.h., all these being controlled by the automatic governor. The wheelbases for the Model E, FW, and D are 124, 144 and 144 in. respectively. Tires are solid rubber demountable or pressed on. 34 by 3½ single front and rear on the Model E, 36 by 3½ front and 36 by 5 rear single on the Model FW, and 36 by 4 single front and 36 by 6 single or 36 by 4 dual rear on the Model D. The chassis equipment includes driver's seat, running boards, headlights, Prest-O-Lite tank, two dashlights, tools, and two front and two rear fenders. Special bodies are furnished at various prices for the different types of trucks. The trucks will be painted any color desired without extra charge when ordered with bodies, although the standard colors are yellow running gear and red body.

Gary Is Worm Drive

The Gary Motor Truck Co., Gary, Ind., has in its worm-driven truck line, four models, the Model E, being of 1500-lb. capacity, the Model F, 1-ton; the Model G, 1½-ton and the Model H, 2-ton. All models use four-cylinder, Buda motors, the smaller model having a bore of 3½ in. and a stroke of 5⅛ in., the next, 3¾ by 5⅛, the 1½-ton, 3¾ by 5½, and the 2-ton, 4¼ by 5½. The crankcase is aluminum and the valves are inclosed.

The ignition on all models is by Eisemann magneto, while the carbureter is a new type Stromberg. Lubrication is accomplished by the constant-level, splash system together with a pump. The gearset is of the selective type, offering three speeds forward and one reverse. The clutch is a multiple disk, having facing of Raybestos and running dry. The steel disks are hardened saw steel and all pins are hardened, this construction being designed to eliminate wear as much as possible.

The company advocates the use of the semi-floating type of worm-drive rear axle as against the full-floating for the reason that there are but fourteen parts to the former, whereas the latter has twenty, and thus it is argued that the former is more simple.

Goodyear, type S. V. solid tires are used on all models of the Gary, the ¼-ton using 36 by 3 in front and 36 by 3½, rear; the 1-ton, 36 by 3½ in front and 36 by 4, rear; the 1½-ton, 36 by 3½ in front and 36 by 5, rear; the 2-ton, 36 by 4 in front and 36 by 6 in the rear.

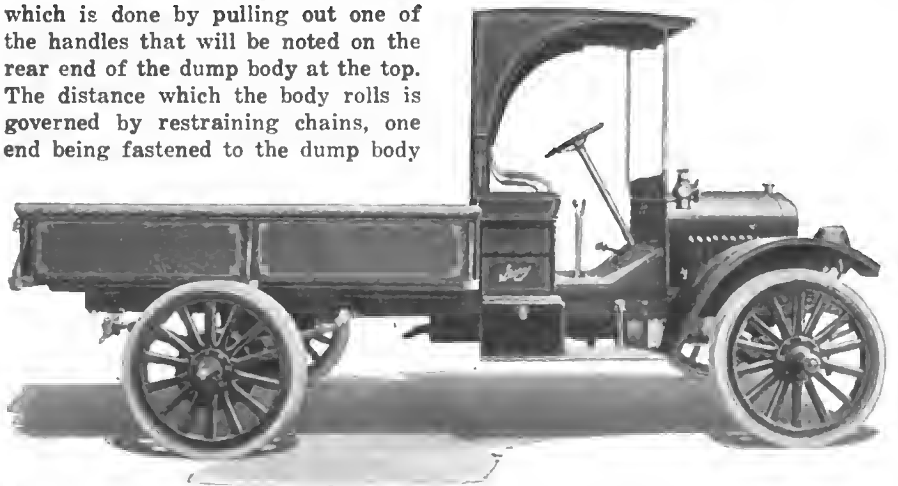
Springs are semi-elliptic, both front and rear and the steering gear is of the worm and split nut type, equipped with an 18-in. wheel on all models. Equipment consists of side oil lamps, tail lamp, horn, jack and tools. Regular express or stake bodies are furnished, although special styles to meet individual requirements are built to order.

These trucks are guaranteed for one year, from the date of delivery to the purchaser, this guarantee being limited to making good, at the factory, any part or parts, that are defective. The company stipulates, however, that the guarantee ceases on any truck on which the governor seals have been broken.

Jeffery Has New Tip Body

The Thos. B. Jeffery Co., Kenosha, Wis. has recently brought out a new two-way side dump hand operated body, to be applied to the Jeffery Quads. The body is secured in position by two catches, one in the front and one in the rear, and an eccentric stop on each side; as well as by three rails on which it rolls in dumping. Each of these rails slopes away from the center line of the chassis to each side and terminates in a hook which acts as one of the final pivoting points when the body is being dumped.

In performing the dumping operation the handle which will be noted in the brace just over the right rear wheel in the illustration is raised, thus releasing the eccentric stop at the upper end of this brace. When the handle is raised clear up this brace may be moved outward which leaves the body free to turn. Next the handle noted in the rear of the body is moved, the action releasing a catch at the top of the inverted V brace, just above the handle, and a similar catch in front to which it is connected by a longitudinal rod.



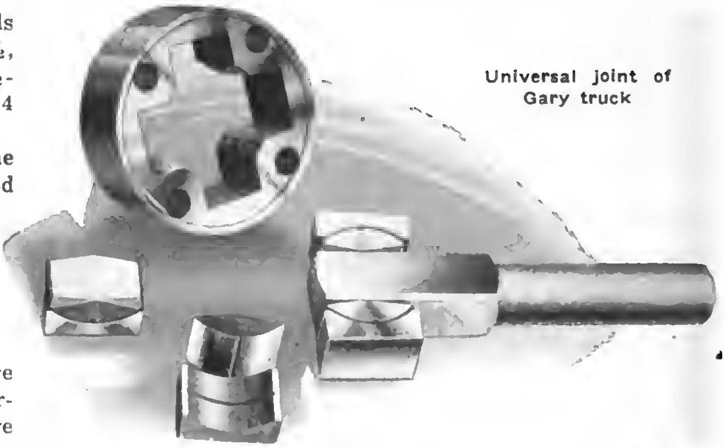
The Gary truck, a light type worm drive

The body now is ready to be dumped which is done by pulling out one of the handles that will be noted on the rear end of the dump body at the top. The distance which the body rolls is governed by restraining chains, one end being fastened to the dump body and the other to the bed of the truck. When empty, the dump body easily turns back into place.

In a series of tests at the Jeffery factory, it is said that an average driver could get down from his seat, dump the load, replace and secure the body and return to his seat in 30 sec.

Chase 1-Ton Worm Drive

The Chase Motor Truck Co., Syracuse, N. Y., has a new 1-ton worm-driven truck known as the model A and listing at $1,650, which employs a four-cylinder, L-head motor with a 3½-in. bore and a 5⅛-in. stroke. The carbureter is a Holley, and the ignition is by Bosch magneto. The gearset is a Brown-Lipe three speed, attached to the flywheel housing. The clutch is a dry-plate and the drive is through a David Brown worm in connection with a Sheldon rear axle.



Universal joint of Gary truck

The steering gear is of the worm and nut type and the wheelbase is 140 in. Front tires are 36 by 3½ single, solid Firestones, and the rear 36 by 5 single-solid. Springs are semi-elliptic front and rear. The tread is 56 in., and the weight on the rear axle is said to be 53 per cent. The fuel tank holds 18 gal., and the oil tank 1¾ gal. The loading space back of the driver's seat is 8½ ft.

Speed is regulated by an automatic governor entirely inclosed and sealed. Electric lighting and starting equipment and rear fenders are furnished but are not included in the price of $1,650. Where the cab and seats are not wanted, a reduction of $40 is made from the list price.

Little Giant Line Includes Light Worm Model

Another light truck with a worm rear axle is the Little Giant made by the Chicago Pneumatic Tool Co., Chicago. Two models, Nos. 15 and 16 of ¾- and 2-ton capacity respectively, have recently been added to the line, which also includes two chain driven models for loads of 1 ton and 1½ tons.

In general the chassis of the Little Giant is on conventional lines, the worm axles being Timken, with the Timken-David Brown worm. Both have Continental motors, the smaller 3½ by 5 in. and the larger 4⅛ by 5¼ in., each having Schebler carbureter, Eisemann magneto ignition and combination splash and force feed oiling, the pumps being of the plunger type driven from the camshaft. Speed is limited by governor to 15 m.p.h. on the large truck and 18½ on the smaller.

Special precautions have been taken to insure the strength of the frames, and the smaller details are all extremely robust in character.

On the smaller car the front tires are

pneumatic 34 by 4½ with single 34 by 3½ solid tires on the rear wheels, but the larger truck has 36 by 4 solid tires in front and dual 36 by 3½ at the rear. Equipment includes every necessary, the smaller car having a 50 amp.-hr. storage battery and lamps which can be used either with an electric bulb or with oil. The prices differ by $1,000 being $1,500 for the ¾-ton and $2,500 for the 2-ton.

Tip body on Jeffery Quad

Simplex Tractor Has Horizontal Motor

Designed to do the work of twelve horses, the Simplex tractor, made by the Simplex Tractor Co., Minneapolis, Minn., is equipped with a four-cylinder double opposed motor having cylinders with a bore of 5 in. and a stroke of 5 in. This motor is designed especially for tractor work developing 70 hp. at 750 r.p.m.

The master gear is of the internal type and is made in sections so that replacements are made easy if some of the teeth should become damaged. This gear attaches to and drives on the wheel rim. Self-lubricating steel pins are found in the master pinion, roller sleeves being substituted for the regulation teeth so that when the gears roll out of mesh friction is reduced. The intermediate gears are machine cut from solid steel and run in oil, which is also true of the transmission gears.

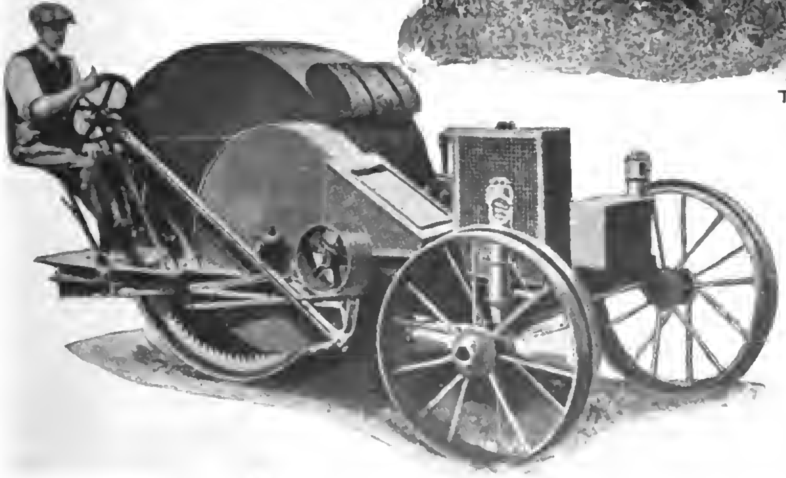
The transmission bearings are Hyatt rollers of the heavy duty type. A Kingston self-adjusting carbureter is used and also a Kingston magneto with impulse starter. Guiding is automatic when plowing, the right front wheel carrying a guiding rim which runs in the furrow and operates as a leader or guide.

On low gear the Simplex has a speed of 1.66 m.p.h., on high 2.32, and on reverse the same as on low gear. The clutch is an expanding two-shoe type lined with asbestos. A cellular radiator together with a 20-in. fan and centrifugal pump furnishes the cooling. The wheelbase is 90 in., and the length over all 12 ft. The turning radius is 17 ft., the weight is 5500 lb., and the price completely equipped for traction or belt work $825. The belt pulley measures 9¾ in. face.

Nilson Tractor Pulls Four Plows

In the Nilson farm machine, made by the Nilson Farm Machine Co., Minneapolis, Minn., and **listing at $1,485, f.o.b. the factory at Waukesha, Wis., one finds a tractor of unusual power, linked with light weight and flexibility. Control is simple, being like that of a truck. It is sold under a guarantee, covering the motor for one year, during which any part or parts of the motor that, under normal use, wear out or show defects will be replaced free of charge. The tractor is guaranteed, if maintained in proper order and operated by a thoroughly competent person, to pull four 14-in. breaking plows, 5 to 7 in. deep in sod or 7 to 9 in. deep in stubble soil; to haul a load of 7 to 8 tons on good roads; to operate a 30-in. separator and equipment, and other stationary equipment for farm work of a similar nature requiring equivalent power, such as seeders, drills, harrows, harvester and ensilage cutters.**

The Nilson farm tractor



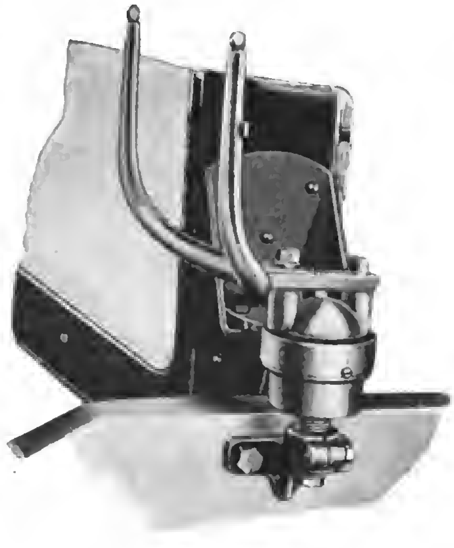
Simplex tractor costing $825

A Waukesha motor is used, having a bore and stroke of 4¾ by 6¾ in., cooled by centrifugal pump, and Perfex radiator, together with a fan. The speed of the engine is regulated by a governor which is adjustable, self-lubricating and non-heating. The engine is rated at 50 to 55 hp. and gives a drawbar pull of 25 hp., while the belt power pull at 800 r.p.m. is 35 hp. The engine is fitted with a Kingston carbureter, although a special combination kerosene and gasoline carbureter is furnished at an extra price. Ignition is by magneto together with a K-W impulse starter.

The gearset runs in oil, being incased in a heavy cast iron, oil- and dust-proof housing. Two speeds forward and one reverse are offered. The speed in **low is approximately 2½ m.p.h. at 800 r.p.m. of the** motor, while the same motor speed gives 6 m.p.h. in high, although both the high and low speeds can be raised or lowered at the option of the driver. Adjustments are possible in the clutch transmission bearings and driving chains to take up wear.

The engine and gearset are each mounted separately on the frame by three-point suspension, and are connected by a universal. Power is delivered to the bull wheel through double chains. The front springs are semi-elliptic and the rear springs are coiled with a special adjustment and equalizing feature. The steering gear is of the worm and sector type and is in an oil-proof case. The weight is approximately 5200 lb. exclusive of extension wheels. These extension wheels just mentioned are 52 in. in diameter and 9 in. wide, and when not ordered included with the tractor a reduction in price is $47.50 for the wheels and $7.50 for one shaft pulley.

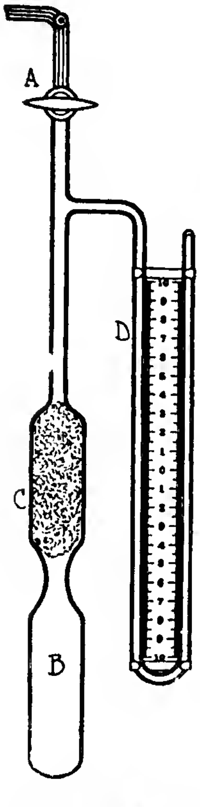
The length over all is 13 ft. 9 in. The tread of the front wheels is 6 ft. 8 in. and the extreme width, 7 ft. 5 in. The height is 5 ft. 9 in., the wheelbase is 8 ft. 4 in., and the turning circle of radius 34 ft. The front wheels are 36 in. in diameter, and the traction or driving wheel 52 in. in diameter with a 23-in. base.



Menominee radiator mounting

Inflammability of Gasoline Vapor

UNDER the file number of technical paper 115, Petroleum Technology 26, the Department of the Interior Bureau of Mines recently issued a booklet entitled Inflammability of Mixtures of Gasoline Vapor and Air, prepared by G. A. Burrell and H. T. Boyd. It presents some valuable data on safety and efficiency in the use of fuels dealing specifically with the inflammable limits of mixtures of gasoline vapor and air and also the method of determining the content of gasoline vapor in such mixtures. These matters are of particular importance in the internal combustion engine and also in ascertaining the risks involved in the storage and use of the volatile hydrocarbon.



The detailed methods of carrying out the experiments can be obtained by applying to the Bureau of Mines, Washington, D. C., for a copy of the bulletin. The general results arrived at are first, a definite method of determining the gasoline vapor in gaseous mixtures and secondly, the limits of inflammability.

The method of determining gasoline vapor in gaseous mixtures is as follows: An apparatus similar to that illustrated is employed. The bulb C contains phosphorous pentoxide for removing water vapor. If the latter were not removed it would also be retained at low temperatures and would subsequently exert pressure when measurement was being made of the pressure exerted by the gasoline vapor.

To start a determination the apparatus is connected to a vacuum pump and its air exhausted. The mixture of gasoline vapor and air is then introduced at atmospheric pressure, the barometer is read, and the two bulbs are immersed in liquid air contained in a Dewar flask. After about 10 min. the air is removed from the apparatus with a vacuum pump. The stopcock on the apparatus is then closed, the liquid air removed, the gasoline allowed to vaporize, and its pressure read on the mercury manometer attached to the apparatus. The ratio of this pressure to the pressure of the atmosphere gives the percentage of gasoline vapor originally in the air.

The tests for the range of explosion were made in a Hempel explosion pipette. Combustion was deemed complete when upon ignition of the mixture, flame filled the vessel as far as could be judged by eye. Measuring the percentage of gasoline vapor in the mixture it was found that no visible results were obtained until somewhere between 1.9 and 2 per cent gasoline vapor. At 1.9 per cent there was no visible result, at 2 per cent there was complete inflammation. Experiments showed that complete inflammation resulted up to as high as 6 per cent after which only incomplete inflammation resulted.

Another set of experiments brought the figure at the lower limit down to 1.5 per cent gasoline vapor. This was for gasoline of 73 deg. Baume. A new set of experiments was made to determine if the low limit for 73 gasoline was different from that of what is known as cleaners' naptha which has a Baume rating of 59 or 60. It was found that complete inflammation started between 1.4 and 1.5 per cent gasoline vapor. Roughly, it may be stated therefore, that a mixture is explosive between the ranges of 1.4 and 6.4 per cent gasoline vapor as far as complete combustion is concerned.

Suit on Fire Policies

In Massachusetts it was recently decided that misdescriptions in applications for fire insurance on automobiles do not necessarily void the policies. Two actions were tried together on three polices of insurance. One policy had been issued in the sum of $1,500 by the Royal Insurance Co. on a Fiat automobile, and the other two had been issued in the sums of $1,800 and $650 respectively, on two Hotchkiss cars by the Columbian Insurance Co.

After the issuance of the policies all three cars were destroyed by fire. When the losses were not paid, suit was brought on the policies and the companies alleged that there had been a misdescription in the year model of the cars in the applications for the policies, though they conceded that the descriptions had been correct as regards the factory numbers of the cars, the types of body, the number of cylinders, the horsepower, etc.

The insurance companies further said that the Fiat car was a 1907 model, and the Hotchkiss cars were 1906 models. An expert who was put on the stand as a witness testified that the cars were all 1908 models; but that did not mean necessarily that they had been manufactured in 1908, as foreign manufacturers did not make yearly models as American manufacturers were accustomed to do, and at that time European cars were designated as 1905-1906, 1906-1907 models of each make.

The court decided therefore that the contract had taken effect, and as neither of the companies had been in the habit of charging greater premiums for 1907 cars than they did for 1908 cars the misdescription was immaterial and the insured was allowed to recover on the policies.—*Locke vs. Royal Ins. Co. and Locke vs. Columbian Ins. Co.*, 107 *Northeastern* (*Massachusetts*) 911.

Trying Direct Fuel Spray

A French Attempt to Use Kerosene By Spraying Into the Cylinders Proved Promising

By W. F. Bradley

SHORTLY before the war some very interesting experiments were carried out in France on a Bellem and Bregeras kerosene or crude oil motor, adapted to a passenger car. This motor has been in use for a certain time in France for big stationary and boat motors. One of the leading French engineering firms has adopted it for kerosene motors to be used as auxiliaries aboard French battleships; it is strictly forbidden to have any gasoline aboard these ships. Certain features of the invention appeared to be prejudicial to the adoption of this motor to private cars and commercial vehicles. The inventor recognized this and modified his design in consequence. For demonstration purposes he converted a Ford motor to his system and ran it on kerosene, starting from cold with no more difficulty than with gasoline. The experiments are one day to be continued with crude oil as fuel, no change whatever being made in the mechanism. To burn crude oil the motor must first be started on kerosene, and as soon as warmed up the crude oil turned on.

Spray Caused by Vacuum

The essential feature of the Bellem system is the spraying of fuel into the cylinder when a partial vacuum has been formed. For this purpose the intake valve is held down during a considerable portion of the induction stroke. During this time the fuel is very finely sprayed into the cylinder, a very small quantity of air being admitted at the same time. By reason of the partial vacuum the fuel is completely vaporized, the cold mist thus formed being as fine as the vapors obtained by heating kerosene. When the mixture is formed, it is diluted with pure air through the ordinary intake valve of the motor. This valve has a rapid opening and does not close until 45 deg. after lower dead center. Compression, firing and exhaust strokes are the same as on any ordinary four-cycle motor.

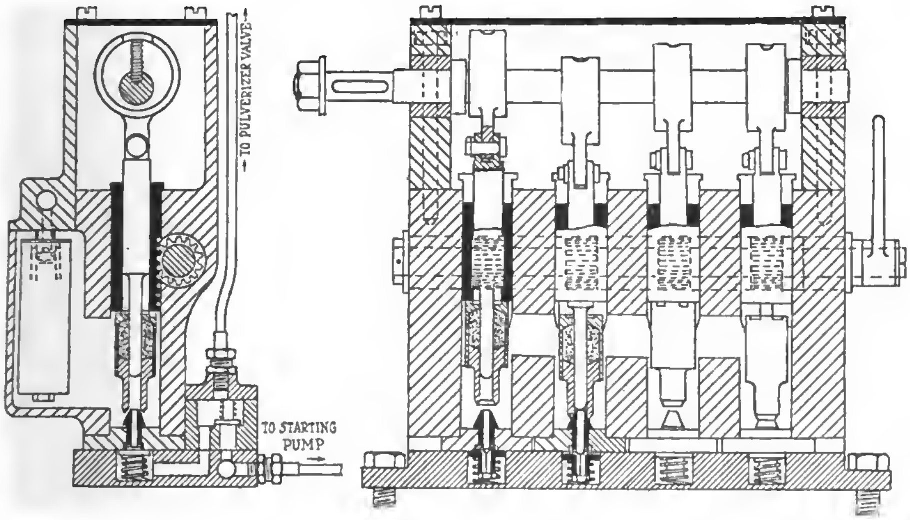


Fig. 2—Fuel pumps of Bellem and Bregeras motor

In the conversion, the Ford was fitted with a new camshaft, on which the intake cams provided for an opening 45 deg. before lower dead center and a closing 45 deg. after lower dead center. The exhaust cam was not changed. A vaporizer valve was mounted in the head of each cylinder by the side of the spark plug. In place of the carbureter, which was completely discarded, there was a metal box about the size of a magneto, within which an eccentric shaft drove the four pump plungers. This shaft operated at half engine speed by means of a chain from the front end of the crankshaft to a countershaft mounted in brackets from the frame member, and by a short chain from the countershaft. Connected up to the intake ports was a pure air manifold. This is nothing more than a brass tube with its ends closed, having a number of slots cut on its circumference. There was a sleeve within the tube capable of a sufficient movement completely to cover or uncover the intake ports, thus varying the amount of air admitted to the cylinders.

The action of the injector is as follows: the pulverizer valve is automatic in action, the fuel arriving through *E*, Fig. 1. On the valve being opened by aspiration, *A* is uncovered, and fuel is sprayed through *B* and *C*. On leaving *C*, it comes in contact with the air, having passed down the valve stem and entered the combustion chamber by *D*. The quantity of fuel sprayed is definitely determined by the pump, and is controllable while the motor is in operation by means of a lever brought up to the steering wheel.

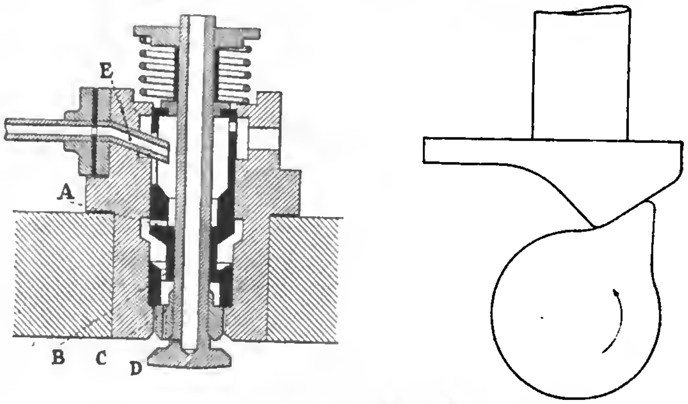

Fig. 1—Details of fuel valve and profile of intake cam

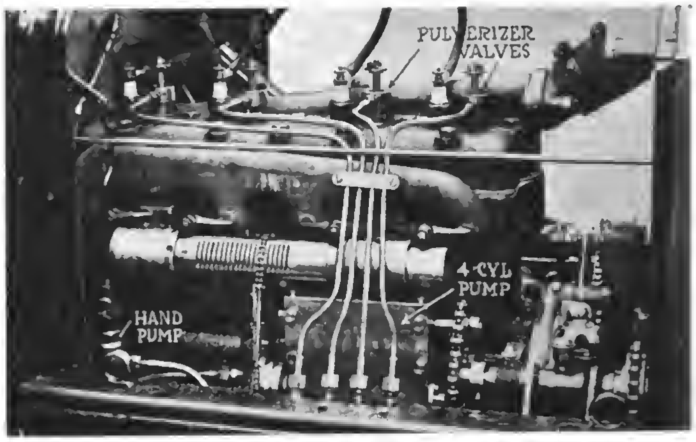
Control Is Effective

The ability to vary the quantity of fuel while the motor is in motion is the most important feature of the pump. The latest type of pump tried is shown in Fig. 2. A constant level is maintained by the usual expedient of a float. The piston, operated by an eccentric, has a prolongation which forms the plunger and passes into the pump cylinder through a stuffing box composed of compressed cork. This material was found to give excellent service. The end of the pump cylinder is conical and abuts against the pump cylinder. It will be seen that the guide can be moved up and down by means of a rack and pinion arrangement, the control for this being brought up to the steering wheel and taking the place of the usual throttle lever.

If the guide is raised by the operation of the steering wheel lever, a certain amount of space will be obtained between the bottom of the guide and the top of the stuffing box. On the upstroke of the plunger, the pump cylinder will first of all be carried along with it by reason of the adhesion of the cork. When the stuffing box abuts against the bottom of the guide, its movement is arrested and during the remainder of the stroke the plunger is moving alone, and drawing in fuel.

It is possible to raise the guide until the play between its extremity and the top of the stuffing box is equal to the stroke of the piston, in which case the cylinder moves up and down with the piston without drawing in or driving out any fuel. Very fine adjustment is obtainable between the guide and the stuffing box, thus giving very minute variations in the amount of fuel fed to the pulverizer valve. On the downstroke of the piston the conical joint is closed and the fuel is forced through the check valve to the pulverizer valve.



Ford motor converted to kerosene system

For starting up there is a small hand pump with control brought through the radiator, as in the case of a carbureter tickler. This allows fuel to be delivered direct to the pulverizer valves.

S. A. E. Appoints New Chairman of Standards Committee

AT the meeting of Council held in Chicago, Jan. 28, A. Ludlow Clayden (Engineering editor of THE AUTOMOBILE) was appointed chairman of the standards committee of the society. Mr. Clayden has been chairman of the foreign co-operation division of the standards committee since its creation early last year.

The resignation of Mr. K. W. Zimmerschied, who has been a most active and able chairman of the standards committee for the past year, was accepted with the deepest regret. Mr. Zimmerschied found that his work as metallurgical expert to the General Motors Co. was growing to such an extent that he could not give the time necessary to the increasing activities of the standardization work.

A. Ludlow Clayden

There is no member of the society who will not regret Mr. Zimmerschied's inability to continue the work which he has handled in so masterly a way; proving a very worthy successor to Henry Souther who was the first chairman of the standards committee, and largely the creator of the standards idea.

Mr. Clayden, who now succeeds Mr. Zimmerschied, was born in England in 1883. His training from the earliest commencement of his education was scientific and mechanical, being completed in the engineering department of Bristol University, England. His business existence commenced in garage and repair work, followed by several factory appointments in Coventry where he gained experience in the early development of both passenger cars and commercial vehicles.

In 1908 he turned to automobile journalism, joining the staff of the publishers of the principal British trade papers, notably *The Autocar*, and two years later founded *The Automobile Engineer.*

In 1911 he made his first visit to this country, and took part in the S. A. E. convention at Dayton, Ohio, that summer, being so impressed with what he heard there and, subsequently, saw in the manufacturing centers, that he set about to organize the visit which representatives of the British Institution of Automobile Engineers paid to the S. A. E. in 1913.

In 1914 he returned to America, and shortly afterwards became connected with the Class Journal Co. in the position which he now holds. He has read several papers before the society, of which he has been a member for six years.

Gasoline High in England

In commenting upon the price of gasoline *The Motor* (England) accuses distillers and importers alike of playing a game entirely to their own ends. In a recent editorial their opinion was expressed as follows:

"We understand that the big importers of motor spirit—other than one company which has not adopted the most recent and otherwise concerted advance of 2 cents per gallon—consider that they have been obliged, by force of circumstances, to follow the course which they have taken. It is represented to us, for example, on behalf of these acting-in-concert importers, that government demands have of late grown to such huge dimensions that it has become almost a matter of kind-heartedness on their part for them to keep up supplies to private car owners, to say nothing of prices.

"We are well aware that the demands of the Mechanical transport columns and units of the army service corps (inclusive of the motor ambulance branch) account for a monthly demand which, while a fluctuating one, is at all times large. We have reason to attach still greater importance to the volume of the demand by the admiralty in connection with the motor-boat patrol.

"We do not see eye-to-eye with price apologists concerning the high rates of freights which rule. It seems to us that the importers of motor spirit are also 'in clover' here, seeing that the freights are to a great extent merely paid out of one pocket into another, having regard to the community of interest which exists in the case of each of the two largest importing companies, between their motor spirit branches and their shipping branches. The net profits promise to be thoroughly well maintained."

The Rostrum

Short Circuit in Ignition Wiring

EDITOR THE AUTOMOBILE:—I have a model 42, 1915 Oldsmobile and at times, turning on the lights stops the engine. Then again, it will be running along all right and the engine stops. Other times, it will run all right for days. I have examined all the wiring and can find nothing loose or dirty or short-circuited. I had the Stewart vacuum gasoline system put on the car and thought perhaps when the engine stopped it was not feeding properly, but on examination, found plenty of gasoline. What do you think is the cause for this and can you give me a remedy?

2—How can I properly install an ammeter on this car?

South Bend, Ind. L. C. M.

—This trouble may either be caused by a poor connection on the ignition system or by a swinging ground somewhere on the circuit that causes the circuit-breaker to trip. It is suggested that you inspect the system and see if the lights go out when the ignition stops. You can test this by trying it on the battery ignition with the lights on.

It is possible that there might be a broken valve spring in the valve leading to the intake manifold on the vacuum system. If this valve spring were broken, occasionally a supply of raw gas would be drawn directly into the intake manifold. This would kill the motor although the gasoline supply in the carbureter would not be seriously affected by the broken spring.

2—In installing an ammeter on this car the instrument should be mounted at a convenient place on the dash and the wire running from the No. 1 post on the switch should be cut and the cut ends of the wire connected to each of the connecting posts on the ammeter.

Connecting Ammeter on 1914 Richmond

Editor THE AUTOMOBILE:—Please give me a drawing for connecting an ammeter to a 1914 Richmond car with Kingston electrical equipment.

Baltic, Ohio. P. S. G.

—The method of attaching an ammeter on a 1914 Richmond car with Kingston equipment is given in Fig. 1. The sketch shows the ammeter connected on the ignition wiring only. It would be operative only when the engine was running on the dry cells and would show the amount of current being drawn from the cells. Fig. 1 also shows a wiring diagram of the Jesco starting and lighting system made by the Jones Electric Starter Co., Chicago, Ill. It is this system which is used for the lighting and starting while the Kingston system is used for ignition. On this system the proper place to put the ammeter would be between the generator and the storage battery, as indicated.

Who Invented the Cord Tire?

Editor THE AUTOMOBILE:—In your article in the November 25 issue of THE AUTOMOBILE on the tire industry and its development in the United States, you make the statement that the Silvertown cord tire is the invention of John Palmer. This is incorrect as it was invented by Thomas Sloper, an Englishman, and the erroneous impression that it is John Palmer's invention springs, no doubt, from the fact that the company in London, England, with whom Mr. Sloper is connected, is known as the Palmer Tyre Co. This concern, although it derived its name, in the early days of the pedal bicycle, from the Palmer cycle tire fabric, owes nothing to John Palmer for the invention and development of the automobile tire made and sold in England and other European countries and known as the Palmer cord tyre which is the parent of the Goodrich Silvertown cord tire now so famous in the United States. That distinction belongs entirely to Thomas Sloper and I think it is due to him that the correction be made.

Akron, Ohio. A. E. C.

—A copy of this letter was submitted to John Palmer who replied as follows:

Editor THE AUTOMOBILE:—I have yours of the 10th inst. and welcome the opportunity for publishing a clear statement of the invention and development of the so-called cord tires, using the phrase as marking in the public mind a type of pneumatic tire in which the carcass consists of two or more independent unconnected layers of cord, insulated from each other by rubber with alternate layers laid at opposing angles without interweaving or other bond as between the two layers and with no consideration given to methods of attaching this structure to the wheel, to processes of manufacture or machinery therefor.

This is the tire as invented by me in 1892, patented in the United States and England in 1893. These English patents

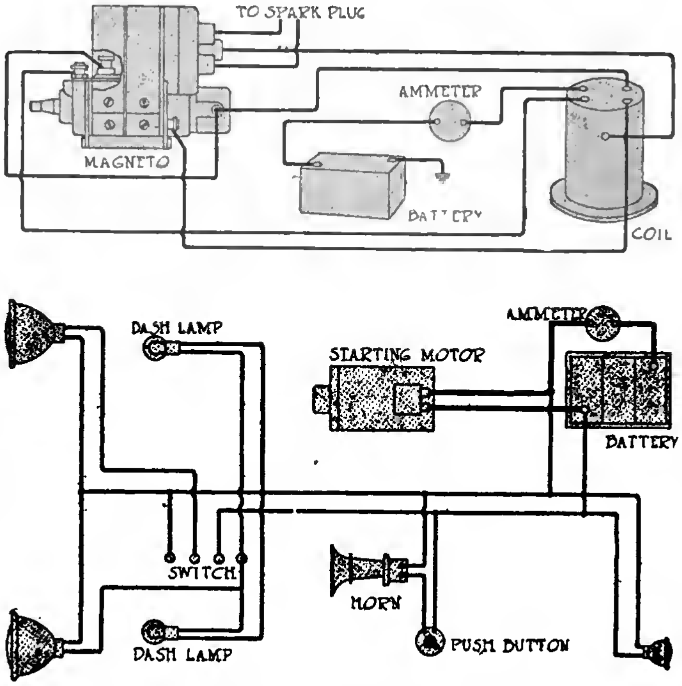


Fig. 1—Wiring diagrams showing connections of ammeters on circuits of the 1914 Richmond. This car has two independent sets of wiring, the Kingston system being used for ignition and the Jesco system for lighting and starting. The upper diagram is for ignition and the lower for lighting and starting

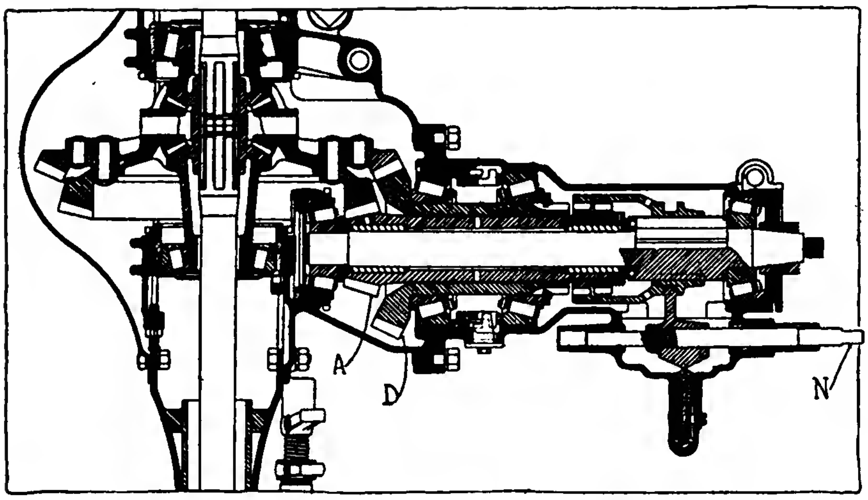

Fig. 2—Sectional view of the Cadillac two-speed rear axle.

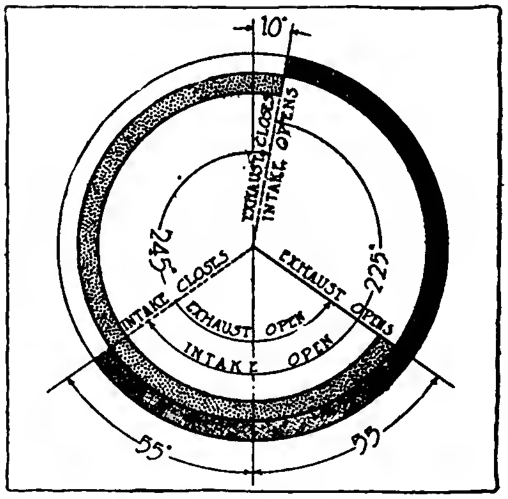

Fig. 3—Timing diagram of Stutz-Wisconsin racing motor

were sold in 1893 to the Palmer Tyre Limited of England, among the stockholders of which was the India Rubber, Gutta Percha and Telegraph Works Co., Ltd., of Silvertown, England, who manufactured the tires.

Thomas Sloper was an employee of this company in the capacity of experimental engineer and as such had much to do with the invention of the processes, devices and machinery that marked the development of the Palmer "cord" tire in England from its original form as a bicycle tire, both of single and double tube type, to what as made to-day for automobiles. I would here point out, however, that in principle and function, the only difference between the original tire and the tire of to-day is one of degree and not of kind.

The first patents covering the broad idea of the tire expired some years ago, and the Sloper patents referred to by your correspondent cover details of construction and machinery as used by the English company.

Concerning the U. S. patents of the original Palmer cord tire, they were purchased by the B. F. Goodrich Co., in 1898. After manufacturing the tire under license and for the Palmer Pneumatic Tire Co., from the beginning, they have manufactured the first Palmer cord tire made, as well as those tires that, carried by me to England in 1893, were used to annex all bicycle racing records from ¼ mile to 24 hr., enabling me to organize a company and sell the patents as previously indicated.

The foregoing is a brief, though accurate statement of the invention and history of the Palmer cord tire. It is not intended to deny credit to Mr. Sloper for anything he did. Much of modern practice and machinery as used by the B. F. Goodrich Co. in the manufacture of the Silvertown tire, is largely his work, as is evidenced by the United States patents, reference marks of which are molded on the tires; they also manufacture the original Palmer tire for bicycles, the first tire made of cord, each cord insulated by rubber and successive layers insulated from each other. In principle, functioning and efficiency, identical with the cord tire of to-day, differing only in those details made necessary by the heavier duty to be performed.

Riverside, Ill. J. F. Palmer.

Jet Velocity Has Indefinite Ratio

Editor The Automobile:—Will you kindly give me what information you can on the following:

Given—the bore, stroke, revolutions per minute for four or more points of an engine, the diameter of intake manifold on the carbureter—

To find—the diameter of jet, area of primary air passing by jet, amount of gas drawn out of jet by air with given velocity; the velocity of air passing jet. If venturi tube is used for primary air which increases velocity of air at jet 2:1 how much more gas drawn out—

To find—is amount of gas drawn out proportional to velocity of air past jet? If so, what constant is used?

U. of M. Ann Arbor, Mich. F. B. A. McD.

—Although from the data supplied the volume and velocity of the primary air can readily be determined theoretically, no practical calculation can be made due to the variation in volumetric efficiency of the motor and also due to the influence of the shape of the venturi and the shape of the jet. The results of practice are those obtained more by experimentation than by calculation. The amount of gasoline drawn through the jet does not bear a constant ratio to the velocity of air past the jet.

Two-Speed Axle Provided Two Ratios

Editor The Automobile:—Please explain the two-speed rear axle used on the Cadillac or any other car. Was it not a good thing? How much weight would it add to 20- or 25-hp. engine? Could it be applied to a Ford? Is it being used now and giving good satisfaction? Is it very expensive to build?

Fort Kent, Me. J. O. M.

—A diagram of the Cadillac two-speed rear axle as used on the stock models in 1915 is shown in Fig. 2. As a study of the axle will disclose, there were two sets of pinion and crown gear units, one pinion being at *D* and the other at *A*. Either of these could be thrown into engagement by means of the sliding jaw-clutch mechanism operated through the rod *N*.

Regarding whether or not it was a good appliance for the car is a matter of personal opinion, but it is greatly to be doubted if its use would be recommended on a small car such as the Ford. There is only one car at present using the two-speed rear axle and that is the Austin on which it is giving good satisfaction.

The expense of building would depend entirely on the quantity of production. If turned out in large quantities it would not be expensive, but for a few individual jobs it would be. The two-speed rear axle is covered very thoroughly by patents owned by the Austin company.

Timing of High-Speed Racing Motors

Editor The Automobile:—Please furnish us information on the timing of the high-speed motors such as the Stutz-Wisconsin, Peugeot, Mercer, Duesenberg and Maxwell.

Harrisburg, Pa. H. E. G.

—The timing on some of the motors you mention is kept a secret. On the Duesenberg motor the timing is as follows:

Exhaust valve opens 46 deg. before bottom dead center.
Exhaust valve closes 8 deg. after top center.
Intake opens 4 deg. after top center.
Intake closes 42 deg. after bottom center.
This is for the eight-valve motor.

On the racing Maxwell the intake opens at top dead center and closes 32 deg. past lower dead center. The exhaust opens 69 deg. before lower center and closes 13 deg. 45 min. after top dead center.

The timing of the Stutz-Wisconsin motor type JR 5 1/10 by 5½ is shown in the diagram given in Fig. 3.

Removing Clutch Spring of 1912 Westcott

Editor THE AUTOMOBILE:—Will you kindly show and explain by drawing how I could remove a clutch spring on a 1912 Westcott car, model R. The clutch has been slipping for some time, especially when I accelerate the motor while running on high speed. The leather was removed last spring and kept in good condition and I feel certain the difficulty is in a weak spring.

Buffalo, N. Y. K. J. S.

—To remove the clutch spring it is first necessary to remove the front universal joint and also the clutch cone sleeve. Then, by loosening the lock nut on the spindle or the shaft that goes through the clutch spring, access will be had to the large retaining nut that is also on the spindle of the shaft and controls the tension of the spring. By backing this large retaining nut off, the spring will gradually loosen.

It will be necessary to exercise a little care in this operation, as it is quite likely that due to the tension on the spring it might fly off and result in injury to the mechanic. When once the spring is removed, it is an easy matter to accomplish the taking out of the clutch proper.

The trouble you are having might very well be taken care of by simply increasing the tension on the spring through tightening the large retaining nut. It might also be well to note that the Westcott company figures the length of the clutch spring when compressed to be 2¼ in. from the inside flange of the clutch. This, of course, is measured less the distance of the face of the clutch outside of the edge of the flywheel.

Installing Dry Batteries on Detroiter 1914

Editor THE AUTOMOBILE:—I have a Detroiter, 1914 model, with an electric starter, but want to put dry cell batteries on for starting. Kindly give me a descriptive picture of the wiring and the necessary equipment needed for this job? Would like to take the starter off as it is always out of order.

Guilford, Mo. J. E. B.

—For your guidance in taking care of the electric system on your Detroiter, 1914 model, it is recommended that you secure a Remy instruction book from the Detroiter company.

It will not be necessary for you to make many changes in applying the set of dry batteries to the system. There is an extra pole on the ignition switch which takes care of the wiring of dry batteries. The system employed is low-tension and the circuit is opened by the use of the relay. As soon as the current is built up by the generator the relay is closed and the ignition is no longer taken from the battery but directly from the generator.

It is not evident why dry batteries should be installed, as it is hardly possible that the storage battery becomes so low that it cannot be used for ignition.

Switches Had No Idle Position

Editor THE AUTOMOBILE:—Why is the positive shunt lead carried all the way to the battery instead of grounded on the Bijur system on 1915 Scripps-Booth?

Newark, N. J. R. J.

—The wiring diagram for the Scripps-Booth is shown in Fig. 4—below—for all cars numbered from 1 to 1100, while above is shown the wiring diagram for cars numbered above 1100.

Referring to Fig. 4—below—the shunt lead is carried to the positive battery terminal instead of being grounded direct, so that removing the storage battery opens the shunt field circuit of the motor generator, which prevents any damage to this machine in case the gas motor is operated without the battery.

The starting switch, above, Fig. 4, has three positions, On, Off and Idle, and the field circuit of the motor generator is broken through this switch when the switch is moved to the Idle position, which would be the normal operating position when running the car without the storage battery.

Switches on cars from 1 to 1100 inclusive were not provided with the Idle position, hence the necessity of carrying the shunt field lead back to the positive of the storage battery.

Specific Gravity of Battery Electrolyte

Editor THE AUTOMOBILE:—If the specific gravity of the electrolyte in a storage battery has a reading of 1.250 at a temperature of 70 deg. Fahr., what should the reading be at a temperature of 60 deg., 50 deg. or 20 deg., assuming that the battery is in the same condition?

Stroudsburg, Pa. M. F. H.

—If the electrolyte has a specific gravity of 1.250 at 70 deg. Fahr. the reading will be 1.254 at 60 deg., 1.258 at 50 deg. and 1.270 at 20 deg. There is a variation of 0.0004 for each degree of temperature.

Outer Wheel Exerts Driving Power

Editor THE AUTOMOBILE:—How is the power divided on the rear wheels of an automobile going around turns at right angles? Is the power equal on both wheels or is there more on one wheel than on the other?

Lorain, Ohio. W. GEM.

—In turning a curve at right angles the power is exerted by the outside wheel while the inside wheel simply acts as a pivot point.

The FORVM

CHAS. E. DURYEA DISCUSSES POINTS IN STEERING GEAR LAYOUT—THINKS TILTED PIVOT IS A REAL ADVANTAGE—CASTOR ACTION IMPORTANT

Improving the Car's Steering

By Chas. E. Duryea

PHILADELPHIA, PA.—Editor THE AUTOMOBILE:—I trust A. L. Clayden will permit me to call attention to some errors in his article on steering in THE AUTOMOBILE for Sept. 2. This subject has been badly neglected by makers and yet is of vital importance to drivers if we may believe the published reports of accidents due to the steering going wrong. Good steerings can be had so easily and, as Mr. Clayden says, are so superior that any one who has had one will not be satisfied with any other.

With regard to Fig. 1, Mr. Clayden leaves the reader with the impression that faulty steering angles may cause the rear wheels to skid; or one of them to do so. This seems incorrect. The rears act just as the wheels of a hand cart and no manipulation of the front end of a hand cart will cause the rears to skid unless it be swung bodily to one side, a condition that cannot exist if one front wheel still rolls, as he rightly says it will. In other words the angle error of the front wheels gives rise to a powerful force parallel to the front axle but so nearly equal on both front wheels that the effect on the rears is negligible and skidding of the rears would not relieve the fronts for it would not change their angles.

Proper Castor Effect

The most important part about steering is the proper castor effect. The best steerings get the pivot line into the wheel contact line or near to it and so force the pivot to take the thrust and thus relieve the steering parts and the operator. Steering would be much safer if all cars were thus equipped and we should keep hammering at the matter till they are. While inclining the wheels outward is not the proper solution, as Mr. Clayden correctly points out, it is so much better than nothing that it is advised next to the proper arrangement. A trial will demonstrate this in spite of Mr. Clayden's mathematical demonstration.

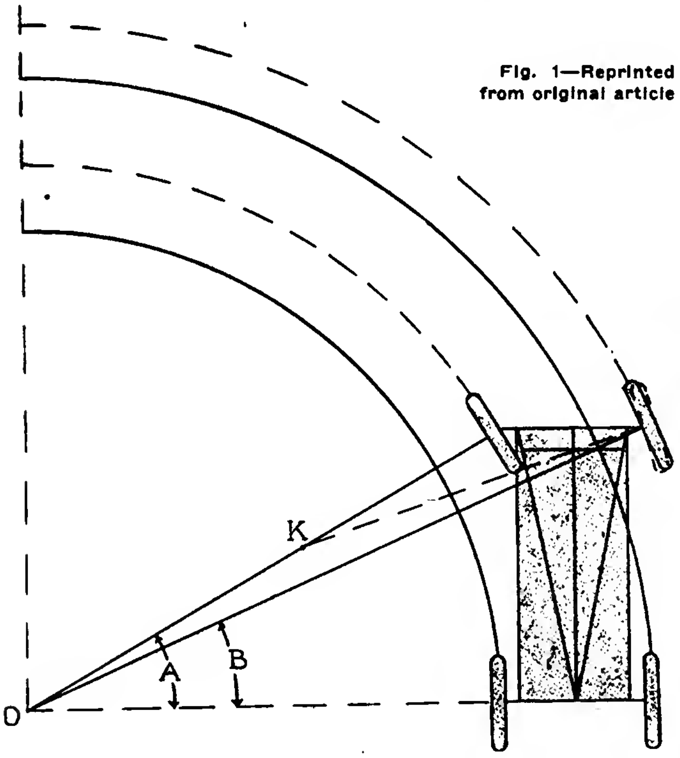

Fig. 1—Reprinted from original article

If the Tie Rod Breaks

He seems to be wrong in assuming that the driving thrust is applied "at the center of the wheel in the plane of the wheel." It is not necessarily so. The rear wheels push the front axle. If the tie bar holds, the front spindles are kept from turning by it and pushed by the front axle in the usual arrangement but what happens if the tie bar should break? With the usual arrangement the front wheel that is not connected also to the drag link will swing around across the car and an accident follows. If Mr. Clayden's arguments are correct this is what will happen with any arrangement except the one which has the pivot inside the hub and in the wheel plane. But the facts are not so. Mr. Clayden has driven Duryea cars and surely knows that they will run over a brick with the driver's hands off the control just as will a bicycle and everybody knows that a bicycle, having the pivot in the wheel plane, cannot be beaten for steering. With the inclined pivot shown in Fig. 10 the tie bar may be disconnected and the wheel will continue its course. This has been demonstrated many times and can be again when wanted. Mr. Clayden must therefore revise his explanation.

By inclining the pivot line slightly more so as to cross the wheel plane above the contact point we can make the wheel pivot resist such strains as that of running over a brick.

But there is another essential to good steering. Putting the pivot line into the contact line or near it is not enough. The castor effect must be introduced. Everybody knows the ordinary furniture castor. Its pivot and wheel plane are both vertical. Its essential feature is having the pivot line ahead of the wheel contact on the ground. It so happens

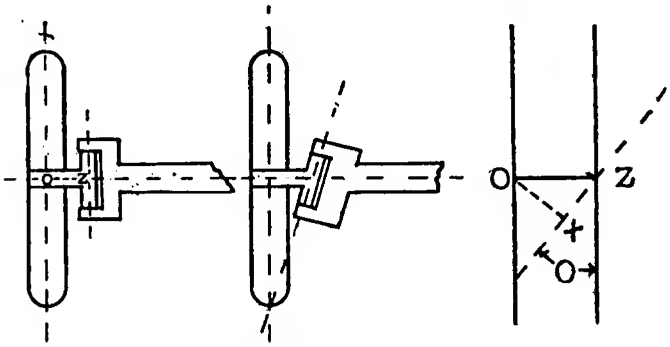

Fig. 10—Diagram of inclined pivot

that its pivot is in the plane of the wheel but this is not essential as Mr. Clayden thinks and states.

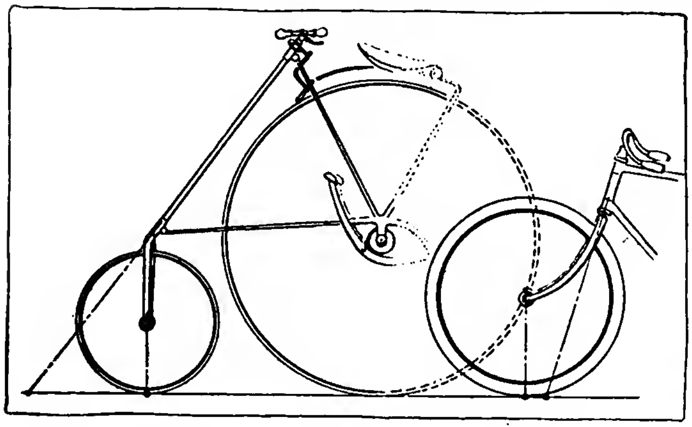
Push—Not Weight

The thing that makes a furniture castor operate is push; not weight as Mr. Clayden states. Lean a bicycle and the weight of the wheel in front of the pivot being greater than that behind the pivot, as seen in Fig. 13, makes the wheel turn to the lower side. But propel or push the bicycle and its steering wheel at once straightens up against the weight action and it travels in the line of the push. This is true castor action and just what is desired in an automobile. Why makers are so slow about incorporating it is one of the things no man can find out. Mr. Clayden will reply that he means vehicle weight and not wheel weight as the operating force. So I will be obliged to ask him to refer to the Star or Eagle cycles in which there is no question about turning the wheel lowering the weight. See the accompanying sketch. They were the best steerers ever made. When they were leaned it was the weight of the machine added to the weight of the wheel that caused the wheel to turn to one side. In some cycles there is a slight raising of the frame when the wheel is turned from its plane but this is so slight as to be negligible. It can be very much increased, however, by setting the steering pivot behind the contact point and if Mr. Clayden is correct this should render the steering more certain. It does just the reverse and most cycle riders have difficulty with such a device.

Weight Factor Unimportant

In most automobiles the load is carried by the top end of the forked front axle which is higher than the wheel axis and so the highest position of the load is when the contact is at the lower end of a line through the axis and carrying point. Most steering pivots are so nearly vertical that the deviation from this highest point is very slight. As a matter of fact, in automobile steering the weight has very little to do with the wheel position for one wheel turns one way and the other turns the other way and what one wheel loses by lifting the load the other gains by lowering it.

The castor effect is the only one responsible for the self-steering action. And this castor effect can be practically as well obtained by inclining the pivots as by more expensive methods. The inclined pivot costs no more than a vertical one and makers will use it if buyers demand it.—Chas. E. Duryea, Consulting Engineer.



Above—Star bicycle, showing how pronounced castor effect makes for good steering. Also—Badly designed safety bicycle where the prolongation of the steering pivot falls behind the wheel's point of contact with the ground. Below—Figs. 12, 13 and 14, referred to by Mr. Duryea

Mulholland Makes De Luxe Ambulance

WHAT has been described as the ambulance de luxe was shipped, recently, by the Mulholland Body Co., Dunkirk, N. Y., in connection with a Cadillac eight chassis, to the Houston Motor Car Co. of Houston, Tex. This car is probably one of the most completely equipped ambulances on the market, having a spring cot, seats for the doctor and nurse, compartments for stretchers, medicine cabinet and pulmotor. The car contains a heater operating from the exhaust, speaking tubes, electric fans, electric dome lights, sanitary waste container, hot and cold running water with washstand, water cooler, ventilators, silk curtains, plate glass sashless windows running in velvet covered grooves, and the body itself is designed with rounded corners within to avoid the necessity of cleaning dust.

The ambulance body has an ash frame with the paneling interior and exterior of Vehisote. The cowl and fore doors are of sheet steel and here also the corners are all rounded. The stretcher compartment measures 7½ by 8 by 46 in. It contains one stretcher and in order that this may be accommodated it is hinged in the center, allowing it to be doubled.

The medicine cabinet is a drawer beneath the spring cot and measures 8 in. by 9¾ in. by 25 in. The pulmotor is also in a drawer under the spring cot in a compartment which is adaptable to the pulmotor as regards size.

The car is heated by the Dunco heater made by the Dunkirk Corp. of this city. It is a hot air type with the register located in the front of the car and the heat is secured by placing a hot air jacket around one of the mufflers, this method providing ample heat for the purpose. The electric fan is located in front of the car directly in front of the washstand and the current for running it is secured from the storage battery which is part of the standard equipment.

In order to secure hot and cold water for the wash basin, two tanks were built under the driver's seat and into these tanks the regular air line was tapped. This is the line which provides the pressure on a gasoline tank. The hot water is secured by placing a copper waterjacket around one muffler and in this way with a two-way faucet arrangement either hot or cold water may be obtained at 2-lb. pressure.

Book on Lathes

THE South Bend Lathe Works, South Bend, Ind., has issued a useful booklet dealing with the practical problems of lathe operation in a practical manner. Not only is there a great deal of information given on the actual working of the machine, but its setting up, shop location, power drive and countershaft installation are covered in detail. Screw-cutting, taper turning, keyway and other special work, the use of the compound gearing, tool grinding, drilling, valve work, boring and tool tempering are a few of the many subjects treated. The booklet is of the genuinely helpful kind, and there are not a few things in it that may be of use to the old lathe hand.

The History of the American Automobile Industry—15

Early Development of the Gasoline Engine—Basic Ideas in Hot Air Engines Invented Centuries Ago —Tracing Their Evolution From the Days of Hero

By David Beecroft

THE previous chapters of this history have largely had to do with the development of steam vehicles, dating from the earliest times and including those developed up to 1890. Beginning with 1898, there was a very great development in steam vehicles which continued for eight or nine years, and which has continued itself up to the present in the Stanley steam car. Before taking up the history of this recent rise in steam, in which more than fifty different manufacturers were producing vehicles at the same time, it has been deemed better to leave this for later chapters, and to refer now to the early development of the gasoline engine as we know it to-day.

Gas Engine's Development

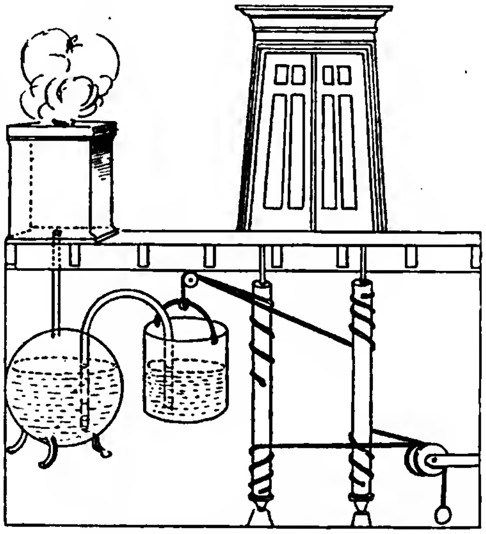
It is practically as difficult to trace the development of the modern internal combustion engine, in fact more difficult, than to follow the thread of steam evolution through the past centuries. The modern internal combustion engine, which we know to-day as the gasoline engine, did not start as an internal combustion engine. Some of the basic principles of it were discovered centuries ago before we had any of the modern hydrocarbon fuels such as gasoline or kerosene, so that those who expect the history of the gasoline engine to be a continuous chapter of development, with one kind of fuel, will be disappointed.

Hot-Air Engines First

The origin of the present-day gasoline engine started centuries ago in the form of hot-air engines. Here it might be added that an air engine is one in which the working medium is air, heated or compressed, as distinguished from steam in the steam engine, or a charge of explosive gas in an internal combustion engine, as we know it to-day. All three types, namely, air, steam and combustion engines, are heat engines. Heat is the great essential in all, and it is for this reason and because of this similarity existing among them that it is desirable to go back and carry the thread of development of air and explosive engines up through the centuries alongside of steam before entering into the history of the present-day automobile as dating from 1885 in Europe. All three forms of engines, air, steam and combustion, were developed very closely together under the same difficulties and for the same purpose. The inventors in one line have constantly made use of devices developed in another line, and in trying to give an accurate presentation of the facts as they occurred the difficulty is to show how closely they were related to each other in this early period rather than to attempt to separate them, as they have since in their respective growths separated themselves. It is particularly interesting to watch how the modern engine developed and how each step led to its successor.

Hero's Air Engine

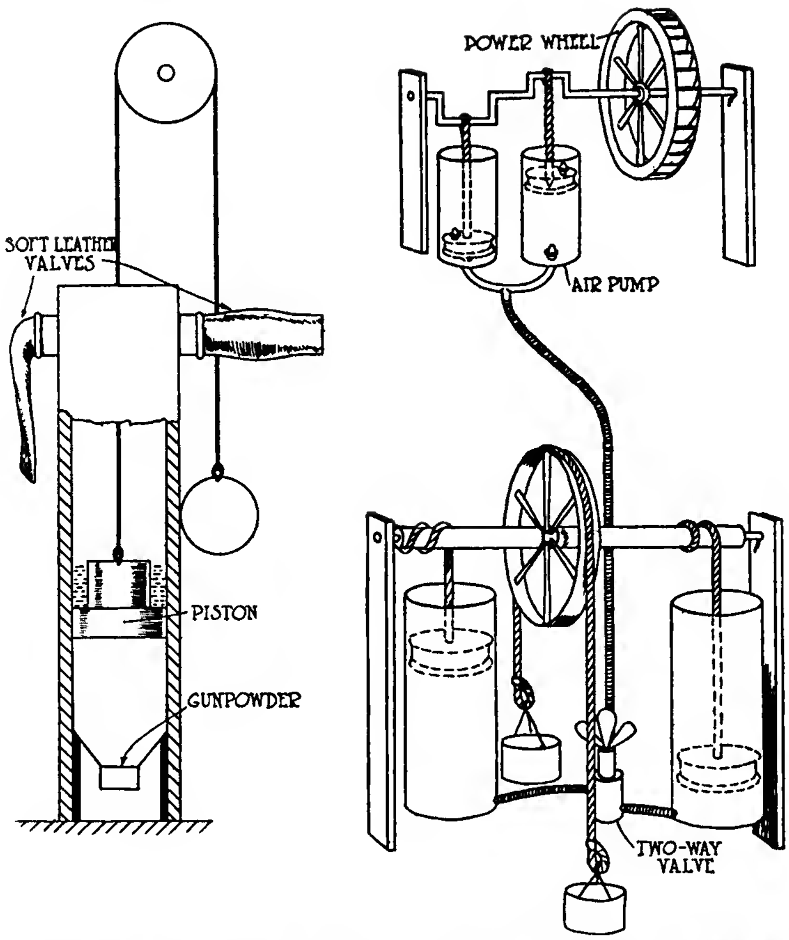
The first recorded use of expanded air to do mechanical work seems to be that of opening the doors of temples described by Hero, 130 B. C., in which a very simple contrivance accomplished the result. When a fire was built upon an altar the heat expanded the air contained in the hollow underneath the altar, which air forced water out of a bottle into an open pail through a curved pipe or syphon. The weight of the water in the pail opened the doors against counterweights. When the altar cooled the water syphoned back into the original bottle, lightening the pail and permitting the counterweights to close the doors.



Hero's device, the first known to do mechanical work with expanded air. It was used for closing the doors of temples. A fire on the altar heated the air in a hollow beneath it so that it forced water from a bottle into an open pail through a syphon, the weight of the water opening the doors against counterweights. When the altar cooled the water syphoned into the bottle and as its weight was removed from the pail. the counterweights closed the doors.

After the invention of gunpowder the Abbé Jean Hautefeuille of Orleans, France, in 1678, described a perpetual pendulum which was a sort of cannon in which gunpowder explosions were produced and which could be employed to raise water much as a modern pulsometer pistonless steam pump.

Two years later Huygens, Holland, described a gunpowder engine consisting of a cylinder open at the top and fitted with a screwed breech in which gunpowder could be placed and fired. The ignition of the powder filled the cylinder with flame and gases, driving the piston to the top and then escaping through exhaust valves formed of leather tubes. These tubes would flatten immediately and prevent air from entering until the piston had passed them on its downward movement, which movement was accelerated by atmospheric pressure, the gases inside cooling and condensing as the piston went downward. A rope over a pulley with a weight on the other end served to communicate power to the pulley shaft. This engine is, therefore, seen to be a complete device depending solely upon the means for introducing and firing the powder, and limited mostly by the cost of fuel. About the same time Papin, France, was working along much the same line, except that he gave preference to steam instead of powder.



Left—Huygens' gunpowder engine, in which the flame and gas of the explosion threw the piston upward, the leather exhaust tubes flattening as the piston dropped and preventing air from entering until the piston passed them. A rope, pulley and weight communicated power to the pulley shaft.

Right—Papin's engine, which was built along lines similar to the Huygens construction except that steam instead of powder was used. This engine was used or raising any sort of weight out of a deep mine.

John Barber's Patent

John Barber of England took out a patent in October, 1791, in which he shows two retorts to be used alternately, one being cooled and cleaned and refilled while the other is in service. These retorts, being heated gave off vapors that could be burned, and these vapors passed to a water-cooled holder. Air, water and gas from this holder were all pumped to an exploder chamber. When flame was applied to the outlet of this chamber a violent blast resulted, which, being directed against a multiplicity of vanes projecting from the rim of a wheel, caused the wheel to turn. His pumps seem to have been slow acting, and so this blast effect was most likely not continuous. His mechanism would undoubtedly have served much better if used with a piston and cylinder than with a turbine which could not have had much efficiency.

Another Englishman, Thomas Mead, in 1794, patented a very crude device for generating either vacuum or pressure by the use of heat. This was a large cylinder with cocks at top and bottom and a grate for carrying coals which could be introduced by removing the top head of the cylinder. When the top head was replaced the grate would be released and allowed to move downward as the air below passed through the grate, which passage heated and expanded it and created a pressure and volume that could be used to perform work. If not otherwise used this pressure would drive downward a piston fitted near the bottom of the cylinder. When the grate reached its limit of downward movement, opening and closing the top cock would reduce the pressure to zero, followed by cooling of the hot gases and a vacuum which would raise the piston. Then, opening both cocks, the grate would be raised, expelling the burned gas from above it and drawing fresh air in below. The operation would then be repeated until the coals were burned and the grate had to be taken out for recharging.

Robert Street's Heat Engine

In May, 1794, Robert Street, also an Englishman, patented an engine driven by the force of inflammable vapor produced from "liquid, air, fire and flame." It seems that he used the vertical cylinder with its bottom or head heated practically red hot. On this he dropped tar, turpentine, or some similar liquid easily and quickly vaporized, which vapors, mixing with air, drawn in by a short initial lift given the piston, drove the piston upward, possibly by a hand lever and ignited by a torch, escaping at the top of the stroke and followed by a return or downward movement of the piston, doubtless assisted by atmospheric pressure. That he understood and used the device is shown by his statement that ten or twelve drops of fuel should be used with each cubic foot of air drawn in.

Requirements of Tractor Design

Three Schools of Tractor Engineering Produce Different Machines—Tendency Towards Automobile Engineering Rather than Gas Engine Construction*

By C. M. Eason

Engineer Hyatt Roller Bearing Company

WHILE the detail of tractor construction is different from any other, yet it is possible to group tractors under three general classifications. First: the heavy type based on stationary engine practice; Second: the so-called automobile type, embodying a great many features found in present day automobile construction; and Third: a composite type, which, in a modified form, contains certain features common to either of the other two types. Back of every tractor design are certain specific reasons for the construction used. It will doubtless be of interest to present some of these reasons as advanced by the engineers responsible for the different designs.

The builders of the heavy type tractors declare that any machine to be a success at farm work must be made very heavy to stand the rough usage and continuous service. To this end they employ slow speed single or double cylindered motors having rather large cylinder dimensions. They make all of the bearing surfaces extremely large, using babbitt or bronze bushings practically throughout. The transmission systems of these tractors are usually rough cast gears of coarse pitch and large diameter. Owing to the difficulty of inclosing these large gears they are usually run in the open, and some mechanical means of lubrication for the gear faces is employed. Frames and wheels are also necessarily very heavy. The carburetion, ignition and cooling systems are usually reduced to the utmost simplicity, and, being designed for practically constant speed and load, there is very little necessity for fine adjustment or flexible control. They point to the fact that all other farm machinery is comparatively crude in design, cast and malleable iron, rough bar forgings and similar construction being used almost exclusively. They state that while this type of construction may be crude from a mechanical standpoint, that it is better understood and easier taken care of by the average farmer than a machine of higher mechanical refinement. They further state that a single-cylinder motor will give a farmer just half as much trouble as a two-cylinder, and one-fourth, as much trouble as a four, and being less sensitive to delicate adjustment will run for a greater length of time without proper attention than any other type.

The designers of tractors built along automobile lines claim that fundamentally the use of single or double cylinders or large diameters is incorrect for tractor duty, because it is necessary to make all of the design so extremely heavy to obtain proper wearing surface or bearing area. It is a well established principle of automobile motor design that the effective life is proportionate to the area of the uncooled parts (*i.e.* valves and piston heads), and to the weight of the reciprocating parts. Motors having small bores, small diameter valves, light pistons and light connecting-rods will show a greater effective life than motors of larger dimensions and heavier reciprocating parts. To substantiate this argument they point to the fact that automobile designers are working toward greater reliability with less attention and that this has led them to the development of six-, eight- and twelve-cylinder motors which have been proved to have a greater effective life than motors of equal horsepower by smaller number of cylinders. They further state that the life of a motor is dependent upon the ratio of bearing surface to piston area, and that it is possible to get a lower pressure per square inch on the crankshaft and connecting-rod bearings of a multiple-cylinder engine, than would be practical with single-cylinder motors of the same horsepower. It is also said that for a given power it is easier to build multiple cylinders than single cylinders due to the greater facility for handling small parts in duplicate. As to gears and shafts of the transmission system they point out that an alloy steel gear properly heat treated only weighs about 15 per cent as much as a cast iron gear for transmitting a given power, and that after taking into consideration the cutting, hardening and extra handling of the smaller piece they can actually be produced for the same or less money than the heavier gear of cheaper material. They also maintain that the only way to insure reliable operation in a transmission system is to absolutely protect same from dust and dirt and run it in a bath of oil. To accomplish this it is, of course, necessary to have dust proof and oil tight cases making self-contained units of the transmission system. This type of construction permits the use of some type of anti-friction bearing instead of plain babbitt or bronze and insures a high percentage of the motor power being delivered to the drive wheel.

Carrying out this type of construction to its logical conclusion will result in the production of a tractor weighing about one-third as much as a tractor built along the lines of the heavy single-cylinder, slow-speed motor. Whether this construction will be entirely too light for tractor service remains to be proved by actual experience in the field with tractors of each type working under similar conditions. So far there are, at least in fairly successful operation, tractors of both types. It would seem that an answer to the question as to which will predominate in the future must wait until more practical experience has been obtained.

Most of the experienced tractor designers of to-day have brought out during the past year, or are preparing to bring out next year, tractors which show plainly a combination of both the heavy type and the automobile type of construction. The arguments which they advance for this composite type are substantially the same as advanced by the advocates of the two extreme types. They qualify all of these arguments by saying that a tractor is neither a perambulating stationary power plant nor a pleasure car, and is unlike the motor truck, being a distinct and separate type of machine. Some of the tractors produced in this class have been developed from the stationary type as a basis and brought to their present form by cutting down sizes where permissible, using better materials where greater strength was required and applying anti-friction bearings at the points where the loads are heaviest. Others in this same class have been developed from the light weight construction, as a starting point, by building up and strengthening various parts as they have developed weaknesses in the field.

---

*Extracts from a paper read by Mr. Eason at an agricultural engineers' convention held recently in Chicago.

ACCESSORIES

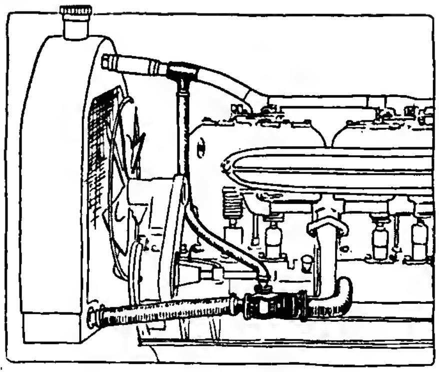
Sylphon Circulation Regulator

THIS regulator, which is already a standard feature of equipment with several car manufacturers, is designed to keep the temperature of the cooling water constant. When the engine is started the Sylphon device diverts the circulation until the temperature of the water in the cylinder jackets reaches a point at which the engine operates most efficiently, when it automatically starts a gradual circulation. The same temperature is maintained around the cylinders until circulation is complete. The device is a thermostatic arrangement using a metal coil which responds readily to changes in temperature.

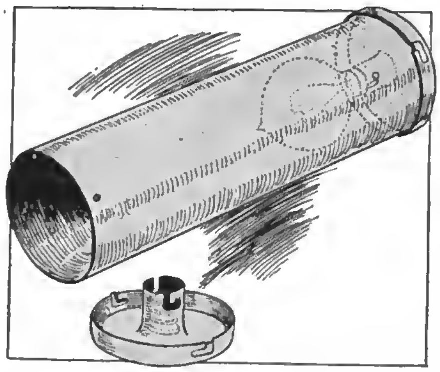
The regulator is claimed by the manufacturer to heat the engine to correct operating temperature 1 min. after starting, preventing backfiring due to cold cylinders; to render unnecessary carbureter adjustments due to weather changes; to promote lubrication; to reduce wear in cylinders and pistons by preventing inequalities of expansion and contraction; to prevent rapid cooling of the motor when not running, thus insuring quick getaway, and to reduce gasoline consumption and carbonization. The device is entirely automatic and is claimed to outlast the car on which it is mounted, no adjustments or repairs being necessary.—Fulton Co., Knoxville, Tenn.

Boyce Midget Model Motometer

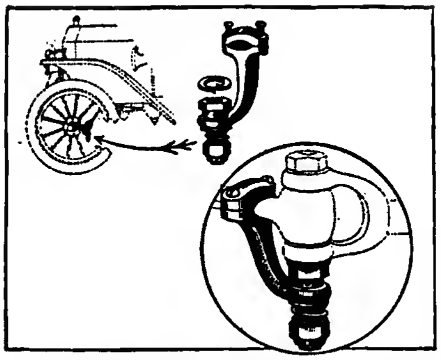
Similar in design and construction to the Standard and Junior models of the Boyce Motometer, the Midget is specially designed for use on small and light cars. It is accurate and well built, being 2¼ in. in diameter and finished in nickel with black dial. Like the Junior, it has no glass over the thermometer scale. A special center screw is required for mounting the device on Overland cars, this screw selling for 50 cents extra. The Midget model Motometer inserts through a ⅞ in. hole in the radiator cap and bolts in place. It sells for $2.50.—Motometer Co., Inc., New York City.



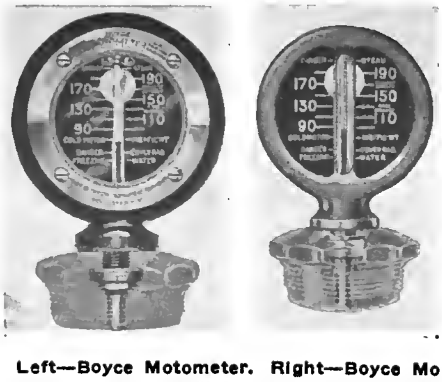
Sylphon circulation regulator



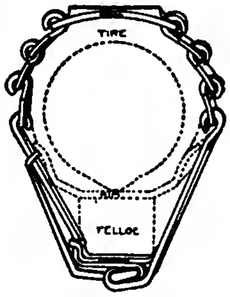
Dover electric bulb case



King anti-rattler for tie rods



Left—Boyce Motometer. Right—Boyce Motometer Junior



Kimball cam-locked non-skid chain

Kimball Skid Chain

Six clasps encircling the tire constitute the anti-skid provision for each wheel of the car. The clasps are locked by a cam device and when in place press into the rubber and stick to it. The clasp is flat steel ⅛-in. thick with a tread plate 3 in. wide and links 1¼ in. wide. A strip of leather prevents the marring of the varnish on the felloe. One or more of the clasps may also be used as a blowout patch.—Kimball Tire Case Co., Council Bluffs, Iowa.

Sapp's Accelerator for Fords

This foot accelerator is attachable to the Ford without machine work or fitting. The foot piece is attached to the top of the gearcase by two of the screws that hold the cover and connection with the throttle is made through a wire cable. A spring returns the throttle when the pressure of the foot is removed. The device does not interfere with the use of the hand throttle. The outfit weighs less than 1 lb. Price, $1.65.—Will A. Sapp, Elgin, Neb.

Dover Lamp Bulb Case

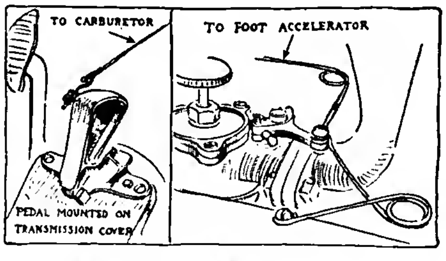
Two Ford headlight bulbs are contained in this 7½ by 2¼-in. cylindrical steel case, one bulb being held securely at each end of the case by spring-backed bayonet locks so that it can neither rattle nor work loose. The Ford bulb case, as illustrated, sells for 35 cents, without the bulbs. The company also manufactures cases for other assortments of lamps.—Dover Stamping & Mfg. Co., Cambridge, Mass.

King Anti-Rattler for Fords

These clamps are designed to prevent rattle due to a loose tie-rod on a Ford or Overland car. No machine work is required in installing a pair of the clamps and they may be attached in a few minutes. Price per pair, for Fords $1; for Overlands $1.50.—King Specialty Mfg. Co., Brookline, Mass.

Whitaker's Water Bags

Whitaker Egyptian water bags are woven of special flax and when filled allow a little moisture to exude, the evaporation of this keeping the water within cool despite hot weather. The tops are closed by a steel wire device which per-



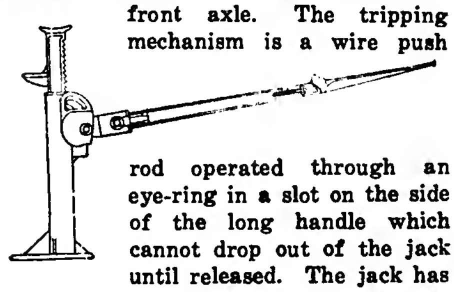
Sapp's accelerator for Fords

Whitaker's bag for cooling water

mits the bag to be turned inside out for cleaning and drying. The ½-gal. open top type bag sells for 95 cents, the 1-gal. for $1, 2½-gal. for $1.50, 3½-gal., $2, 5-gal., $2.50. Furnished with closed top, the ½-gal. size is listed at 85 cents, the 1-gal. at 90 cents, 2½-gal. at $1.35, 3½-gal., $1.85 and 5-gal., $2.25.—Whitaker Mfg. Co., Chicago, Ill.

Hartford Red Rack Jack

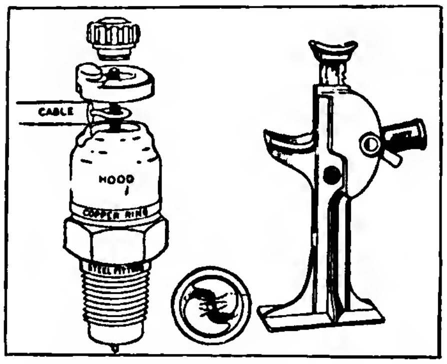
One of the main advantages of this jack is that it can be placed under the axle of the car and raised and lowered by the operator from a standing position, it being unnecessary to crouch under the rear of the car. This is accomplished by means of a 26-in. hinged extension lever handle which, when folded, is only 14½ in. long and which is easily detached by depressing a spring. The jack has heavy double ratchets and pawls and an extra step for use under a low front axle. The tripping mechanism is a wire push rod operated through an eye-ring in a slot on the side of the long handle which cannot drop out of the jack until released. The jack has a range of 11 to 18 in. on the head with a further minimum of 8⅝ in. for the front axle step. The jack weighs only 7 lb., although the ribbed base is very broad to give perfect stability. The name is derived from the red enamel finish of the toothed rack, the rest of the jack being finished in black. It sells for $2.50.



The company also manufactures the Hartford jack which operates by a ratchet, a pinion meshing with a large gear, the movement of the latter being directly communicated to a pinion engaging the rack on the moving upright. This jack is finished in black enamel and packed in a canvas bag. It lists at $6.50.—Hartford Suspension Co., Jersey City, N. J.

Hinckley Milling Attachment

A drill-press is converted into a milling machine by the use of this device and will cut straight, taper or Woodruff keyways, straight or curved grooves, finish semi-cylindrical bushings and the like, and so on. The attachment, which will go on any drill-press from 14 to 42 in., consists of a 12½-in. circular base with graduated circle carrying traverse slides moving 12 in. longitudinally and 7 in. across, and a vise opening 10 in. T-slots are also provided in the table for clamping work that the vise will not accommodate. The cutters used are regular stock sizes and do not have to be specially made. They fit in the taper drill sockets. Price, $48.—Hinckley Machine Works, Hinckley, Ill.



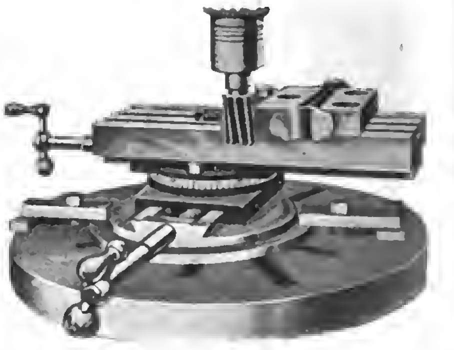
Left—Herz Pro-Mo-Tor spark plug for Fords. Right—Jiffy jack for garage use

Jiffy Jack for Garages

This new Jiffy jack is called the Indestructo and is intended especially for garage work. The short stroke permits the use of a long handle while the base is large. Its normal capacity is 2000 lb. though it will stand 100 per cent overload. The jack is 11½ in. high and the lift is 7 in., there being an auxiliary step 7 in. from the base. Price, $2.50.—Jiffy Jack Co., Cleveland, Ohio.

Herz Pro-Mo-Tor Spark Plug

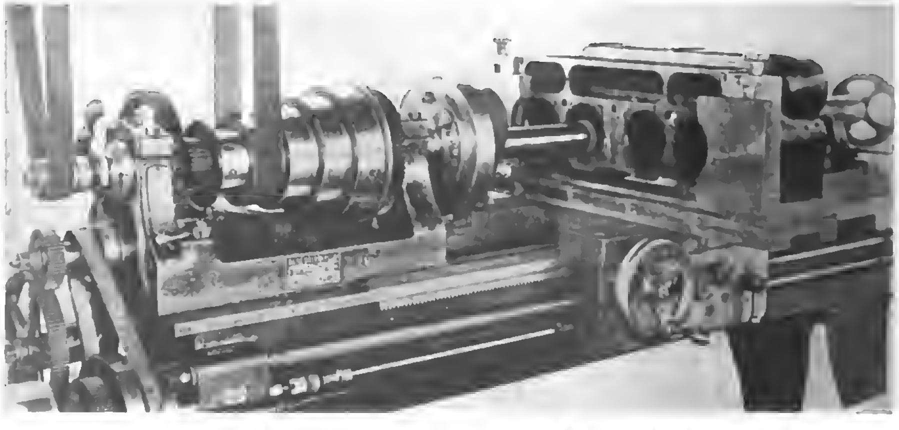
This plug, which is designed for Ford cars, is claimed to be self-cleaning, soot, water, dust and shock proof. A propeller-shaped disk forming the outside electrode is stated to prevent the settling of carbon and oil in the combustion chamber. This disk produces a whirling action which tends to keep the plug chamber clean. A rubber cap protects the high-tension cable terminal from water and dirt, fitting over the top of the plug as illustrated. The hood of the plug is stone with a copper ring fitted to its lower end. The plug sells for $1.—Herz & Co., New York City.



Hinckley miller attachable to any drill press

Woods Lathe Attachment

This boring and grinding attachment may be fitted to a 16-in. lathe and with regular equipment will bore and grind cylinders from 2⅛ to 5¼ in. in diameter and 11 in. deep. Both the grinder and the boring bar are attached to the lathe faceplate, the grinding arm outfit including the gearing for driving the two grinding wheels furnished, which are 2⅜ and 3½ in. in diameter, respectively. The spindle runs in S. K. F. double-row ball bearings and the drive shaft also runs on balls, all bearings being protected from dirt. An eccentric system is used for micrometer adjustments. The outfit includes the lathe attachment itself with grinding wheels and boring head, overhead countershaft, cross slide for the lathe carriage with two adjustable angle plates having vertical screw adjustment and T-slots for bolts, special faceplate, diamond grinding wheel, dressing tool and wrenches. The milling machine attachment is necessarily constructed to adapt the outfit to the miller.—Woods Engineering Co., Alliance, Ohio.



Woods boring attachment in place on 16-inch lathe arranged for grinding

Driver's Comfort

IF comfort is defined as the state of being at ease, there is no doubt but that there is room for improvement in a great many cars, particularly as regards the driving seat. No criticism can be made of the room in the tonneau of the 1916 car, but it is a question if some of this room is not being obtained at the expense of the driving compartment, thus providing a superabundance of space in the rear while the occupants of the front seats, especially the driver, suffer.

There are many important details about the design of the driver's seat, and not only do these details affect the sitting posture but also the convenience of control. The handling of the steering wheel, gearshifter lever, instruments on the control board, brake, clutch and accelerator pedals keep the hands and feet of the driver of such a variable-speed vehicle as the automobile constantly on the move. The movements of driving amount to a material total after the end of a day's run and careful motion study on the part of the designer would certainly be thankfully received by the occupant of the driver's seat.

Probably the driver himself would not be able to tell why he left the seat of one car feeling fresh and fit to continue the journey after a run of a whole day, while on another car he was weary before half the day was over. The position in the seat, reach for the pedals, position of the feet and arms, all have their influence. It is an important matter to have the driver's seat correct. The man who foots the bills of motoring should receive careful attention, and since 90 per cent of the owners of cars drive, it behooves the manufacturer and designer to realize what an important personage the driver is after all.

The Agricultural Tractor

THE revolutionizing influence of the internal combustion motor is once more demonstrated by the fact that separate tractor expositions are being held in the Mississippi Valley. Minneapolis is holding one this week, Kansas City will hold one next week. It is surprising that exhibitions have not been held before this date.

The expositions have a suggestion for the automobile dealer, who up to the present has not taken the agricultural tractor seriously, but who during the past year has realized that a large source of revenue is within his reach through the tractor field. Automobile dealers are the logical persons to handle the tractor business. They are familiar with the internal combustion motor, and because of this are in a much better position to give real service to tractor owners than many implement dealers to whom the internal combustion motor is not so well known.

After-War Exports

IN considering the position of the American automobile industry at the conclusion of the war, there is one point that is liable to be overlooked and this is that the ability of the European manufacturing industry to compete with imported American vehicles may be greatly different from what it was before the war. Practically every factory in Europe is now much better equipped than it used to be because every available plant is operating on munition work and great quantities of new machinery have been bought to facilitate the production of articles needed by the armies. As soon as the demand for munitions ceases the automobile plants of Europe will find themselves much better supplied with tools than ever before while they will also have workmen who have been trained to operate modern American machinery at a higher speed than has previously been the custom in Europe.

The opinion is now being expressed fairly freely in England and France that manufacturers will be able to make automobiles for considerably less money and that therefore it will be easier to fight American competition. The moral is that American manufacturers must be ready to meet severe competition and prepare for a drop in the average selling price of European cars. At present, in regard to the abnormal cost of Atlantic freight there is ample margin between the factory cost here and the selling price in Europe. Economies can undoubtedly be effected between the American factory and the ultimate European owner. The object is one that should be given close attention so that plans may be laid beforehand.

260,000 See Chicago Exhibition

30,000 Were from Out of Town—Ticket Rebates to Pay for Dealers' Space

CHICAGO, ILL., Jan. 29—As near as could be estimated by Manager Samuel A. Miles, 260,000 persons entered the Coliseum during the week of the Chicago show. This is about 8000 greater than the New York attendance. Of these, 30,000 were visitors from out of town and included dealers, salesmen, owners and prospective owners. There were 3500 exhibitors and salesmen; there were 3000 dealers from all parts of the United States and Canada; even one from South Africa.

Based on the attendance figures it is estimated that the exhibitors will receive on rebate from the ticket sales enough to pay for the rental of their space. The increase in attendance is about 22 per cent over last year's figure, according to Miles. Last year the show paid back to exhibitors who are members of the National Automobile Chamber of Commerce and of the Motor and Accessory Manufacturers over 80 per cent of the amount paid for space rental. The indications are this year that they will receive nearly 100 per cent.

From a business standpoint, the exhibitors are almost a unit in agreeing that the show surpassed any previous records set up by earlier events at Chicago. Most of them have found also, that it was a better business show than the recent New York exhibition. This is the opinion of accessory exhibitors as well as car exhibitors.

In accounting for the statements that when the sales results are checked up, the Windy City show will outshine that of Gotham, a number of theories are given. It is the belief of most that the territory from which Chicago draws its dealer attendance is less restricted than that of New York, and consequently the dealers at the Chicago show represent a greater buying territory. Add to this the fact that many dealers visit the New York show for a general view of the offerings and have come to a decision and are ready to close at Chicago. A rather interesting explanation is that given by some of the accessory men that dealers and jobbers go to New York for a good time and come to Chicago for business.

Lee and Michelin Tire Prices Raised

NEW YORK CITY, Feb. 1—General advances in prices for tires were announced yesterday afternoon by the Lee Tire Co. The puncture-proof tires have been advanced 15 per cent, while all other grades are 10 per cent higher.

The Michelin company this morning raised its prices 10 to 15 per cent. Though the Nassau prices are as yet unchanged, it is expected that before the week is over this company will announce a new schedule.

On its plain tread types, the Lee company has advanced its prices in some cases over $2 a tire, for instance on the 28 by 3 the new price is $19.75 as compared with $17.15; the new price on the 34 by 3 is $23.65 as compared with $20.45; and on the 36 by 4, the new price is $42.75 against $37.15. On its puncture-proof non-skid type, some of the advances range from $3 to approximately $7, as on the 36 by 4, which has gone up to $47.15 from $40.95.

Michelin plain tread prices on a few of its popular-sized tires are as follows: 32 by 4, new price $23.40, old price $20.95; 33 by 4, new price $23.90, old price $21.50, and 36 by 4, new price $26.30, old price $23.75. On its non-skid or Universal type, the prices are as follows: 32 by 4, new price $24.90, old price $22; 33 by 4, new price $25.65, old price $22.50, and 36 by 4, new price $27.95, old price $24.75.

Within the past week Firestone has increased its truck tire prices another 10 per cent. This is in addition to the 10 per cent increase announced earlier.

Chalmers Plans Canadian Plant

DETROIT, MICH., Jan. 31—Another local automobile company has decided to start manufacturing in Canada. It is the Chalmers Motor Co., and a Canadian Chalmers company has been incorporated under the laws of Ontario with a capital stock of $1,000,000.

A plant will be erected either in Windsor or Walkerville. The reason for this action, according to Vice-President Clarence A. Pfeffer, is that the tariffs or customs duty on automobiles and parts are becoming prohibitive to American manufacturers, and that the only way to do business profitably in the Dominion is to establish a manufacturing plant there.

Willis Is Chalmers Sales Manager

DETROIT, MICH., Feb. 1—Frank B. Willis, who was assistant sales manager of the Chalmers Motor Co., has been promoted to sales manager by vice-president of the selling division Paul Smith. Mr. Willis has been with the Chalmers company for one and a half years, being district manager for the company for the Eastern district at the time he was called here to the factory.

Two other promotions in the Chalmers sales division are those of T. H. Smith and W. J. Drumpelman, special representatives who become assistant sales managers.

12,000 Carloads Shipped in Jan.

N.A.C.C. Traffic Dept. Reports—Expects 16,000 Carload Shipments in February

NEW YORK CITY, Feb. 1—Reports from the N. A. C. C. traffic department give some idea of the increased production of motor cars during the month of January. During the first three weeks of the month members of the Chamber shipped 12,000 carloads of motor cars, and it is expected 16,000 will be shipped during the month. Last year only 8300 cars were shipped during the entire month. In other words, shipments have practically doubled. This greatly increased production is naturally handicapping railroads which have not enough freight cars to take care of the requirements. The work the Chamber is accomplishing is demonstrated by the fact that such railroads as the Santa Fé are hauling complete trainloads of empty automobile cars from California and Texas in order to get them back to the factories as soon as possible. Ordinarily these freight cars would be held and brought back loaded. Many of the factories are being regularly held up on shipments, several not having available railroad cars to take care of more than 75 per cent of their daily production.

75,000 Maxwells for 1916

DETROIT, MICH., Jan. 31—Production facilities of the Maxwell Motor Co. have now reached a stage where considerably more than the output of 60,000 cars planned for the fiscal year 1916 will be made. Officials say that they expect 75,000 cars to be made by the end of July, 1916, and that in the enlarged plant an annual output of over 100,000 is possible.

Maxwell to Have Canadian Plant

DETROIT, MICH., Jan. 31—Maxwell cars are to be made in Canada within the next few months, according to Walter E. Flanders, president of the Maxwell Motor Co. They will be made in a large plant to be erected in Windsor, Ont.

Chicago May Have Truck Show

CHICAGO, ILL., Feb. 1—During the Chicago Coliseum Motor Show last week a movement started looking toward the possibility of a motor truck show to be held in Chicago next year during the week of the passenger car show. Six or seven different representative manufacturers met and formally discussed the question, and a committee of one was appointed to take up with the truck manufacturers their attitude on such an exposition.

94,437 Overlands Built in 1915

Increase of 45,969 Over Output During 1914—722 in Day is Record

TOLEDO, OHIO, Feb. 2—The Willys-Overland Co. made and sold 94,437 Overland cars in 1915. This is at the rate of 315 per day on the basis of 300 working days.

In 1914 the number of cars made was 48,468, or at the rate of 161 per day during 300 working days.

The increase during the past year was 45,969, or nearly double the 1914 output.

The way production is now going on even the great record of 1915 will be far outdistanced, as production is now already at the rate of more than 700 cars a day, the record to date being 722 in twenty-four hours.

Congressman Calls for Investigation of S. O. Companies' Methods

WASHINGTON, D. C., Feb. 1—*Special Telegram*—A board investigation to determine primarily whether or not the segregated Standard Oil companies are boosting the price of gasoline was proposed to the House in a resolution introduced by Representative Dowell of Iowa.

The resolution proposed a general inquiry into the production, transportation, refining and marketing of gasoline and other petroleum products to lay bare the causes for the recent advances in the prices of these commodities.

Dowell's resolution calls for the appointment of a select committee to be appointed by the Speaker of the House and to consist of nine members.

Permanent Automobile and Accessory Showroom for Wall Street

NEW YORK CITY, Jan. 29—Taking advantage of the recent boom in war stocks during which many fortunes were made by curb brokers and others connected with the Wall Street section, R. J. Adams, Edwin Robins, and W. T. Savage have leased 15,000 sq. ft. at 50 Broad Street, on the ground floor, where they will establish a permanent showroom for automobiles and accessories.

It is stated that this section of the city at the present time abounds in many opportunities for sales in automobiles and accessories. It is expected that about twenty-five automobile manufacturers will be represented at the showroom and an equal number of accessory makers will show their wares. Up to the present time the following automobile makers have inquired for space: White, Apperson, Stutz, Packard, Overland, Pierce-Arrow, Mitchell, Mercer, Studebaker and Cole.

The delay in shipping conditions has held up the opening of the exhibition, but it is expected that by Feb. 15 enough of the new cars will be on hand to warrant a general opening on that date.

Messrs. Johnson and Dimond of the White and Apperson companies have been largely instrumental in the planning of this new venture. Though no company has as yet been formed, it is stated that a holding concern will be organized in the near future under the name of the 50 Broad Street Exhibition and Salesroom Co., with Edwin Robins, president and W. T. Savage, secretary and general manager. Each automobile maker will have his own salesman on the floor of the showroom.

Studebaker Declares Extra Dividend

SOUTH BEND, IND., Feb. 1—The directors of the Studebaker Corp. to-day declared a quarterly dividend of 1½ per cent, and an extra dividend of 1 per cent on the common stock; also the regular quarterly dividend of 1¾ per cent on the preferred stock. The dividends are payable March 1 to holders of record Feb. 19. The previous distribution on the common issue was 1½ per cent quarterly and 1 per cent extra.

Knowles Is Saxon Chief Engineer

DETROIT, MICH., Jan. 29—W. K. Knowles has been appointed chief engineer of the Saxon Motor Car Co., to succeed R. E. Coles, resigned. A. H. DeWees, formerly in charge of the chassis purchasing department of the Packard Motor Car Co., has succeeded R. M. Wirth, resigned, as purchasing agent.

Gifford with Paige-Detroit

DETROIT, MICH., Jan. 31—R. F. Gifford, who during the past six months was secretary of the Foreign Trade Bureau of the Detroit Board of Commerce, has become connected with the Paige-Detroit Motor Car Co. and will devote his time to building up the foreign business of that company.

McCrickett, Russel Engineer, Dies

DETROIT, MICH., Jan. 27—Thomas F. McCrickett, who was chief engineer of the Russel Wheel & Foundry Co.; former president of the Detroit Engineering Society and a member of the American Society of Civil Engineers, died Jan. 26.

Malcolm Co. Has $1,000,000 Capital

DOVER, DEL., Feb. 1—The Malcolm Motor Car Co. has been formed to make and sell automobiles and trucks. Its capital is $1,000,000. The incorporators are F. D. Buck, G. H. Dillman and M. L. Horty of Wilmington, Del.

S. A. E. Council in Session

Committee Chairmen Appointed—Members To Be Approved Feb. 16

CHICAGO, ILL., Jan. 28—One of the most successful meetings of the council of the Society of Automobile Engineers was held in this city to-day, at which practically all of the members attended, including President Huff and Messrs. Van Dervoort, Dunham, Utz, Coombs, Rose, Beecroft, Chase, Foljambe, Hall and General Manager Clarkson.

The meeting was called to complete the general organization of the season, as well as the announcement of the committees appointed by the president. The most important change in the committees was the resignation of K. W. Zimmerschied, chairman of the standards committee, and the appointment of A. Ludlow Clayden, engineering editor of THE AUTOMOBILE, to this position.

President Huff announced the chairmen of various other committees, but the personnel of the different committees was not decided upon. Among the chairmen nominated are the following: Finance, H. M. Swetland, Class Journal Co.; Meetings, George Dunham, consulting engineer, Detroit; Members, R. H. Coombs, Prest-O-Lite Co., Indianapolis; Publications, Herbert Chase, laboratory engineer Automobile Club of America, New York. It is expected that the various members of the different committees will be approved at the next meeting of the council to be held in Detroit, Wednesday, Feb. 16.

Several applicants were approved for membership in the society, these including S. H. Page, assistant engineer, the Union Gas Engine Co., San Francisco, Cal.; Wallace W. Tuttle, factory engineer, Van Blerck Motor Co., Monroe, Mich.; Burns Dick, engineer, Wagner Electric Co., St. Louis; Benjamin F. Schooler, Briscoe Motor Car Co., Jackson; and Watson R. Smith, Jackson Cushion Spring Co., Jackson, Mich.

Brosseau Federal Truck Vice-President

DETROIT, MICH., Jan. 25—Beginning Feb. 1, A. J. Brosseau becomes vice-president of the Federal Motor Truck Co., of which he has been a director and stockholder. Mr. Brosseau has been general manager of the Gale Mfg. Co., Albion, Mich., for the past twelve years.

J. C. Wilson Raises Capital

DETROIT, MICH., Jan. 27—The J. C. Wilson Co., which makes the Wilson truck and is also manufacturing tops, has increased its capital stock from $20,000 to $225,000.

Foreign Trade Import and Export Is Serious After-War Problem

Many Interesting Opinions Given at Convention of National Foreign Trade Council—Expedients to Prevent Dumping Discussed from Many Angles

New Orleans, La., Jan. 29—The three-day convention of the National Foreign Trade Council, held in this city Thursday, Friday and Saturday of this week, has been one of the most valuable meetings for the consideration of sane problems in connection with foreign trade. Automobile interests have been directly and indirectly represented and all automobile concerns, hoping to develop their export trade, have lost a favorable opportunity of getting closer in touch with foreign business than they have had during the past year. While the convention did not discuss the automobile industry in general, there were many papers presented and discussions carried out that had a direct bearing on the subject.

Team Work Required

The problems of what conditions American manufacturers will face at the conclusion of the war were discussed from many angles. Alba B. Johnson, president of the Baldwin Locomotive Works, declared that a truly foreign trade policy on the part of the United States is necessary to meet conditions after the war. In the words of President Johnson, "It will be necessary for us to learn team work, by which is meant corelation of the efforts of the manufacturer merchant, banker and investor. Hitherto our bankers have been reluctant to enter the field of foreign finance; commission houses have too frequently been free lancers, pushing trade along the lines of least resistance or not in such a way as to create permanent and reliable trade. Our manufacturers have to fight single handed for their foreign trade and it is wonderful how well they have succeeded in view of the conditions of competition which they had to meet."

In referring to the possible trade conditions when the present war is ended, President Johnson said, "When the first peace negotiations begin, the uncompleted portions of all the vast volume of foreign war contracts, which are being executed in this country, will be suspended. Thousands of men will be deprived of employment, numberless inflowing streams of gold and profit will be stopped, and business of every kind will suffer a dislocation. In Europe the return of men now under arms, together with cessation of work on arms and munitions will alike affect the belligerent countries as well as ourselves, and great numbers of men will be forced to seek employment.

"Except in war stocks and automobile finance, there has been no undue financial expansion in this country. A guarantee of safety is to be found in continuing this conservative course. There can be little danger of a shortage of money after the war, because the money now employed as working capital in filling war orders will be released, and because the demands from Europe for war loans will cease. The amount of idle money will be large, until reabsorbed in legitimate enterprises at home and abroad."

The policy of selling merchandise in foreign countries at a lower figure than sold in the home market, a situation which the automobile industry has had to face for several years, was defended by Henry C. Emery, former chairman of the United States tariff board. Mr. Emery declared that selling goods in one market, such as South America, cheaper than in the home market was economically sound and that the United States Government should not hastily adopt any anti-dumping policy which might lead other nations to retaliate against the American foreign trade in manufactures, many of which are sold cheaper abroad than at home.

Dumping Not Sporadic

In his defense Mr. Emery referred to common misconceptions regarding the general policy of manufacturers in selling products lower on the foreign market than on the home market. The practice of dumping, he said, is as old as the world market, and is continuous rather than sporadic. The real danger which threatens us after the European war is not that European manufacturers will sell goods in our market below their own cost production, but that they will sell goods below our cost at home.

After pointing out several common fallacies regarding dumping, and showing that it was a natural and unpreventable form of trading as long as the world markets remained much as at present, Mr. Emery expressed disbelief in the effectiveness of most of the schemes suggested for the prevention of dumping in America after the war. He said that in his opinion the only plan was to institute a "bargaining tariff" scheme adaptable to meet constantly changing conditions. He stated that the foreign manufacturer could often get around an anti-dumping clause of the sort that have met with a good deal of favor, and that the foreign manufacturer would generally prefer a 25 per cent tariff plus an anti-dumping clause to a straight tariff of 35 per cent.

Prices in foreign markets are so low that the American exporter is largely driven by the sheer force of international competition to sell his surplus at some reduction. For this reason, the movement for an anti-dumping law will prove dangerous.

In speaking on this same subject of foreign countries selling abroad at lower prices then at home, M. A. Oudin, manager of the foreign department of the General Electric Co., said that this policy is generally followed out by foreign concerns. Export co-operation on the part of American manufacturers will lower the cost of distribution. The actual situation confronting American exporters is that there exists on our statute books federal laws which prohibit co-operation, although intended solely for the prosecution of the export trade of this country. In other words, the existing anti-trust laws enacted primarily for the benefit of the domestic consumer, by prohibiting monopoly and restraint of trade, and by increasing competition between manufacturers and producers at home, are equally applied to the regulation of our foreign commerce.

The net results are an impaired efficiency of our exporting methods and the creation of destructive competition among American manufacturers in their foreign trade. The foreign buyer is favored by frequently obtaining unnecessarily low prices; the American exporter is often injured by losses in his business, and finally our competitors have a freer field in which to operate.

Co-operation Helpful

Co-operation among manufacturers selling small articles such as automobile accessories in foreign fields was advocated by H. C. Lewis, general manager, National Paper and Type Co., New York. He referred to small accessories manufactured by a number of different manufacturers, none of which may be in sufficient demand to warrant the establishment of individual selling agencies, and all of which must meet with keen foreign competition. Such articles of constant consumption, sold at low prices, and at small profit, with prompt and regular deliveries must be the ultimate basis of the great and permanent foreign business which is desired.

Speaking on this Mr. Lewis said: "To sell our staple articles abroad and with profit requires the greatest possible efficiency and economy of operation. Competition among ourselves will necessarily increase expense and reduce profits, while co-operation in the proper spirit will give us larger business and increased profits. It must be recognized that an efficient selling organization can only be maintained at great expense, and that it must have the benefit of substantial capital to perform its functions. A small organization is not only less efficient but it necessarily has greater difficulty in raising capital needed. We are a big country and we need big business organizations to represent us abroad."

Speaking on this same subject of co-operation of smaller manufacturers in pursuing their export trade, L. S. Smith of the American Laundry Machine Co., Cincinnati, was convinced that the smaller American manufacturers should be allowed to combine to create a demand for their products in the foreign market. The smaller manufacturer will be at a decided disadvantage so long as we have to depend on the carrying of our cargoes by steamship companies owned in countries which are our most active rivals.

Gilbert H. Montague, counsellor at law, New York City, drew a vivid picture of the handicap which American manufacturers are working under because the present laws do not afford co-operation among manufacturers, with the result that American exporters are competing among themselves in foreign markets, whereas the great object should be co-operation among themselves and competition against other countries.

Here is Mr. Montague's picture: "Imagine a squad of recruits responding patriotically to the country's call for the foreign service, paying out of their own pockets for their equipment and training, studying in solitude the use of their equipment, with no assistance from the government except a correspondence course of instruction, being sent to the front with the plaudits and best wishes of their grateful country, and with a warning that if they ever fight or even drill as a co-ordinated army, or in any way accept as unrelated individuals, they will be liable when they return home to court martial and public disgrace. That is the position of our exporter to-day."

Purchasing Agents Assn. Formed

DETROIT, MICH., Jan. 26—The Purchasing Agents Assn. has been formed here, the members being purchasing agents in local manufacturing concerns. its object is both business and social. Dinners and meetings are to be arranged at which matters concerning the agents' duties and business will be discussed, such as good management of purchasing departments, scientific buying and co-operation with salesmen.

The officers elected are: P. E. Stroup, Dodge Bros., chairman; T. W. Tracy, Paige-Detroit Motor Car Co., vice-chairman; T. F. Thornton, Detroit Steel Products Co., secretary; F. W. Boynton, Packard Motor Car Co., treasurer.

Ford Detroit Plant to Be Doubled Within the Next Two Years

$10,000,000 to Be Spent on Buildings and Equipment in That Time—Output of 1,000,000 to 1,500,000 Cars a Year Is Plan—Payroll Will Approximate 100,000

DETROIT, MICH., Jan. 27—Ten million dollars, possibly a little less, probably a little more, will be expended by the Ford Motor Co., in doubling its plant here. The erection of duplicates of most of the present buildings is part of the plan, while many of the structures of the present factory will be considerably extended. New buildings and additions will cost probably more than $2,000,000, and for new machinery, tools and equipment in general, an expenditure of from $6,000,000 to $8,000,00 is expected.

If the water problem, about which the village of Highland Park must first be consulted, is solved satisfactorily, and a duplicate of the present, as yet unfinished power plant is put up, it will mean an additional expense of at least $1,800,000 which is not considered in the above figures. A working force of at least 60,000 men, and very likely 75,000 will be on the company's payroll when the revised and modernized Ford plant is in full operation. An output of not less than 1,000,000 Ford cars annually and more likely 1,500,000 will, according to officials, be a fact within a few years.

This factory extension program is entirely independent from the big Ford plants to be put up in the River Rouge and Dearborn districts where the Ford tractor plant, the steel mills and possibly the tire plant are to be located, which will require another army of at least 25,000.

Plan Well Matured

As was reported in THE AUTOMOBILE during the past year whenever purchases of land or property had been announced by the Ford company, they were the beginning of this contemplated enlargement plan. These plans might have been announced several months ago had it not been for several acres of land adjacent to the present Ford plant, concerning which negotiations had been going on for a very long time, and which were absolutely necessary to make the Ford project a possibility. These few acres of land were finally bought last December and the documents were duly signed only recently so that no announcement was possible until this matter had been settled.

The most important feature in connection with the new buildings will be the erection of a foundry in which castings for an output of at least 5000 Ford cars per day will be made.

The architects and draftsmen are still working on the plans for the many new structures, and information is thus only of a general nature at present.

The first new building to be started will be a duplicate of a six-story structure, 245 by 945 ft. on Manchester Avenue, this addition being rather an extension to this structure, its total length will thus be 1890 ft. At the end of this avenue, right near the boundary line of the Ford plant's property, another six-story building, 245 by 945 ft. is to be erected. On the Woodward Avenue side of the Ford plant, the factory building right behind the general office building, is to be extended 800 ft. to the north, giving the plant a width of about 1650 ft. on the avenue. In front of this factory extension there will be a duplicate general office building, four stories high. All the present one-story shops which extend hundreds of feet into the yards are to be enlarged so that their total length will probably be about 1650 ft., and all will be made into four-story buildings.

Price to Be Cut

Although Henry Ford did not say that there will be a great reduction in the price of the Ford car when the new plant is in operation, he let it be known in a roundabout way that the new manufacturing system, the increased production, the purchase of larger quantities of materials and other necessities, will contribute in reducing manufacturing cost and that both the company and the Ford purchaser will benefit by it.

Just how much land Mr. Ford or the Ford Motor Co. purchased in recent years is not known to outsiders. It is estimated that land purchased within the vicinity of the present parent plant totals more than 200 acres, the last of the purchases being made in December, 1915, consisting of about twenty acres and costing, it is said, about $500,000. In March, 1915, the Ford company purchased 56.7 acres of land on Woodward Avenue, almost directly opposite its plant, from the Chevrolet Motor Co., the price paid being, it is said, $580,000. Other purchases were made, it is claimed, in the vicinity. In an entirely different section of the city, or rather far from the Highland Park plant, between 700 and 1000 acres of land were purchased last year for the new steel mills, tractor plant, tire plant and workmen's city.

November Exports Are $8,322,601

5243 Cars and Trucks Shipped Abroad—1553 Trucks and 3690 Passenger Cars

WASHINGTON, D. C., Feb. 1—The tremendous increase in the export trade in automobiles in November last as compared with the corresponding month of 1914 is vividly shown in the figures just released by the statistical bureau of the Department of Commerce. Looking over the figures one finds that in November last 1553 commercial cars, valued at $3,837,307, were shipped abroad, while in November, 1914, the number was 842, and the value $2,244,518.

The passenger cars exports in November last amounted to 3690 cars, valued at $2,791,507, while in November, 1914, the number was 776, and the value $634,659. The exports of parts, not including engines and tires, amounted to $352,567 in November, 1914, and to $1,693,787 in November last.

These are the figures for the eleven months' period of 1915: Commercial cars, 20,418, valued at $55,913,713; passenger cars, 38,205, valued at $32,334,734; parts, not including engines and tires, $14,508,596. For the corresponding period of 1914 the figures are: Commercial cars, 2151, valued at $5,598,027; passenger cars, 21,038, valued at $18,523,010; parts, not including engines and tires, $5,208,090. The exports by countries are shown in the accompanying tabulation.

McLean Tire Elects Officers

CLEVELAND, OHIO, Jan. 31—The organization of the McLean Tire & Rubber Co. was completed Saturday by the election of the following officers: President, J. C. McLean; vice-president, W. B. Davis; secretary, G. W. Stewart; treasurer and general manager, T. J. Holmden. Most of the men interested in the new company are connected with the M. & M. Co., wholesale and retail dealer in accessories.

The old Morgan & Marshall Tire & Rubber Co.'s plant at East Liverpool, Ohio, purchased some time ago by the new company, will be put into operation about Feb. 15, with G. W. Greene as factory manager. It is the intention of the management to turn out about 500 complete tires per day.

R. S. Drake, Formerly Editor of "Motor World," Dies

NEW YORK CITY, Jan. 29—Roy Stannard Drake, editor of *Automobile Topics*, died yesterday morning at his home in this city of pneumonia. He was born in Cleveland and was in his thirty-sixth year. His activities in automobile journalism followed some years of work for the Cleveland *Plain Dealer*, Cleveland *Press* and the Washington *Press*, where he reported Senate affairs.

Mr. Drake later joined the advertising department of the Winton Motor Car Co., Cleveland, and following this connection he became advertising manager for the Post & Lester Co., Hartford, Conn. His automobile journalistic career began when he joined the editorial department of the *Motor World*, this city. Afterward he became editor of the *Bicycling World*. When *Automobile Topics* was purchased by F. W. Roche, Mr. Drake became its editor. He is survived by his mother and an aunt.

Packard to Boost Citizens Only

DETROIT, MICH., Jan. 31—Beginning to-day the cosmopolitan population of workers within the plant of the Packard Motor Car Co. is being told through posters and hand bills that their future advancement or promotion to any position of responsibility or trust, in fact, practically any kind of better position than that of mere factory or shop worker, will depend first of all as to whether they are or have started to become American citizens.

83,128 Cars i
Canada

Chalmers 6-40 to Sell for $1,450 After March 1

DETROIT, MICH., Jan. 26—Because it now costs $118.22 more in raw material to build the Chalmers 6-40, the Chalmers Motor Co. decided to-day that the price of this model, which now is $1,350 f.o.b. Detroit, will be $1,450 beginning March 1. All orders received up to midnight, Feb. 29, will be filled at the old price, or $1,350.

To illustrate the increase in price of materials the Chalmers company says that high-speed steel which formerly cost $1.05 per pound is now quoted at $3.35 per pound. Vanadium steel which sold at $1.85 per pound a year ago now costs $8.50 per pound. Aluminum selling at 19 cents per pound three months ago is now quoted at 53 cents; copper has nearly doubled in price, selling at 24 cents or more now as against 14 cents per pound some time ago. Leather, which formerly cost 20 cents per foot, has been selling at 33 cents per foot, etc.

—

Harroun to Make Aero Motors

CHICAGO, Jan. 31—Ray Harroun, who has been identified with the motor car industry as a race driver, inventor of a kerosene carbureter and chief engineer of the Maxwell Motor Co., is about to put his versatility to a further test. During the week of the Chicago motor show, Harroun announced that he had severed his connections with the Maxwell company, with which he has been identified for the past two years, and that he would open a shop in Detroit where he will develop and ultimately manufacture on a commercial basis a popular-priced aviation motor. Richard Miles, who has been assistant to Harroun on the Maxwell staff, succeeds him in the position of chief engineer.

In addition to his aviation motor work, Harroun will construct a special racing car that he guarantees will cover a lap of a 2-mile speedway in less than 1 min. It will be a stunt car and not eligible for the regular speedway events, having a piston displacement of over 300 cu. in.

Liberty Motor Car Co. Incorporated

Secures Plant of R-C-H Co.—Percy Owen President and General Manager

DETROIT, MICH., Feb. 1—Several men of prominence in the motor car industry here have incorporated the Liberty Motor Car Co. with a capital stock of $400,000 to manufacture a low-priced car. Negotiations have progressed to the extent of securing the plant formerly occupied by the R-C-H Corp.

Percy Owen, who until recently was vice-president and sales manager of the Saxon company, and prior to that held the position of general sales manager with the Chalmers company, heads the new Liberty organization, and is also the general manager, and he has associated with him James F. Bourquin as vice-president. The latter was formerly general manager of the Paige-Detroit company and previously was superintendent of manufacturing of the Chalmers company. The Liberty engineer is R. E. Cole, who was the Saxon engineer, and H. M. Wirth, also a former Saxon man in the capacity of purchasing agent, will have similar duties with the Liberty. There are said to be several other men well known in the trade interested in the new concern.

Goodrich Statement Shows Good Profits—Officers Elected

AKRON, OHIO, Jan. 29—The directors of the B. F. Goodrich Co. at their annual meeting yesterday declared a quarterly dividend of 1 per cent on the common stock, payable Feb. 15 to stock of record Feb. 5 and a dividend of 3½ per cent on preferred, payable 1¾ per cent on April 1 to stock of record March 21, and 1¾ per cent on July 1 to stock of record June 20. No dividend has been paid on Goodrich common since the close of 1912.

B. G. Works was re-elected president of the corporation, W. O. Rutherford, formerly assistant sales manager, goes up a step higher, being made sales manager, succeeding H. E. Raymond, who becomes a vice-president. Mr. Raymond's position as second vice-president was abolished and he becomes a vice-president. He will continue in charge of sales, advertising and selling policy. The office of general manager, held by A. H. Marks, has also been abolished and he becomes a vice-president, but retains his duties as works manager. The duties of Mr. Marks are confined to general supervision of costing, compounding, development and construction. E. C. Shaw, formerly second vice-president, becomes another of the vice-presidents.

The net profits for 1915, after making proper provision for maintenance, charges, depreciation, bad debts and other items, amounted to approximately $12,200,000. This amount, added to the surplus carried over as of Dec. 31, 1914, of $3,100,000, shows undivided profits of approximately $10,500,000 after deducting the four quarterly dividends of 1¾ per cent on preferred stock outstanding, together with a provision of $1,100,000 for the redemption of preferred stock, and a further amount of $1,700,000 set aside for various reserves, which are shown in detail in the annual report.

In its statement the company claims an improvement during the past year in its financial position, as the amount of quick assets over current liabilities shows a gain of approximately $8,100,000. The current assets amount to approximately $31,250,000, and the current liabilities to $4,200,000.

The directors voted to retire 7000 shares of preferred stock prior to July 1, 1916. This makes a total retirement of 27,000 shares, covering the charter provision for retirement of preferred stock up to July 1, 1916. In regard to its sales in 1915 the company states: "While the directors are highly gratified over the results of 1915, they have taken into consideration that a part of the increased earnings for the year were due to causes which may not be permanent.

The preliminary statement appears herewith.

—

Knight Re-elected President

CANTON, OHIO—J. F. Knight was re-elected president of the Knight Tire & Rubber Co. at its annual meeting, held recently.

C. H. Knight was re-elected treasurer and C. T. Carlson was re-elected secretary. The balance of the board members remains the same as last year with the exception of Howard Fawcett, who was elected a director.

B. F. Goodrich Co.'s Preliminary Statement for 1914 and 1915

	1915	1914	Changes

F. W. D. Capital To Be $500,000

Increase from $250,000—100% Stock and 30% Cash Dividends

Clintonville, Wis., Jan. 31—Prosperous conditions were reflected in the annual report made to stockholders of the Four Wheel Drive Automobile Co., Clintonville, Wis. Although more than $100,000 was invested in buildings, additions and equipment during 1915, the company declared a stock dividend of 100 per cent and a cash dividend of 30 per cent. The capital stock is to be increased at once from $250,000 to $500,000, and the additional issue distributed among present stockholders. The 30 per cent cash dividend is based on a capitalization of $250,000. The Four Wheel Drive company now has an investment of approximately $200,000. A large amount has been set aside for further purchases of equipment and additions as necessary.

At the annual meeting, W. A. Holt, Oconto; A. W. Priest, Appleton, and J. Kalmes, Clintonville, were re-elected directors. Officers were re-elected as follows: President, W. A. Olen; vice-president, John Kalmes; treasurer, David Rohrer; secretary, Frank Gause. The directors presented a check for $1,000 to President Olen as an appreciation of his services during the past year.

Another Price Control Bill

Washington, D. C., Jan. 29—Accessory dealers will be interested in a bill introduced in Congress by Senator Ashurst of Arizona to protect the public against dishonest advertising and false pretenses in merchandising. One provision of the bill is that in any contract of sale by a producer of articles to any wholesale or retail dealer, where the contract constitutes interstate commerce, the producer shall have the right to prescribe the uniform prices and manner of settlement at which the different qualities and quantities of each article covered by the contract may be sold. Special provision is made, however, against monopoly or the control of the market for articles belonging to the same general class. The producer or vendor must file with the federal trade commission a statement regarding his contracts for sale and the scale of prices, and he must pay a fee of $10 for registration of such contracts with the commission. The bill was referred to the committee on interstate commerce.

Four Shares Chevrolet Equals One General Motors

New York City, Jan. 29—The Chevrolet-General Motors Syndicate announces that the offer of exchange on the basis of five shares of Chevrolet for one share of General Motors common was closed on Jan. 25. Offerings will be considered hereafter at not to exceed four shares of Chevrolet for one share of General Motors common. General Motors common is earning about $140 per share, and Chevrolet at the rate of $25. The additional Chevrolet shares which will be issued will pass into the strong interests which at present control General Motors, and little, it is stated, is likely to find its way to the market.

Republic Tire Prospers

Youngstown, Ohio, Jan. 28—Republic tire sales increased 69 per cent in 1915 over the previous year, according to a report from the Republic Rubber Co., this city, which held its fifteenth annual meeting last week. Taking all departments into consideration, the company had more business on its books Jan. 24 than on any date in its history and prospects are good. The usual cash dividends at regular rates were declared. The old officers were re-elected as follows:

President, T. L. Robinson; vice-presidents, L. T. Petersen and J. H. Kelly; secretary, C. F. Garrison; treasurer, M. I. Arms, 2nd.

There were two additions to the board of directors, as follows: H. M. Garlick, president of the Standard Oil Cloth Co., and R. E. Cornelius, president of the Mahoning National Bank.

David Tod, who has been on the board for some years was not re-elected, at his own request. The board of directors is as follows:

M. I. Arms, Robert Bentley, C. H. Booth, J. H. Kelly, L. T. Petersen, T. L. Robinson, John Tod, H. K. Wick, J. C. Wick, H. M. Garlick and R. E. Cornelius.

Rubber Prices Are Lower

New York City, Feb. 1—Tire prices are higher, while crude rubber quotations are lower. Yesterday fine up-river Para dropped 6 cents a pound to 73, as did Ceylon, first latex pale crepe, which closed at 75. The market as a whole is weak and quiet. Prices have fallen sharply from the recent high level, but manufacturers show no disposition to purchase any more than they are compelled to. A considerable increase in the arrivals of crude rubber was reported last week, and in the absence of any improvement in the demand the market weakened.

Notwithstanding the rise of 1 cent a pound in copper yesterday, the producers were not inclined to sell, as higher prices, it is stated, are in view. Lead has risen to $6.15 per 100 lb., and predictions are made that it will advance to $6.25 before the end of the week. Aluminum remained constant throughout the week at 53 cents a pound.

Steel prices remained unchanged. It is stated that automobile manufacturers are holding off orders under the present quotations. Bessemer is quoting at $32 a ton, while open-hearth is at $33. The makers are fighting for lower quotations. It is said that contracts placed last year by the automobile builders were exceptionally large, and some of this stock will tide them over.

A rise in petroleum again occurred last week. On Wednesday Kansas crude rose 5 cents a barrel to $1.30, and on Friday Pennsylvania crude rose 10 cents a barrel to $2.35. Gasoline prices are still quoting at 22 cents.

Sterling Motor Capital $705,000

Detroit, Mich., Jan. 29—The Sterling Motor Co., which makes the Sterling four and eight-cylinder motors, has increased its capital stock from $310,000 to $705,000.

Ford Opens Sales Convention

Detroit, Mich., Jan. 31—The most important convention of assembling, service and sales branch managers and assistant managers of the Ford Motor Co., began to-day at the parent plant. It is expected that about 100 or nearly

all of the higher officials having charge of sales and service of the Ford company throughout the country will take part in the week's proceedings.

There will be addresses, talks and discussions, on every subject which has some bearing on the Ford business. The men will be given particulars about the project of enlarging the plant, the question of increased output, the situation of the trade in general. The views of the branch mangers will have much to do with possible changes in selling policies, service matters, etc.

Maccar Directors Elected

SCRANTON, PA., Jan. 31—The annual meeting of the Maccar Auto Co., this city, was held yesterday, at which the following directors were elected: Worthington Scranton, C. H. Genter, Oscar Kleeman, A. B. Warman, W. E. Bittenbender, George Stevens, W. M. Gardner, W. A. Christ, E. S. Williams, P. L. Sylvester and L. M. Connell, who acted as secretary of the meeting.

New Starter Co. Formed

GRAND RAPIDS, MICH., Jan. 31—The Wolverine Starter Co. has been organized here with a capital stock of $10,000. A starting device attachable to any machine will be manufactured. J. Frank Carter, patentee, is president of the company.

Dividends Declared

Avery Co.; 7 per cent on preferred, payable Feb. 1 to stock of record Jan. 26. This cleans up four accumulated quarterly dividends of 1¾ per cent and leaves back dividends of 5¼ per cent.

Security Prices Drop

General Motors Goes Down 26 Points—Overland Drops 20 Points—Reo Higher

NEW YORK CITY, Feb. 1—A general decline in automobile and accessory issues occurred in the local Stock Exchange last week. Only a few of the issues showed substantial gains, these being Reo truck and car, with gains of 3¼ and 1½ points respectively, and Miller Rubber common, with 10 points. The rest of the gains were for the most part fractional.

General Motors Weak

The declines ranged from 1 to 26 points. General Motors, after showing a flash in the pan last week with a 21-point gain, dropped this week 26 points. Chevrolet sympathetically dropped with General Motors 7 points to 125. Maxwell was steady during the week. Studebaker common dropped 8¾ points. Willys-Overland common dropped 20 points. Incidentally this stock, after reaching a high mark of 268 in 1915, has shown no further tendencies to rise, but has gradually gone down, after the announcement of a new stock issue for the Studebaker company. Shortly afterward came the announcement of a new issue of Overland preferred stock. At the early part of this week the stock went below the 200 mark, or about 69 points below the high mark. Three-quarters of the $15,000,000 issue of convertible 7 per cent cumulative preferred stock has been subscribed for. The balance of the new issue is now being offered to the public at 106 and accrued dividend. These notes are preferred as to both assets and earnings and are redeemable as a whole or in part at the option of the company on 60 days' notice at 110 and accrued dividends on April 1, 1917, or any dividend date thereafter.

The Chalmers company has offered to shareholders the right to subscribe at par to $500,000 new 7 per cent cumulative preferred stock. The company had $2,000,000 preferred stock authorized and $1,500,000 was issued, of which somewhat more than $300,000 had been retired by sinking fund. The offering has been underwritten.

Detroit Exchange Makes Record

Quotations on the Detroit Exchange last week were higher. With the exception of a 22½-point drop in General Motors common and a 6¼-point drop in Studebaker common, the general tone of the market was better than in previous weeks. Continental Motors rose 25 points, as did Packard common.

On the Detroit Stock Exchange all previous sales records were broken Wednesday, when a total of 9850 regularly listed shares of stock, also $13,000 of listed bonds, were sold. Of the 9850 shares which changed hands, 4018 were Reo Motor Truck Co.'s shares, 2780 were Reo Motor Car Co.'s shares and 1585 were Maxwell Motor Co.'s common shares. The active transactions in the Maxwell shares was due to a rumor that a dividend would soon be announced for the Maxwell second preferred stock.

Buffalo Show Indicates Prosperity

Expanding Industries In and Near Buffalo Foster Strong Demand for Automobiles

BUFFALO, Jan. 28—The show which closed Saturday night was the fourteenth annual affair and was staged by the dealers' association which is composed of some twenty-eight members who represent the cream of the industry in the city. It was strictly a business show and was very largely attended by dealers from Western New York, many of whom brought their prospects with them and closed sales on the floor.

In general, business is in a flourishing condition throughout the Buffalo territory and this is particularly the case in Buffalo itself. As an example in point, industrial deals closed within the past thirty days indicate, on conservative estimates, on four projects alone a total expenditure of nearly $9,000,000 for building operations. During the past five years there have grown in Buffalo an average of ninety-five new industries per year, or 475 for the period. For comparison, the total increase in new industries in Albany, Syracuse and Rochester combined for the same five-year period is given as 128. All this industrial development in Buffalo has taken place since 1910, for, prior to that year, the city gained only twenty-seven new industries per year. Furthermore, this great growth has been solely within the city limits and does not take into account a number of large industrial interests which have located just without the city border.

As indicating the financial importance and buying power of the city, the latest United States census figures are illuminating. The capital invested in 1914 was $243,311,000, a gain of $50,270,000, or 26 per cent, over $193,041,000 in 1909. The value of products is given as $251,103,000 in 1914, as against $218,804,000 in 1909, the increase being $32,299,000 or 14.8 per cent. A comparative summary for the city for 1909 and 1914 is given in the accompanying table.

Bank Deposits High

The purchasing power of the city is well indicated by the bank clearings for the past five years when the total for all banks was $2,825,000,000, an average of $565,000,000 a year. In the preceding five years the average per year was only $411,000,000. The total deposits in Buffalo banks in the past five years has averaged $220,000,000 per year as against $154,000,000 per year for the preceding five years. In other words, the average annual increase in deposits during the past five years has been $66,000,000 as compared with the previous five years.

That portion of New York State which is controlled by Buffalo dealers is an important agricultural center, the principal products being fruit, mixed farming and dairy products. Grain also constitutes a fairly large portion of the State's agricultural productions, though the totals, of course, are not as impressive as those for some of the Western States. A comparison of the productions for the years 1913 and 1914 is given in the accompanying table.

Big Grain Receipts

The total amount of grain receipts coming into Buffalo in 1915 was 210,000,000 bushels. Of this amount 29,641,000 bushels is at present in storage in 100 ships in the harbor. The industrial importance of these grain shipments becomes apparent when it is stated that the item of labor alone for unloading these ships amounts to $1,795,500. Of this amount $745,500 goes directly to labor and the balance to the elevators. Another important feature is that in the spring there will be a total of from 150 to 160 ships in Buffalo harbor which will fit out there at an average outlay of $5,000 per boat, giving a total expenditure of $750,000. This is a conservative estimate in view of the fact that for the past three years ship owners have kept down outfitting expense to the minimum owing to lack of business, but 1915 having been a prosperous year more money will be spent this year.

A Navigation Center

How the importance of Buffalo, as a navigation center, has increased is shown by the fact that the number of ships arriving and departing from the port in 1905 was 8200 with a tonnage of 12,000,000. In 1910 the total number of ships dropped to 7400 but the tonnage went up to 14,000,000. In 1913 there were upwards of 10,000 ships with a tonnage of more than 19,000,000 and in 1915 the number of ships was 7255 and the tonnage had gone up well above 19,000,000.

The average Buffalo dealer covers eight counties in Western New York, including Genesee which, in the majority of cases, is the Eastern boundary. This territory has a total population of 1,008,572 and includes Niagara, 108,419; Erie, 567,347; Chautauqua, 116,575; Cattaraugus, 68,477; Alleghany, 40,216; Wyoming, 33,082, Genesee, 40,296; Orleans, 34,160. Some of the larger distributers have several other counties in addition and in some cases territory extends into Pennsylvania, including several counties across the border.

Buffalo, which is in Erie county, has a population of 454,630, according to the 1915 state census, and population figures have shown a consistent increase as follows:

1865	94,210
1875	134,557
1890	255,654
1892	278,727
1900	352,387
1905	376,587
1910	423,715
1915	454,630

According to the Secretary of State's office, there are at present about 13,250 cars in Buffalo. Registration figures for the 22 counties west of Onondaga show that for 1915 there were 72,874 cars in this territory. Up to Jan. 24, 1916, there had been registered 13,842 cars, and, as compared with the same period last year, this represents a gain of about 33 1/3 per cent.

According to some of the larger distributers, Buffalo dealers are taking cars freely at the present time, though there seems to be some hesitation in some quarters to stocking them during the winter months. This is being overcome, in some cases, by the distributer financing the dealer. One distributer, for example, agrees to carry his dealers for one car for every one they will buy, and this seems to be working out well.

It is stated that the rise in cost of gasoline—the present retail figure in Buffalo is 23 cents—has had a noticeable effect on the used car market, which is described as being very tight. It is hoped that there will be little, if any, effect on the new car market.

Electrics are selling more freely now than has been the case for several years, though the buying is confined almost entirely to pleasure cars. There are very few electric commercial vehicles in use in Buffalo, and there has been little, if any, attempt to push their sales.

One noticeable feature of Buffalo conditions is the marked tendency toward the use of trailers, particularly by the farming communities within a radius of 50 or 60 miles of the city.

Exact figures on the attendance at the show are not available, though it is estimated that the total probably will exceed 60,000 for the week.

Anderson Returns from Norway

CHICAGO, Jan. 31—Gil Anderson, winner of the Vincent Astor cup race, returned unexpectedly last week from Norway, where he has been for the last two months visiting relatives and touring his native land, and Sweden and Denmark as well. Anderson has made no racing plans for this season and if Harry Stutz sticks to his determination not to compete, the Norseman probably will be a spectator instead of a contender. He is now back at work in the Stutz factory.

To Build Premier Racers

Two Cars to Be Made for Hoosier Speedway Owners —Make Peugeot Parts

INDIANAPOLIS, IND., Feb. 2—The Premier Motor Corp. of this city will build this season two racing cars for the owners of the Indianapolis Speedway.

Although it was announced last week that the local speedway magnates would add two American-built mounts to their stable of four Maxwells and two Peugeots, the Hoosiers at that time refused to reveal the identity of the maker.

The arrangement with the Premier company was made possible by the fact that the concern has just been reorganized and is not ready as yet to start quantity production. Until plans for a manufacturing and merchandising campaign are completed, the company will have sufficient time to work on the special racing jobs.

In addition to building the two new cars, the Premier plant will turn out spare parts for the Peugeots, driven by Howdy Wilcox and Johnny Aitken in the Vincent Astor Cup event at New York in October. Several replacements are to be made in the French mounts before they can be campaigned, and it is impossible to obtain parts in war-ridden Europe.

Tractor Shows for Minneapolis and Kansas City

CHICAGO, ILL., Feb. 1—For the first time agricultural motor implement manufacturers are going to exhibit during the same week of the automobile show in Minneapolis and Kansas City. At Minneapolis a tractor exposition is being held this week across the street from Frederick Murphy's Mitchell agency. In Kansas City the exhibition next week is known as the first annual tractor show and will be staged under a huge tent placed in the Union Station Plaza. In this tent, 365 ft. long and 75 ft. wide, are twenty-six exhibition spaces, all of which have already been taken, and it is expected that thirty different makes of farm tractors will be on exhibition. In addition there will be a good exhibit of accessories for tractors.

The tractor show is being staged by the Tractor Club.

Indiana Service Managers Meet

INDIANAPOLIS, IND., Jan. 31—The midwinter meeting of the Indiana Automobile Service Managers' Association was held at the Severin Hotel Saturday, Jan. 15.

Papers were presented by F. E. Moskovics, commercial manager of the Nordyke & Marmon Co., on The Effect of the Service Department on Eventual Motor Car Design, and by Mr. Fox of the Cole Motor Co. entitled Automobile Electric Systems.

During the business portion of the meeting it was voted to amend the constitution so as to provide for a committee of standards, something along the line of the standards committee of the S. A. E. Three lines of work were recommended:

First, the adoption of a standard form for reporting complaints.

Second, the standardization of the size of information books and parts lists, both of automobile manufacturers and accessory manufacturers, so that the books which go out with the cars shall be of uniform size and shape.

Third, the recommendation to the N. A. C. C. with regard to a system whereby the N. A. C. C. shall make a list of accredited garages throughout the United States for the benefit of motor car manufacturers as well as owners.

The standards committee appointed is as follows: H. W. Cotton, McFarland Motor Co.; Mr. Blywise, Premier Motor Corp.; R. J. Elston, Wescott Motor Car Co.; J. D. Hopper, Remy Electric Co.; G. C. W. Breithwaite, Apperson Automobile Co.

San Francisco Has First Truck Show

SAN FRANCISCO, CAL., Jan. 25—San Francisco's first motor truck show opened to-day. The large Palace ballroom floor space was all taken by northern California truck dealers and factory representatives. Space has been taken by practically every truck now being sold on the Pacific Coast.

Among the power wagons on exhibit is the new Doane truck, a power vehicle of local manufacture which has but recently made its appearance. This truck is a low hung type which has attracted a great deal of attention locally already. The new Golden West Quad designed and built at Sacramento, Cal., is another feature card at the show. This four-wheel-drive and steer commercial car is expected to make great progress in California, where the excellent highways are proving daily the efficiency of the modern motor truck.

The Moreland Distillate truck of Los Angeles manufacture is well represented, a full line being on display. The Moore, built at Torrance, Cal., is also shown at the exhibit. Among the trucks of Eastern manufacture is the Denby, G. M. C., Reo, Dart, Metz, White, Hewitt-Ludlow and others. The railroad companies have granted excursion rates and the truck show is considered a real success. The truck dealers have agreed that if the show is a success, it will become an annual affair.

Shorter Races for Sioux City

300-Mile Contest Replaced by 50 and 100-Mile Events —Prizes $15,000

CHICAGO, ILL., Feb. 2—The 300-mile race, which the Sioux City Speedway Association has promoted for the past two years, will be abandoned this season and two events, one of 100 and the other of 50 miles, will be substituted. There will be no cut in the total prize money, however, as $15,000, the amount hung up last year, will be offered again in 1916.

The Sioux City promoters have come to this decision because they believe that the spectators demand more action than is provided by a 300-mile event.

Sioux City plans to stage two meets for non-professionals later in the season. One meet will be for small cars, such as Ford, Maxwell and others, while the other will be a free-for-all. The races will be run under rules similar to those drafted for the amateur drivers' event to be run on the Chicago speedway May 20.

Stutz in Corona Race

CHICAGO, ILL., Feb. 1—Earl Cooper will drive the fastest of the four Stutz cars, in the Corona grand prize that will be run on the circular asphalt course of the California city March 17.

Although Harry Stutz, the builder of the mounts, announced in the fall that he would not permit any of the cars to compete this season, it became known to-day that Cooper made a secret trip to Indianapolis three weeks ago to secure a Stutz for the Corona race and that he was successful. The car has been overhauled and tuned up and now is en route to the Pacific Coast.

Bob Burman will be another contender at Corona. He arrived from Los Angeles last week to attend the Chicago show. With the assistance of Harry Miller, he has overhauled his Peugeot on the pacific Coast and says that the French car is now in the pink of condition for a hard campaign.

Portland Concludes Successful Show

PORTLAND, ORE., Jan. 29—The seventh annual dealers' show closed here to-night, having been visited by about 20,000 persons during the week. Ninety-one passenger cars were exhibited in addition to a number of trucks and a good range of accessories. Simultaneously with the show, two dealers who had opposed the show idea at its commencement, staged a "salon" at the Multnomah Hotel, exhibiting fifteen passenger cars. As a special attraction they had the original Packard built sixteen years ago.

N. A. T. A. Formed By Dealers

New Body Succeeds Associated Garages of America—Has Strong Financial Plan

CHICAGO, Jan. 27—For the purpose of promoting better conditions in the automobile trade field, the National Automobile Trade Association was formed in this city to-day. Its membership is made up of automobile dealers and garagemen, and it also provides for the membership of those who operate repair shops, automobile machine shops, supply stores, tire stores, tire repair shops, and other similar businesses.

It is a successor to the Associated Garages of America, which was formed a year ago by leaders of the garage trade in Illinois. The latter organization did not move forward rapidly because of a lack of finances; the new organization, however, has a strong financing plan, and with a corps of about twenty organizers, will be able to establish a strong membership in a comparatively short time.

Robert A. Wilson of this city who has been engaged in insurance work has been made Secretary and takes full charge of reorganization. The president is Robert Bland of Evanston, who was elected one year ago to serve two years. The treasurer is F. A. Bean of Detroit.

The Associated Garages of America whose name has just been dropped had a membership of 1420, made up as follows: Iowa Retail Dealers' Association, 800; Garage Owners' Association of Illinois, 300; Garage Owners' Association of Michigan, 150; Garage Owners' Association of Ohio, 100; San Francisco Garage Owners' Protective Association, 70. Aside from these there are throughout the country scores of local and territorial associations which may later become interested in the new national body.

The new association proposes to extend its co-operation to the National Automobile Chamber of Commerce, the Motor and Accessory Manufacturers, the National Association of Automobile Accessory Jobbers, and the various car owner organizations throughout the country, in an effort to promote the best interest of the automobile industry from top to bottom. As a first step in its work the convention to-day was visited by a committee from the jobbers' association. The jobbers and the retail organization discussed one or two points of difference and it was discovered instead of being points of difference they were points of misunderstanding, and harmony prevailed at the close of the conference. Henceforward each organization will have a committee for co-operative work of this kind.

The retail association voted a protest to manufacturers against the practice of selling automobiles to consumers at the dealer's price in localities where the manufacturer has no dealer. This practice is said to be common with several manufacturers and the matter will be taken up with the National Automobile Chamber of Commerce.

Another practice condemned is the appointment of one-car dealers, men who are sold one car, given a dealer's contract, but who never buy any more cars. A vote of thanks was extended to those manufacturers who have announced that they will discontinue bringing out their new models in the middle of the summer. The next national convention will be held in Cincinnati in March, 1917, but in the meantime several State conventions will be held as the organization work progresses.

Newark Stamping Co. in Merger

NEWARK, OHIO, Jan. 29—The Newark Stamping Co., manufacturer of Thompson hose clamps, will merge into a new corporation to be known as the Newark Stamping & Foundry Co., taking over the Moser Pattern & Foundry Co. and the Huffman Plating Works, all of this city. The company will be capitalized at $50,000. It will manufacture accessories, pattern work, casting and plating and polishing and also metal stamping and spinning.

Officers of the company are: Chas. F. Sites, president; Fred W. Moser, vice-president; H. W. Alexander, secretary; E. F. Ball, treasurer and general manager. Mr. Ball has been actively connected with the automobile industry for fifteen years.

New York State Gets Automobile Fines

ALBANY, N. Y., Jan. 31—Fines collected by cities for violation of the motor vehicle act must be turned over to the State, according to a decision handed down Jan. 24 by the Supreme Court Justice, Chester. The cities, may, however, retain money collected in fines and penalties for violations of various city and park board ordinances, so far as they regulate the use of motor vehicles in the city.

The decision is the result of a test case brought by the State against the city of Buffalo.

Safety-First Show for Washington

WASHINGTON, D. C., Jan. 31—There will be a "safety-first" exhibit in which all of the government departments are taking an active part, from Feb. 21-26. Manufacturers and operators from all over the country are invited to be present, in order that they may see what the Government of the United States is doing in "safety-first" work.

Woods Co. Plans Gas-Electric

To Produce Coupe at $2,700—Deliveries by April—Four-Cylinder Engine Used

CHICAGO, ILL., Jan. 30—The Woods Motor Vehicle Co., Chicago, expects to announce next week a car of distinctly new type which combines all the ease of manipulation that has characterized the electrics it has been building for years with the speed and touring radius possibilities of the gasoline car. The combination also permits the dual power plants such that should either system get out of order the car may proceed on the other independently. The combination also is designed to give flexibility.

At the present moment it is expected to produce only the coupé as the first model this will sell at something under $2,700, and deliveries are expected on this by April. That the Woods company expect to produce a quantity of the new car may be taken from the fact that they are coming through the factory in lots of 250 as compared with the lots of 50 in which the present electrics have been produced. The car has been undergoing road tests for a year. The wheelbase is 105 in., which is 5 in. greater than that of the present electric model.

The design is based upon the provision of a gasoline motor and electric generator to provide current for the electric motor, either direct or through the intermediary of a storage battery. It includes a four-cylinder gasoline engine of Woods factory manufacture, an electric motor generator directly connected to the engine and a 20-cell storage battery of electric vehicle type.

At speeds below 10 to 15 m.p.h. the gasoline engine idles, being driven by the electric motor which drives the car and which receives its current from the storage battery. When it is desired to travel at higher speeds, the gasoline engine is brought into play and can be used either in conjunction with the storage battery or to supply current direct to the electric motor from the generator. The connections are such that when the engine is generating more than sufficient for running the car it automatically keeps the storage battery charged. The automatic cut-outs are arranged so that the battery charge is kept within the limits of dangerous undercharge, and sufficiently high charge to cause gassing.

Control of the whole car is by means of two small levers on the steering wheel which give all the forward and reverse speeds. the forward speeds being practically infinite in number. These controls also throw the gasoline engine into and out of play and also operates the electric brake. The 20-cell battery has sufficient capacity to run the car without the assistance of the gasoline motor for 35 miles, so that it is independent to a certain extent of the gasoline power unit. The battery is approximately one-half the size of the average electric vehicle battery which usually has approximately 40 cells.

The addition of the gasoline engine and its accessories is more than offset by the reduced size of the battery and other weight economies and the new car weighs considerably less than the present purely electric Woods of the same model.

St. Louis Plans Traction Show

ST. LOUIS, MO., Jan. 28—The National Tractor Manufacturing Association will give a demonstration with 100 tractors representing thirty-three factories in St. Louis July 31 to Aug. 5, 1916, it was announced here to-day by Frank E. Goodwin, chairman of the executive committee of the St. Louis Tractor Farming Association who was principally instrumental in bringing the demonstration to this city. Plans are being made for the accommodation of 50,000 persons.

Ford Interests in Highland Park Bank

DETROIT, MICH., Jan. 29—The Highland Park State Bank of Detroit has filed its incorporation papers. Its capital stock is $500,000, and among those interested as stockholders are some of the best known men in the local automobile industry. Among them are: Henry Ford and his son, Edsel B. Ford; James Couzens, Frank L. Klingensmith, Horace H. Rackham, Walter L. Dunham, Henry S. Morgan, Charles A. Dean, John W. McMeans, James T. Whitehead and George R. Andrews. Mr. Couzens owns 3909 of the 5000 shares of the bank. The latter is in reality a branch of the bank of the same name in Highland Park, just across from the Ford Motor Co.'s plant. Most of the stockholders are the same in both banks.

Detachable-Rim Inventor Dies

NEW YORK CITY, Jan. 31—Richard S. Bryant, factory manager of The Standard Welding Co., died recently, of cancer at the Post-Graduate Hospital.

He was one of the first to design a quick-detachable rim—a type still used to a large extent. He organized the Bryant Rim Company of Columbus, Ohio, which was later bought out by the Diamond Rubber Company of Akron.

National Completes New Offices

INDIANAPOLIS, IND., Jan. 31—One of the two new buildings recently erected by the National Motor Vehicle Co. of Indianapolis was their new office and engineering building. This has been completed.

Anti-Trust Law Involves Dealers

Attorney General Sues to Prevent Manufacturers from Limiting Territory

DALLAS, TEXAS, Jan. 30—Alleging violation of the Texas anti-trust laws, the Attorney General's department for the State of Texas Thursday afternoon filed suits in the Fifty-third Texas District Court at Austin against the Munger Automobile Co. of Dallas, the Olds Motor Works et al. of New Jersey, the Cadillac Motor Co. of Michigan and the Houston Motor Car Co. of Houston, Texas.

It is alleged by the State that the Olds Motor Works and Davis and Turney, its distributors in this State, violated the anti-trust statute by virtue of a sales contract made by them, which limited and restricted the right of Davis and Turney to sell the cars purchased from the Olds Motor Works to a certain fixed territory. Similar allegations formed the basis of the suit against the Cadillac Motor Car Co. and its distributors or dealers, the Houston Motor Car Co. and the Munger Automobile Co.

The relief sought by the State is an injunction permanently restraining defendants from further carrying out alleged illegal contracts and from hereafter making similar contracts. No moneys or penalties are prayed for, because, in the opinion of the Attorney General, the facts fail to show any intention on the part of the parties involved to violate the law. The contracts containing the alleged illegal provisions complained of were prepared by the general attorneys of the foreign companies and were believed by the parties operating under them to be in compliance with the law.

Similar suits, it is understood, are to be filed against a number of other concerns. If the district courts sustain the State's contention in these cases, it means that a dealer cannot be restricted to sell automobiles in any territory set out by contract, but that he has the right to sell and distribute cars to any point in Texas.

Page Buggy to Build Front-Drive Truck

MARSHALL, MICH., Jan. 30—The Page Bros. Buggy Co., of this city is said to be perfecting the organization of a new company which will make a front-drive truck designed by E. H. Oversmith. The truck is to be assembled at the Page plant and a selling organization will be formed in Detroit from where the product is to be disposed. It is also stated that the new concern will be capitalized at $100,000 all of which has been subscribed.

20,000 Chandlers for 1916

CLEVELAND, OHIO, Jan. 30—The Chandler Motor Car Co. has begun the construction of another large building adjoining the present factory buildings, in order to enlarge the various departments sufficiently to meet the needs of the increased output for 1916. It will have 25,000 sq. ft. of space and will be one story in height for the present, but the foundation and walls will be heavy and it will probably be increased to five floors later on, as the space is needed.

This company will produce 20,000 cars this year, which means an increase of more than 100 per cent over the output of 1915. Last year the increase was from 2000 to 8000. At the present time the factory is turning out fifty machines per day and through February it will complete 100 machines per day.

National Acme Capital Now $9,000,000

CLEVELAND, OHIO, Jan. 30—At the annual meeting of the National Acme Mfg. Co. Thursday the stockholders authorized an increase of capital stock from $2,500,000 to $9,000,000. Of the new stock $1,500,000 is 6 per cent preferred, while the remainder is common. The Cleveland Trust Co. purchased the entire block of preferred stock and disposed of it in a very short time at 102 to local investors. This stock is to be retired in ten equal installments of $150,000 each, beginning Jan. 1, 1917. A sinking fund will be established and the redemption price has been fixed at 103, or the entire issue may be called in at any time on proper notice at 105. President Alexander said that a substantial stock dividend will be announced later.

The stockholders formally authorized the purchase of the property and business of the Windsor Machine Co., Windsor, Vt., the consideration being $3,575,000. This company has been one of the strongest competitors of the local company and last year paid large dividends to its stockholders, who realized a handsome price in the deal just closed. The Windsor plant will be operated under its present management and its principal output will be single and multiple spindle screw machines.

New Igniter for Fords to Be Made

DETROIT, MICH., Jan. 29—The Detroit Engineering Products Co., with a plant in South Bend, Ind., and the selling end of the business here in Detroit, was incorporated this week, the capital stock being $60,000. Among those interested in this concern which will make a new ignition system for Ford cars, are Earle Welborn, now assistant to Henry B. Joy, president of the Packard Motor Car Co., and formerly commercial car manager of the Dayton Engineering Laboratories Co.; Austin F. Bement, formerly advertising manager of the Electric Auto-Lite Co., Toledo, and now in charge of the national headquarters of the Lincoln Highway Association, Detroit; Charles A. Mattison, formerly of South Bend, Ind., an accessory salesman of many years of successful experience, who will be in charge of the active management.

The new product or rather the first of several new products will be an ignition system for Ford cars, utilizing the current from the Ford magneto and breaking it in such a manner, it is claimed, as to give the same effect as though a high tension magneto had been installed on the car.

Allen to Manufacture Pressure System for Garages

NEW YORK CITY, Jan. 30—Wm. A. Allen, head of the Allen Auto Specialty Co., has formed the Allen Pressure System Co., with a capital of $10,000, to produce gasoline and oil-storage equipment for garages. Mr. Allen's latest product is called the Apsco system and is applicable in the pumping of gasoline or other liquids on any floor of a garage by means of pressure. This means that by leading pipes from the main tank under the garage to any part of the building, gasoline or any other fuel may be had at any time.

95,000 Cars for Minnesota

MINNEAPOLIS, MINN., Jan. 31—Hennepin county leads in Minnesota for automobile registrations, with a total of 14,111. The second county is the one in which this city is situated, with 6135. The county of which Duluth is the seat, St. Louis, has 2747 cars. The Secretary of State estimates there are 95,000 cars in the State with the close of the old year, or nearly 40 per cent gain over 1914 when there were 68,500 cars registered.

74,123 Cars Registered in Kansas

KANSAS CITY, MO., Jan. 29—Final figures for the car and truck registration in the State of Kansas for 1915 show a total of 74,123, of which about 4000 are trucks, and 8260 motorcycles. This means there is a car for practically every fourth family in the State. The licenses for these cars turned $331,812.75 into the road funds of the counties.

Brazilian Exports Increase

NEW YORK CITY, Jan. 31—R. S. Noxon, manager R. G. Dun & Co., Rio de Janeiro, considers that Brazil at present has considerable prosperity in certain lines of business. He states that during the severe trade depression of the past two or three years—a depression contributed to by a certain degree of overtrading, by financial stringency, by the fall in the price of the two great exports, coffee and rubber, and, lastly, by the effects on Brazil of the European war—the commercial houses of Rio de Janeiro have shown a remarkable power of resistance against such unfavorable forces, and have withstood the severe strain in a most praiseworthy manner. Although weakness has resulted in some cases, for the most part the importing houses have consolidated their positions by reducing stocks, husbanding their resources, and restricting credits throughout the interior both in regard to amounts and time. These houses now give evidence of a very pronounced degree of solvency.

Official statistics of the exports of Brazil during the first ten months of 1915, as compared with the same period of 1914, show certain increases and decreases in total value. The exports of cotton declined $7,725,000; of rubber, $1,520,000, and of tobacco, $2,950,000. These declines, however, were more than offset by the following increases: sugar, $2,310,000; cocoa, $4,800,000; coffee, $17,675,000; hides, $4,320,000; yerba matte, $1,040,000 and pelts, $680,000. The total net increase in the value of exportations during the first ten months of 1915, as compared with a similar period in the preceding year, was $18,735,000. The total value of exports during the first ten months of 1915 was $209,235,000.

The importations of merchandise during the above ten months aggregated $124,905,000 in value, therefore, the favorable trade balance that Brazil has accumulated in the above period amounts to nearly $85,000,000.

Rock Island Plow Buys Heider Mfg. Co.

ROCK ISLAND, ILL., Jan. 31—The Rock Island Plow Co. closed a deal this week by which it secures control of the Heider Mfg. Co. of Carroll, Iowa, including the Heider tractor and all rights connected with the patent and manufacture. The special machinery, patterns, templets, and all raw material owned by the Heider company is now being shipped to Rock Island. H. J. Heider, the designer and inventor, will be retained by the Rock Island company, and he and a number of his employees will remove to Rock Island and be placed in charge of the construction of this machine at the Rock Island plant. The Heider tractor was invented seven years ago, develops 10 hp. at the drawbar, sufficient to pull three 14-in. plows in any soil, and can haul two to three farm wagons to market. The tractor develops 20 hp. at the pulley, enabling it to run a threshing machine or other work designed for a 20-hp. gasoline engine. The Rock Island company marketed the Heider tractor last year in a jobbing way and largely oversold the output of the plant. The Carroll plant was handicapped by lack of space, shipping facilities and skilled labor, and a proposition to merge into the Rock Island company was favorably received.

Velie Ships Trucks to France

MOLINE, ILL., Jan. 30—The Velie company this week shipped forty car loads of auto trucks to New York, for Havre, France, the largest single shipment of the kind ever made from this territory. A special train was required. The value of the consignment was $155,000. The company is maintaining a service station at Havre, in charge of James Gillespie, formerly connected with the Moline plant. A number of mechanics were sent abroad to be utilized in assembling the various parts. The Velie company reports an increase of 400 per cent in December business, as compared with the same month in 1914, due to a large extent to the war orders, although domestic consumption has also greatly increased.

Body Plant for Lansing

LANSING, MICH., Jan. 28—The Gier Pressed Steel Co., which will place on the market a new one-piece metal car body, has contracted for the erection of a new factory building, 160 by 600 ft. which will be one of the largest body making plants in the country. The company will spend at least $150,000, it is said, on the new building and its equipment. There will be several new presses, one of which specially constructed for the Gier concern, will cost between $18,000 and $20,000. Provisions have been made for a large increase in the production of light sheet metal products which have contributed in making the concern. During the past year the business increased nearly 150 per cent over that of 1914, and the orders now on hand are at the rate or on a basis of nearly double the business of 1915.

Addition Made by Standard Motor Truck

DETROIT, MICH., Jan. 31—An addition three stories high will be put up by the Standard Motor Truck Co. which will provide 60,000 sq. ft. of additional floorspace. Business during 1915 was more than double that of the preceding year.

Rochester to Have Radiator Plant

ROCHESTER, N. Y., Jan. 31—With a capitalization of $200,000, papers for the Unitube Auto Radiator Corporation have been filed with the County Clerk. The company will occupy the building in University Avenue formerly used by the Jenkins Motor Co., and will manufacture a new type of radiator. The directors are: C. S. Cook, Fairport; H. F. Beardslee, E. M. Sparlin and D. S. Crawford, all of Rochester.

Factory Miscellany

Hall Lamp to Add—The C. M. Hall Lamp Co., Detroit, Mich., maker of automobile lamps, has increased its capital from $150,000 to $300,000. An addition to its factory is in course of erection.

Knapp Adds—The A. C. Knapp Co., automobile top builder, Mt. Elliott Avenue, Detroit, Mich., has arranged for the erection of a one-story addition to the plant which will almost double its present floor space.

Murphy Brass Specialties Co. to Move—The G. W. J. Murphy Co., Merrimac, Mass., maker of brass automobile specialties, will remove to Amesbury and occupy a plant on Carriage Hill, where 200 men will be employed.

Hoover Ball Adds—The Hoover Steel Ball Co., Ann Arbor, Mich., has let contracts for additions to its forge and tempering department and to its grinding department, and will also build an office building, all of concrete and brick.

Price Electric Devices to Build—The Price Electric Devices Corp., Waynesboro, Va., will establish a plant at Basic, Va., for the manufacture of lighting and ignition generators, starting motors and other automobile equipment. E. L. Eakle is general manager.

Detroit Parts Co. to Build.—The Turner & Moore Mfg. Co., Detroit, Mich., which makes automobile parts, has contracted for the erection of a factory building, 75 by 300 ft., on Addison Street, between Junction and McKinstry Avenues, near the M. C. R. R.

Gilmer Completes First Unit—The L. H. Gilmer Co., Philadelphia, Pa., maker of belts, has completed the first unit of its new factory and moved its office and manufacturing departments to the new site in Tacony, Philadelphia. It is arranging to break ground immediately for a second unit to be 50 by 200 ft.

Columbia Truck Starts New Plant—The banks in Pontiac, Mich., are now offering for sale $100 6 per cent debenture certificates to the amount of $6,500, which is the amount guaranteed as a loan to the Columbia Motor Truck Co., when this concern decided to move from Kalamazoo to that city. The raising of the money is now necessary as the real estate has been purchased and the new plant's steel works erected.

To Make Bumpers—The Booth Bumper Co., 1714 North Twelfth Street, Toledo, Ohio, has been incorporated by W. S. Booth, G. E. Smith and F. H. Greer. The authorized capital stock is $10,000. The purpose of the concern is to make wooden bumpers for automobiles after a patented design for which Mr. Booth is sponsor. A plant will be erected.

To Make Bodies—Enlargement of the scope of the business has been decided upon by the directors of the Excelsior Seat Co., Columbus, Ohio. For many years it has been engaged in the manufacture of seats and bodies for horse-drawn vehicles. Now it will add automobile bodies to the line. The special machinery is being bought and is to be installed at once.

Detroit Twist Drill Doubles Capacity—The large additions to the plant of the Detroit Twist Drill Co., 634 West Fort Street, Detroit, Mich., was completed Feb. 1. Beginning that date, the production of the company was doubled.

The Week in the Industry

Torrey Detroiter Assistant Sales Mgr—Alfred O. Dunk, president of the Detroiter Motor Car Co., this city, announces the appointment of D. H. Torrey as assistant sales manager of his company, the appointment effective at once.

—

Dealer

Denby Salesmanship Course Winner—The Denby Motor Truck Co., Detroit, Mich., has awarded first prize to A. W. Boulden, Seattle, Wash. The award is the first in a series of monthly contests to extend over the year covered by a course of instruction in salesmanship and truck operation furnished free to owners and their employees of that company.

Trade Items from Minneapolis—The Northwestern Automobile Co. began this week construction of a $75,000 service and sales building. It is to be two stories with full basement.

The Whitcomb-Littlewood Auto Co., 30 Eighth Street N., has been formed to handle the Davis car by J. C. Littlewood, formerly sales manager for the Winton Co. branch here, and F. B. Whitcomb, for 30 years in the hay and feed business. Mr. Littlewood for 8 years was district representative and branch manager with the F. B. Stearns Co.

L. E. Rice of Cedar Falls, Iowa, has been transferred to take charge of the new branch of the American Tire & Rubber Co. at 41 Eleventh Street S.

Atlanta Trade Items—The new building of the Goodyear Tire & Rubber Co., Peachtree Street just north of Baker, Atlanta, Ga., is nearing completion and will be ready for the occupancy of the concern within the next few days. J. T. Taylor, manager of the Atlanta branch, is completing preparations to remove his stock and equipment as soon as the new building is turned over to him.

That the Reo company is negotiating for a site for a plant at this city is a rumor which has created a great deal of interest in automobile circles of the city. It is stated that representatives of the concern have held a number of conferences with local real estate men within the past few days with a view of securing information as to the possibility of purchasing a suitable factory site here.

R. N. Matin, general manager of the Oakland Southern Co., announces that his headquarters will be removed from 45 Auburn Avenue to 453 Peachtree Street. The retail sales of Oakland are to be handled by Boykin and Gilbert from the same Peachtree location.

Motor Men in New Roles

Beck Leaves Chicago Chalmers—G. V. Beck has resigned as district sales manager in Chicago, Ill., for the Chalmers Motor Co., Detroit, Mich.

James Keys Ring V.-P.—L. S. James, formerly manager of the Hood Tire Co. of St. Louis, has become vice-president and sales manager of the Keys Piston Ring Co. of that city.

Ferwin New York Oil Rep.—H. S. Ferwin has been appointed representative in eastern Washington for the New York Lubricating Oil Co., with headquarters in Spokane, Wash.

Porter Heads Braender Branch—The Braender Rubber & Tire Co., Rutherford, N. J., has opened a new branch in Philadelphia, Pa., at 1327 Race Street, in charge of W. L. Porter.

Gartley Maxwell Rep.—P. C. Gartley of the Maxwell Motors Corp. is now located in Seattle, Wash., and will act as factory representative and cover the States of Washington and Idaho.

Smith Lee Tire Superintendent—F. H. Smith, formerly with the Federal Rubber Co., Milwaukee, succeeded A. J. Pennington recently as superintendent of the Lee Tire and Rubber Co., Spring Mill, Pa.

Weaver Goes to Sun—H. G. Weaver, formerly sales manager of the Newell Motor Car Co. of St. Louis, has been appointed assistant general sales manager of the Sun Motor Car Co. of Elkhart, Ill.

Conn Joins Cassidy—C. F. Conn, well known throughout the automobile accessory trade in northern and central New York, on Feb. 1 became associated with the Edward A. Cassidy Co., Inc., sales managers for the Long Horn G-P Muffler cut-out and Cassco engine-driven tire pump.

Parsons Takes on Stutz—The Washington state distributing agency for the Stutz car has been taken by J. W. (Jim) Parsons, well known automobile racer, and his brother, G. M. Parsons, who have established headquarters in Seattle under the name of the Stutz Motor Car Co. of Washington.

McKay Back on Seattle Row—W. O. McKay is again on the Seattle automobile row, during the past week having assumed the management of the Newton Foster Co., distributor of Paige and National cars. Mr. McKay some four years ago was managing partner of the Thomas-McKay Co., distributor of the Locomobile.

Whittaker Dyneto European Rep.—Benjamin Whittaker has been appointed European representative of the Dyneto Electric Co., Syracuse, N. Y. His headquarters are at 2 Norfolk Street, Strand, London, W. C.

—

Dealer

Continental Motor Truck Opens Office—The Continental Motor Truck Co., Detroit, Mich., has opened an export office at 17 Battery Place, New York City.

Represent Acme Die Castings—Weidermiller and Ewald, Detroit accessory sales agents, are distributors for the States of Michigan and Ohio for the Acme Die Castings Corp., Brooklyn, N. Y.

Hodgman Rubber Offices Moved—The Hodgman Rubber Co. has moved its general offices, located at 806 Broadway, New York City, to Tuckahoe, N. Y., where its factory is located. The New York sales offices are at 8 West Fortieth Street.

Denver Trade Happenings—Tom Botterill, 1272-1278 Broadway, Denver, distributor for the Pierce, Hudson and Dodge in a large section of the mountain territory, has planned a new building for increased serve. It will be 50 by 125 ft. He will extend from his present building the remainder of the block over to Lincoln Street.

Ford's Wis. Convention March 1—Although the new Milwaukee plant of the Ford Motor Co. opened for business on Thursday, Jan. 27, the formal and official opening has been scheduled for March 1, when Henry Ford will come to Milwaukee. On this occasion all Ford dealers in Wisconsin will be invited to a convention. It is stated that the entire output will be for Wisconsin distribution only.

Milwaukee Changes—The Hoppe-Hatter Motor Co., 543 Broadway, Milwaukee, has been appointed city agent for the Buick in Milwaukee. The appointment is a new departure, the Milwaukee branch of the Buick Motor Co., 160 Wisconsin Street, having handled retail business in the city of Milwaukee since its establishment. G. G. Lund has been appointed agent for Wauwatosa and other suburban points in Milwaukee county. The Hoppe-Hatter Co., long agent for the Rauch & Lang-Baker electric, has also been appointed distributor of Owen Magnetic cars.

Hudson Super-Six

Eights and Twelves Defeated by a Six

THE facts about the Super-Six seem almost like fiction.

Think of increasing motor efficiency 80 per cent at one jump without adding size or cylinders.

Think of a small light Six—cylinders 3½ x 5—developing 76 horsepower.

Think of that Six, in official tests, breaking all stock-car records.

Think of a simple, light-weight Six outmatching Eights and Twelves.

And think of a $1375 car proving itself, beyond possible question, the best performing car of the day.

MEN WILL HAVE THAT 80%

This motor's capacity is 288 cubic inches. The best former motors in that size delivered about 42 horsepower. The Super-Six delivers 76 horsepower.

Any motor which shows about half that efficiency will have no attraction now.

This extra 80 per cent means more than added reserve power. It comes through ending vibration. All this super-efficiency comes through saving power which former motors wasted within themselves.

So it means vast economy. It means such smoothness as you never have known before. It means matchless flexibility. It means, as shown by official tests, record quick response.

Every quality men prize in a motor has been bettered vastly in this Super-Six.

EXCLUSIVELY HUDSON

Now, for the first time, a premier attraction is found in one car only.

The Super-Six is a Hudson invention controlled by Hudson patents. So no other car will have it. And any like performance is impossible without it.

Eights and Twelves of the finest types have been utterly defeated. Every reason for a double motor, with its extra weight, has vanished. Not a Six of the old type has any chance in comparison.

So this invention gives the palm to Hudson, over all cars in the field. One ride in the Super-Six will convince you of that.

$42,000,000 OUTPUT

We have doubled our factory because of this invention. And we shall build this season $42,000,000 worth of these Super-Sixes.

They come equipped with most luxurious bodies. All that we save by this doubled production has gone into extra elegance.

So the Super-Six will stand supreme both in motor and in looks. Any Hudson dealer stands ready to prove that to your fullest satisfaction.

Cash in

—on the demand for Stewart products Hundreds of car owners in your vicinity see and read Stewart advertising. They want Stewart Products—are going to get Stewart Products—will insist upon Stewart Products. The only question is —are *you* going to be the one to make the profits by cashing in on this Stewart demand?

You don't have to "push" Stewart Products—they move easier than any accessories on the market—they are half sold to the public before they reach you.

Then why gamble with other goods, when you know Stewart Products are wanted?

Why risk your reputation in handling inferior goods when you know the demand is for Stewart Products?

Can be installed on any car—old or new

$10

Stewart Vacuum Gasoline System

Any dealer can put this system on any old car and thereby bring it up-to-date. It has put back into the running more old cars than any other feature ever offered the automobile public.

The Automobile

British armored cars at a depot in France

British Use Many Armored Cars

Varied Chassis With All Degrees of Armament Tried—How French Army Service Affects Trucks—Detail Design Could Be Stronger

By W. F. Bradley

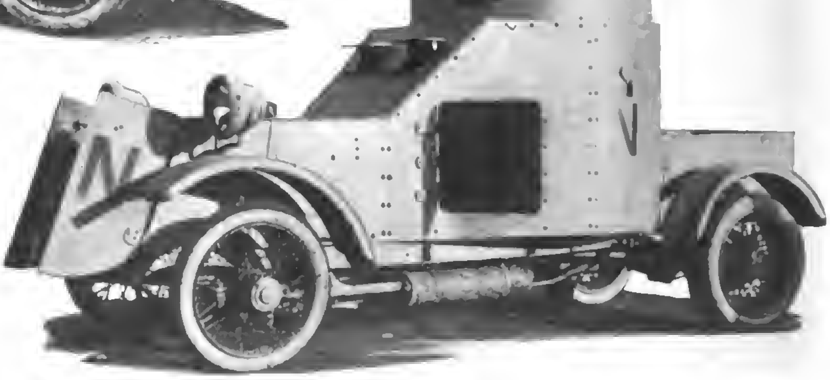
Special European Representative of The Automobile

THERE are few types of automobiles which have not been made to carry a gun or guns. The range varies from a motorcycle sidecar with a light machine gun, to a 5-ton truck with a marine weapon aboard. They all look good in maneuvers, and they all appear convincing on specially selected ground, but when they are submitted to the crucial test of war, there are some deceptions. There is no necessity to argue the value of automobile guns, for everybody is convinced on that point; the problem is to arrive at the most suitable type, or types, for it is obvious that one machine cannot meet all the varied conditions of war.

The motorcycle with a third wheel attached so as to make it possible to carry a gun and an extra passenger, has the advantage over the unmounted machine gun sections of greater speed and less visibility. They are of necessity limited to two men, who are a more difficult target than the half dozen in the unmounted sections. Their ability to operate away from made roads is not very much greater than that of a car, and under present conditions of trench warfare there is not great scope for them, for they cannot get into positions attainable by the man-carried guns. Probably owing to this, and to the fact that they cannot give the men the advantage of armor plating, they are not used to any great extent by any belligerents in the field.

Every type of touring car, up to the 60-hp. semi-racer, has been made to carry a gun. In the early stages of the war numbers of ordinary touring cars were taken out of private service, equipped with a machine gun and sent to the front without any plating being added. It is hardly necessary to explain that such a machine could not go into an exposed position with any reasonable hope of returning in safety.

As soon as it was possible to do so, these cars were armor-plated, although not very effectively at first. It is a rather curious fact that when the war broke out no armored cars existed in the Allied armies, although Germany appears to have had some. On page 260 is a good example of one of the earliest armored cars to be put into service by the British. This is a standard Rolls-Royce, which had been used for touring purposes by the officer in charge of it. A louvred guard was built in front of the radiator; a steel windscreen replaced the usual glass appliance, and a machine gun was mounted in the tonneau in such a position that it could be raised above the pointed steel stern. By crouching low, the



Left—A familiar type of armored car used by the Royal navy in France

Below—One of the earliest types of armored cars to be used in France. It has a Rolls-Royce touring chassis

driver and gunner could get a certain amount of protection, but there was always a certain amount of danger of the driver being winged. In this car no attempt was made to protect the tires or the motor. Although this type of car did good service in the hands of a daring crew, it would not be considered a safe or up-to-date machine at the present.

A further development is shown on page 261. This is also a Rolls-Royce chassis, but unlike the earlier car, is completely armor-plated, the side panels being flush with the outside of the wheels and the upper portion of the body being the frustrum of a pyramid. The upper base of the frustrum is hinged so as to allow a machine gun to be raised above the top of the body, and there are hinged doors in the sides of the pyramid. Two hinged panels are carried in front of the radiator, and capable of being opened or closed from the driver's seat. With this amount of plating it became necessary to fit twin pneumatic tires on the rear wheels. It is worth noting that no armored car has been able to work successfully with single pneumatics on the rear wheels. Some protection is given front tires by steel fenders which tend to deflect bullets. This type of car trails a special gun carriage and a naval gun, the carriage having automobile-type wheels and twin tires. This is a development of particular interest. An automobile of this type is quite capable of dealing with the extra load.

Four Cylinders Adequate

Most high-grade automobiles with four-cylinder motors of 4 by 6 in. bore and stroke, or the equivalent, have proved satisfactory for armored-car work. With an adequate front radiator and good capacity pump overheating troubles are not experienced, despite the plating. Many cars have gone into service without other mechanical modifications than the reducing of the gear ratio; double steering is a refinement, though not always adopted. Armament generally consists of a machine gun, and sometimes of a 1-in. gun in addition, mounted in a turret and capable of being fired without the gunners exposing themselves. Best results have been obtained when these cars have worked together in squadrons.

It was to be expected that attempts would be made to use comparatively heavy guns on automobile chassis. In the early stage of the war the London motorbus B-type chassis was made to carry a powerful naval gun, the car being without any armor plating. This experiment was a failure, the springs being unable to withstand the recoil of the gun. It is doubtful if any other bus or truck chassis would have proved any better.

Probably the only really successful use of an automobile for carrying a field gun is the special De Dion Bouton chassis with the famous 75-mm. gun. The chassis approximates the firm's 3-ton truck model, but the feature is the system of jacks allowing the entire load to be taken off the springs, and giving the vehicle the same amount of rigidity as the ordinary gun chassis. This is a type of automobile developed before the war and used very extensively and very successfully at the present time. These cars carry sufficient armor plating to protect the crews against rifle bullets, and each gun car is served by 3-ton trucks carrying ammunition. These ammunition cars have armor plating for the motor and have the gasoline tank set within a steel box between the rear of the frame members. Thus the tank is incased on all sides and along the bottom, while the body prevents it being hit from above. No armor plating is used for other parts of the truck.

On certain portions of the front numerous Pierce 5-ton trucks, with heavy armor plating are fitted with anti-aircraft and other types of guns. One disadvantage experienced with heavy armor plating is the extreme rigidity imparted to the chassis. It appears necessary to secure a method of attachment which will allow the chassis to maintain the degree of flexibility for which it was originally designed.

Green drivers are not the only enemies of the automobile. Many engineers and experts in various branches of military operations when allowed to apply their special knowledge to the automobiles can ruin a car before it ever goes into service. Naval engineers, for instance, have a lot to do with armored automobiles and almost invariably fail to realize that weight is an important factor on the road. This is doubtless due to the fact that aboard ship they are not usually restricted in any way by considerations of weight.

Overloading Common

There was a good example of failure to appreciate this important factor in two special armored cars which were sent from England to France, recently, for experiments at the front. The standard Pierce-Arrow 5-ton chassis had been transformed into an armored car to carry a 6-pounder gun. Each chassis was fitted with a big bed plate, about 4 ft. 6 in. in length, the full width of the frame, and 1 in. deep. Under this was a very heavy structure of I-beams, placed about 1 ft. apart, and below this another heavy bed plate, similar to the upper one. It was intended that when the gun car had taken up a suitable position big wooden, metal-faced wedges should be driven between the lower bed plate and the ground, thus providing an absolutely rigid mounting for the gun, and of course relieving the car springs of any reaction. In this car the interesting feature for the automobile engineer is that the naval officers appeared to have failed to realize that they were piling up weight in an extraordinary manner. The armor plating weighed between 3½ and 4 tons, the mounting 2½ tons, the gun about the same; the weight of ammunition, stores, supplies and accessories, is not known. But when the truck was put on the scales, without its full equipment, it was found to weigh more than 12 tons.

Under such conditions it was to be expected that there would be trouble from the first. All the springs flattened; one of the cars had a ¼-in. twist in every universal coupling back of the transmission, and the main shaft was sprung ⅛ in., so that it was impossible to move first or reverse without a heavy hammer. It is surprising there were no broken teeth in the transmission or rear end. Before the car could go into service it was necessary to hack away a lot of metal which at one time had been considered necessary and to reduce the weight to a reasonable quantity.

Trucks Need Protection

The most obvious defect of automobile trucks put into military service is the lack of protection against collision. In many of the repair shops at the front about 50 per cent of the truck casualties are caused by trucks bumping into the machine ahead, when operating in convoy formation. Usually the officer in charge precedes the convoy in a light touring car, and unless he is a really experienced man he will set up too fast a pace. Each driver tries to keep as close as possible to the man ahead, with the result that when a sudden stop has to be made radiators are smashed in and sometimes damage is done as far back as the third cylinder.

It is not every officer who is capable of handling a big convoy in a satisfactory manner—maintaining a reasonable average, insisting on the regulation space between each truck, and at the same time being prepared if any man falls out owing to mechanical trouble. The officer who knows his business puts a skilled driver on No. 1 truck—a man who can differentiate between 12 and 14 m.p.h.—and a good mechanic on the last unit of the convoy. As it is forbidden to pass the truck ahead, the correct average can be relied on whether the officer remains in front or falls behind; if there is a breakdown the last man is often able in a few minutes to give assistance which will save hours.

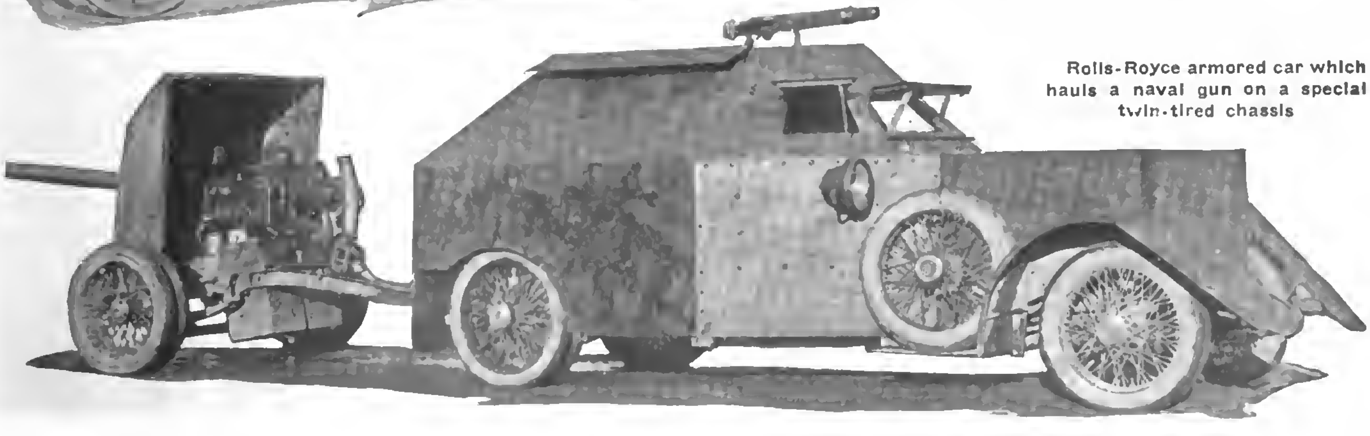
American Trucks Protected

Some of the American trucks sent into France looked as if they had all the radiator protection that could be desired. Packards, for instance, have a very substantial buffer, and the Pierce trucks are also well protected. But for present army conditions even these good examples are ineffective. It has now become the practice to fit locomotive-type spring buffers front and rear on all trucks going into active service in France. Velie trucks, which are among the latest to be adopted by the French army, have a most formidable set of buffers and bars set out a couple of feet in front of the radiator. It consists of a very heavy steel gate, the full height of the radiator, with powerful coil springs back of it. In order to crank, or indeed to get near the radiator, the gate has to be opened; it is on hinges for this purpose. The officers here maintain that they need all this protection. The type of guard on the level of the frame members, as fitted to Packards and a few others, is generally useless, for the regulation army body has a rear overhang which will pass above the guard into the center of the radiator.

Some time ago White trucks were fitted with a stout steel bar carried in hangers rivetted to and projecting from the front of the frame members. The bar was ahead of everything and a few inches above the bottom of the radiator. This was not found to be sufficiently effective and now the bumper is an I-section steel member, as heavy as the frame members, placed level with the middle of the radiator. At the rear of the truck is a lighter transverse bumper, with coil springs back of it, placed at exactly the same height as the front bumper. In case of collision the two bumpers come together. It should be pointed out that these safeguards are not necessary for ordinary commercial service; they were not even found necessary in the army tests prior to the war, for then skilled drivers were always employed.

Generally solid tires on trucks working in the North of France do not average more than 5000 miles. This figure is obtained from records of trucks using tires of a size considered adequate in civilian service. The shorter life is due to the more strenuous conditions under which the trucks have to operate. No matter how good the service, there is always a certain amount of speeding; English drivers are as great sinners in this respect as the French. In the northern parts of France most of the roads are granite paved, with a macadam or dirt strip at each side. When traffic is heavy the right-hand wheels are constantly slipping from the paved portion to the dirt strip, and back again, this series of jumps causing the tires to chip away laterally. Sections of the tire also loosen from the

London omnibus B type chassis carrying a naval gun

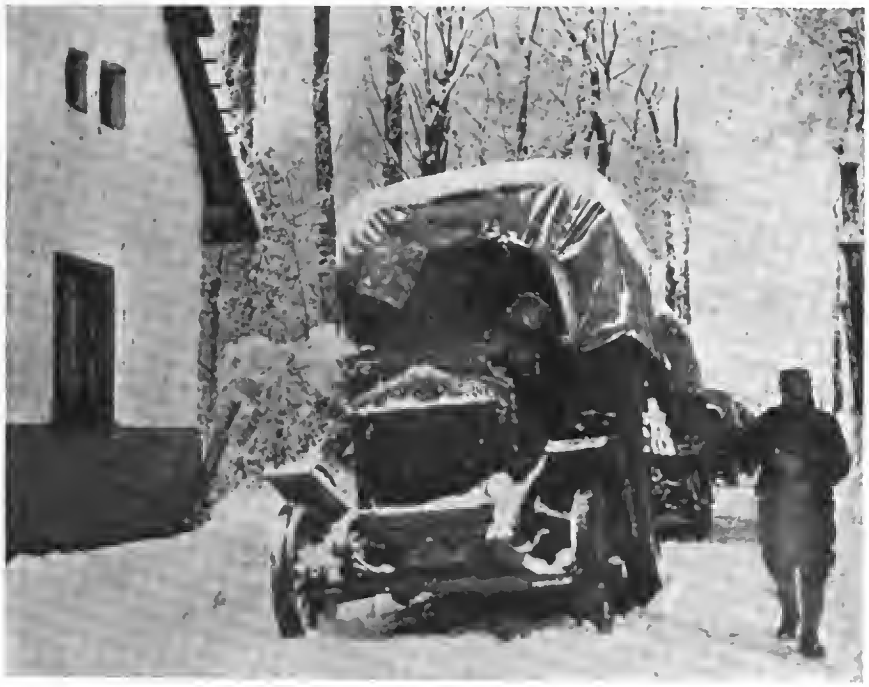


Rolls-Royce armored car which hauls a naval gun on a special twin-tired chassis

rim, and when there has been a loosening up in two or three places the whole tire is liable to come away. This appears to be due to bouncing of the wheel on the road; when driving fast the wheel strikes the ground at intervals with considerable force, and these repeated blows loosen the rubber from the base. It is found that this is more common with front than with rear wheels.

Another source of tire trouble, which was known to users before the war, but has become more accentuated since, is due to arched roads. It is obvious that with a truck running on one side of a highly crowned road the full width of the tread cannot be in contact with the road surface, and the wider the tire the smaller the proportion in contact. This throws an excessive load on one portion of the tire, or on the inner tire when duals are used, and causes rapid wear. The evil is lessened on those trucks having chain drive with slightly toed-in wheels, as is common with the front wheels of automobiles.

This evil has been recognized for a long time and attempts have been made to construct a type of transmission allowing the wheels to accommodate themselves to the arch of the road. Also the latest road engineering practice is to make road surfaces as flat as possible consistent with drainage. The war has only served to emphasize the need for attention to this matter. Where worm, bevel, internal drive, and chain drive trucks are working together it has been possible to make interesting comparisons on this question of tire wear.



Pierce-Arrow trucks working under winter conditions

War's Severe Test

The war is proving more strenuous than the severe tests to which some of the manufacturers submit their trucks at home. As an instance, a high-grade American worm-drive truck is giving trouble owing to the breakage of differential housings. This is a good truck, which before being put on the market was given a very thorough try-out in the Middle West and the West, without any defects being revealed. However, the roughly paved roads of Northern France, together doubtless with some overloading and some speeding, are causing the housings to crack, and the maker is replacing them free of cost. Closely examined, this is found to be a case of faulty design, but is a fault which American dirt roads and cross-country conditions could not reveal and which required the abuse of war service to bring it out.

Many Parts Fail

There have been some other cases of axle housings failing, but these have been traced to a heavy load shifting to the right-hand side of the truck. Loads of shells are particularly liable to slip in this way, and as the right-hand side gets much more pounding than the left, it is not surprising that axles sometimes fail.

Manufacturers all over the world who had old models or units in stock have been tempted to get rid of them in the various armies. These cases are now coming to light. One high-class firm used a certain number of touring car crankcases in order to finish a series. These were too weak for truck service, with the result that all the front hangers snapped and the French repair shops have had to fit these trucks with a steel member forming a brace under the front end of the crankcase. The policy of this company cannot be considered a wise one. Had it been a French company of equal standing, there would have been plenty of people to excuse or explain away the incident, as some French firms have so many interested boosters that the knockers are never heard. But being an American firm the bare statement goes round that X— crankcase hangers break off. There is nobody to explain, and X—, who makes one of the best trucks in America, is apt to be rated with the firm making one of the worst.

All American manufacturers are at a disadvantage owing to the absence of really skilled men, or men with lengthy experience of their particular make. At home real service is given users, and every manufacturer is interested in seeing that the user of his truck is getting the best out of them. In the war zone there can be no real service, and even if the service man were on the spot he would not be allowed to follow up his own trucks. One case with which I am acquainted is interesting. Pierce-Arrow has about thirty 5-ton trucks in armored car service in Northern France. This is the most strenuous service on the front, for half the cars are overloaded all the time, and all of them have to operate very close to the German trenches. This fleet is in charge of an officer who knows all there is to be known about Pierce trucks and who gives them all the attention that could be obtained from a service man at home. The result is that at the end of six months' active service in France, preceded by several months' service in England, not a single order has been sent in to the permanent store department. The only consumable stores that have been used are brake liners, lock washers, carbureter floats and needles, rear lamps, etc. Two men, one of whom is only a driver, are sufficient to attend to all the repair work.

In the same battery ten mechanics are required to keep the officers' touring cars and the despatch riders' motorbicycles in proper order. In other sections of the army, operating in the same district, constant reports are being received of burned out bearings on Pierce trucks. Inquiry has shown that in every case this is due to the use of unsuitable, though not poor quality, lubricating oil for this type of motor.

Carbureter Adjustments Needed

Carburter settings found right in America are very rarely satisfactory here, owing to the different grade of gasoline used and changed climatic conditions. If the trucks pass

A row of White trucks with a type of radiator guard that was insufficiently strong

through the hands of a tester in Europe, this trouble is considerably diminished; yet there are hundreds of American trucks operating extravagantly in Europe owing to lack of carbureter adjustment. As a general rule American trucks have bigger motors and will do a lot more top gear work than those of European construction, but much of this advantage is lost owing to indifferent carbureter settings.

Magnetos Last Six Months

One important repair depot finds that magnetos cannot be relied on for more than six months' average under war conditions. At the end of that time they have lost much of their magnetism and various screws have begun to work loose. The repair depot in question finds it necessary to remove and carefully examine all truck magnetos every six months. The same trouble has been observed at various times on visits to touring car repair depots, but this case of the trucks is the only one on which really reliable data has been obtainable.

Carbureter Needles Wear

There is an unusual wear of carbureter needles attributed to the presence of very fine sand in the gasoline.

The complaint is heard that differential locks are not sufficiently used; under present conditions they are more than a luxury.

Self-starters are not appreciated. They are to be found on one make of truck used by the French, but they are very rarely in a condition to be used. More often than not the batteries are requisitioned to light a dug-out, or some under officer takes them to light his own quarters. Some of the mechanical transport sections use enormous quantities of dry batteries, but the current is used for lighting the men's quarters and dug outs and not for exploding charges in the motor cylinders.

Want Simpler Control

As army regulations call for two drivers on each truck, a self-starter is certainly a luxury. Controls should be simplified for military service. With two ignitions, spark and throttle levers, extra air lever, electric light, electric self-starter, and gasoline and lubricating oil gages, there is enough to keep the average green driver worried for at least twelve months. At least one truck has the whole of this equipment. The ideal is fixed ignition, with magneto only, and accelerator pedal. A lever on the dash should regulate minimum throttle opening and cut off the ignition when fully closed. The use of a motor governor is preferable; European manufacturers had little use for the governor before the war, but they have changed their views since.

Disembarking at Salonika

"The man who is driving an ammunition truck at the front has got the least satisfactory job in the whole army," declares an automobile agent who has been serving as a private in the infantry since the beginning of the war, and was present at the great Champagne battle last September.

Trucks Run to Firing Line

"There is an impression that automobile driving is the soft job of the war, but as a practical motorist I would much rather be serving in the trenches than at the wheel of a truck. The number of shells which had to be fired by each gun prior to the infantry attack in Champagne was really prodigious. Thousands of American trucks were running day and night, taking shells right up to the gun positions, for the old method of transferring to horse teams has long been abandoned. Generally the guns are in positions away from the main roads, but special tracks are made so that the automobile trucks can go right up to them. The ammunition is unloaded and placed in underground shelters within easy reach of the battery. Naturally the enemy keeps a close watch for the ammunition columns and shells them whenever possible. If an enemy's shell strikes an ammunition truck there is not much left of either truck or men. In the big attack a certain number of American trucks were blown up in this way.

Truck Drivers Hard Worked

"When a big offensive is in progress truck drivers are much harder worked than men in any other branch of the army. I met some drivers who for three weeks had not averaged more than four hours sleep out of each twenty-four. The call for ammunition was so great that they had to work prac-

Steam tractors are still used extensively

tically day and night. When off duty they slept in hammocks fitted up inside their trucks. Some of the men have displayed considerable ingenuity in making their trucks into comfortable living quarters. They strengthen the top, so as to make it absolutely waterproof and capable of supporting two hammocks, and they make the front and end panels of the body close fitting, so as to keep out all drafts. Hay in the hammocks is an additional comfort. The beds have to be arranged so that they can be put out of the way almost instantly and brought out as quickly. In rush times the men get their sleep in snatches, and it is a great convenience to be able to pull down the hammock, get into it and sleep by the roadside for an hour.

Straw Packed Radiators

"The men take the same care to keep their motors warm as to preserve themselves from the cold. Precautions have to be taken as a matter of safety as well as general convenience, for delay in getting away may be fatal. The most commonly adopted plan is to make two straw mats, such as are used by gardeners, one fitting closely round the motor hood and the other completely covering the radiator. An additional precaution is to drain the carbureter float chamber and leave a small kerosene lamp burning under the hood. In this way a truck can stay on the road all night and be easy to start in the morning. Water is not usually drained off, for there may be difficulty in getting a fresh supply, and anti-freezing solutions are not much in favor with the drivers.

The latest form of French Army Packard. Note substantial radiator guard

"Not only have truck drivers little opportunity for sleep, but they cannot count on meals with the same regularity as the infantry. During the Champagne attack drivers would often come into our quarters and beg food which they would take away with them to eat on the road. The men who are wise to the game make a point of always carrying reserve rations and a portable cooking stove. As there are two men on each truck at the front, one of them can look after the cooking arrangements while on the road or whenever a stop is made, and thus overcome the defects which are inevitable when men are moving about frequently and rapidly as required in this military work with its rapidly changing conditions.

General Gallieni, the new War Minister, is on a campaign against all favoritism and abuse of privileges. His activity has been drawn toward the automobile section of the army and very drastic measures have been taken in one particular case. An officer in the territorial army had taken as his orderly a soldier who was the private owner of an automobile, the officer and soldier making use of the car for their military duties. While there is nothing in the regulations specifically against this, the Minister of War considers it an abuse of the spirit of the law, for the fact that he owned a car gave the private soldier an advantage over his companions and the officer got the use of a non-military machine.

Punished for Using Own Car

As a punishment the officer has been condemned to sixty days imprisonment in a fortress and to the loss of his rank. If he is of military age he will still be eligible to serve as a private. The owner of the car has been ordered to take his place in the reserve depot and to be sent to the front with the first draft. This decision has been sent to all military commanders as an example.

In automobile circles there is some annoyance at the tendency of military authorities to look upon professional drivers and mechanics as shirkers. The purely military view is that any old man can be taught to handle a truck or a touring car and that the best place for young professional drivers is in the trenches. Thus men totally devoid of mechanical ability are being rough-hewn into drivers and men of twenty years road and factory experience are sitting behind a gun. One specific instance is that of Louis Wagner, twice Vanderbilt Cup winner, who until recently was serving as a private, while the truck driver attached to his regiment was a former village schoolmaster with one week's experience at the wheel. There is also a tendency for the professional military view regarding automobilists to be shared by the general public, with the result that automobile drivers are considered to be in less danger than men serving in other branches of the army. Because of this a large number of professional race drivers have asked for and obtained transfers to the flying corps. The men consider that they are in no more danger in the air than on the road, but they get credit for undertaking more difficult work.

Want Motorists to Drive

As a protest against the present system, a syndicate of automobile drivers and an association of automobile manufacturers at Lyons has written to the Minister of War and other public officials asking that all professional drivers and mechanics should be drafted at once into the army automobile service. The next set to be called up for automobile service should be those men who had once been professional drivers; following this drafts should be taken from private motorists holding the Government driving license, the men with the oldest licenses being called first.

The adoption of this plan would improve the automobile service of the French army and, besides this, would result in a marked economy in the operation of the military automobiles and motor trucks.

The Truth About Materials

All Metals Are Raised in Price, But Steel Supply Is Adequate—Rise Must Fall Partly on Consumer—Light Weight Design Encouraged—No Need for Alarm

IN a year the amount of steel that is being produced in America has doubled, and of this double output munitions of war consume but a moderate percentage. The doubled output is hardly enough to meet the demands of war and the immense demands of peaceful industry as well. Steel prices always have fluctuated with the normal alterations always taking place in demand and to-day, the demand being higher than ever before, the prices are likewise. But there is no *shortage*, there is no fear that any responsible manufacturer using steel in his business will have to curtail his output below what it was for last year, and there is little doubt that the automobile industry will be able to *increase* output to a marked degree.

In a broad and general way the attitude of the steel makers is that a regular customer can have his regular supply, the steel trade will stand back of the steel consumer whom he knows and trusts, but no consumer will be allowed to buy in excess of his real needs.

In two metals there is a real shortage, and means must be devised for doing with less of them in almost every class of service, these being aluminum and zinc, but slight changes in design render it possible to dispense with some aluminum and almost all brass, so the output of automobiles is not going to be held up on that account. Steel prices are unlikely to drop for some time to come, but the situation is easing in certain ways. For instance, there has been an immense amount of building done in 1915 and this is still in progress, but there are indications that the enlarging factories will soon have completed their growth for a time. Similarly, the railroads have needed much extra material in their attempts to combat the shortage of freight cars, and this will slack as the shipping situation eases, and it is beginning to ease perceptibly.

Cars May Cost More Temporarily

However, it is practically a certainty that all car manufacturers will have to raise the price of their machines for next year, or, if they do not do this and hold the prices where they are they will have to cut the quality. This is the unanimous opinion of men who are closest to the present condition of the materials market. In fact, there is no more important thing in the minds of automobile producers to-day than this question of price. There is no need for maintenance of present automobile prices, just as there was no need for the immense cuts made last summer. The demand for passenger cars and trucks is such that a rise in price sufficient to cover the rise in the cost of materials would hardly lose the industry a single order. To have the situation covered and more than covered it would not be necessary to raise prices of cars all the way back to what they were a year ago.

Three of the foremost companies have now raised the selling figure, Cadillac and Packard having done so some months ago, and Chalmers falling in line recently. Other concerns need have no fear in following this lead.

The general feeling is that all must meet the situation fairly and acknowledge that they cannot continue at present figures when it is costing them about one-fifth more to build the vehicles than it did a year ago, solely because they have to pay much more for the raw materials. Therefore, it can be stated positively that, unless some unforeseen and highly improbable easing-off of the demand for iron and steel, copper, zinc, aluminum, brass, bronze, tin, etc., takes place, the profit in the vehicles will not be sufficient to give a reasonable return on the money invested.

Supply and Demand

The whole situation is primarily a question of supply and demand. There is an over-demand for everything and this is immediately reflected in the price. Fortunate indeed is the far-sighted purchasing agent who looked ahead and contracted for his supplies well in advance, but there are a great number who did not anticipate the present condition and it is these that are in difficulties. Steel mills will not contract now for material for delivery before six months hence, and there are mills which are asking ten months. Heretofore it has been possible to secure contract material within thirty to sixty days at the longest. This will immediately make clear the predicament of the concern which is not well supplied with what it will need for another half year. Add this question of delivery to the problem of price, and you make a combination which is serious for the big manufacturer as well as the little fellow.

Assemblers Suffer Most

Investigation has shown that only in very few cases have the manufacturers been able to take care of their prospective needs beyond January, 1917. They cannot even make contracts at present prices to extend farther ahead than that time because the steel mills will not entertain them. This may change as the year advances, but at present no one will venture to say what conditions will be when another twelve months roll around.

Apparently the car assembler is hit the hardest—much more than the producer who makes the parts he puts into his chassis. The parts maker only gets materials as he contracts for his product, and hence he cannot buy material in large quantity very far ahead unless he is a very big parts maker and is able to figure on a general average from year to year. This condition immediately reflects on the price which the car builder has to pay, and any manufacturer to-day will say that he is paying more in proportion for everything he does not make in his own shops. This means simply that the assembler cannot make as much profit to-day on a car which he sells at the same, or even a slightly higher price, than the actual car manufacturer, even though both cars were identical in quality and design. This statement would be discounted somewhat where the assembler works on a very large scale and is in a position to contract for what he is reasonably sure he will need many months hence, but very few are in that enviable position.

Some of the strong car makers will not feel the present great increases in price before next January because their contracts were made at lower figures to run until that time, but after that date none will say what he will have to pay. Therefore, with the announcement of 1917 models, which will begin about the middle of the year if past policies are taken as a criterion, we will see increases all along the line unless some other way is found to surmount the situation.

Perhaps in some cases reduction of manufacturing cost can be made to offset the added cost of what goes into the cars, but this is very doubtful in view of the enormous increases. Then, too, the manufacturers, even though some of them are fixed until next January, will have to look ahead farther than that, because in most cases, they are simply getting nicely started on the new models by the first of the year.

Cost Up 20 Per Cent

For regular customers, the general advances in materials means at the present time an increased cost of about 20 per cent on every car turned out, all other manufacturing cost factors remaining the same. This takes into account all materials with which the automobile is concerned. It figures in the aluminum, copper tubing, wiring, etc.

To give a few specific instances of what this materials shortage—it can be called that—means, it might be said that the hot-rolled steel makers have increased prices nearly 100 per cent within a year. This takes in all sorts of bar stock which is a very important part of the car man's needs. Normally such material can be bought for $1.10 per 100 lb., but at present it is quoted at $2.00 and delivery is far in the future.

Manufactured steel is especially telling upon the automobile industry. This is the stock that is re-rolled and made into frames, and countless other parts. Small strips of this kind have advanced from $2.40 per hundred to $3.50 and $4, and frame strips have gone up almost $1 a hundred.

One prominent manufacturer with an output of some 15,000 cars yearly figures that the frame alone costs $4 more than it did last year, and this advance is proportionate throughout. Nor does the advance stop with the metals; on the contrary the leather and upholstery materials are up, too.

Effect on Parts Makers

What has been said regarding car makers applies with equal force to the manufacturers of component parts for cars. Needless to say, they cannot take contracts with a certainty of delivery at any specified time, nor will they take any new business without raising the price to meet the new conditions, and perhaps even discount further advances to a large extent.

The parts people are especially hard hit in cases where they have long time contracts to meet which were taken at prices based upon material costs far below present prices. Unless they were able to contract for what materials they needed, at prices in proportion to what they are getting for their products, they are simply taking the loss out of their expected profit. In many instances the parts concerns under contract have been to the manufacturers with the matter, but the car maker's answer is that he is in the same boat, and naturally looks to the parts man for that which he has planned.

This condition was well illustrated by a well-known carbureter maker of Detroit. He buys $12,000 worth of brass castings monthly and the cost has risen from 20 to 27 cents a pound, with an expected advance to 35 cents. He further uses $2,000 worth of brass rod each month, and on that the price has gone from 13 cents normally to 35 cents. Besides this, deliveries cannot be secured within four to five months, whereas in the past he has been accustomed to get what he wanted within two to three weeks.

Weight-Saving Design Forced on Engineers

As a result, this carbureter producer is like all others—he is trying to reduce the weight of his instrument by redesigning and shaving here and there without impairing the design. Necessity is dictating great things in the carbureter field, as in most others, for in another great carbureter plant in Detroit they are daily turning out 500 carbureters made of malleable iron instead of brass because the former is a cheaper material and seems to work equally as well. Some of the makers are even striving so to build their carbureters that some parts can be made of pressed steel, this reducing the cost.

So it goes down through the industry. You will see axle makers scratching their heads over problems of weight reduction; see them substituting certain constructions for others where they can save in material cost without hurting quality; you will see this thought uppermost in the minds of a great many engineers.

Position of the Automobile Industry

It is sometimes suggested that the industry should assert itself with the iron and steel makers, the aluminum producers and the rest. The assumption being that the industry takes such a large proportion of these products, that it should be able to *demand* deliveries when it wants them; in a word, it should by its united strength be able to bring the materials people down on their knees and bring about reasonable service.

Nothing could be more absurd. ***The combined tonnage of iron and steel used by the automobile industry is not over 5 per cent of the total production of the iron and steel industry of this country.*** Why should the iron and steel industry, then, have any particular regard for the automobile industry? The railroads, the structural steel users and the bridge builders are the big consumers, and their demands must come ahead of the automobile makers. This fact is recognized by a great many of the automobile men, but it is likewise overlooked by a great many.

The total consumption of steel last year by the automobile industry was not over 1,200,000 tons, whereas the production estimated for 1915 was about 24,000,000 tons. One has but to figure it out to see where the automobile industry must inevitably stand in the eyes of the greatest of American industries—iron and steel. By careful estimate, it was found that one car maker with an output ranking very close to the top, utilized about 10,000 tons per year. Supposing there were 150 companies producing cars who used an equal amount. The total would be 1,500,000 tons, but as there is not anything like that number, the figure will be roughly correct, nevertheless, when we equalize it by considering that Ford, Overland, Buick, Studebaker, etc. make more cars than the firm from which the estimate of 10,000 tons was obtained. Even then we are probably high in the total consumption, but if we are high, the percentage that goes to the automobile industry must be even less than 5 per cent. And 5 per cent is low enough.

To-day it is said that certain of the munitions makers are offering a premimum of 2½ cents and more, per pound, for preferred rollings, this over the present market. Think of that point along with the meager percentage of five, and you will wonder why the automobile industry is treated as well as it is at present.

Some Effects of Conditions

An important result of present material conditions and the future outlook is that designers are paying closer attention to weight reduction and better working out of the details of their cars so that every pound of useless weight can be eliminated. Each pound is important.

There is also chance for capitalization upon the situation. Supposing a maker has bought farsightedly and advantageously. He can raise prices with the present market conditions as an excuse, and thus increase revenue with no added production cost, for the length of his contracts at least. This, it would seem, he has a perfect right to do, and it is a reward for his buying shrewdness.

One thing seems certain. The makers should tell the public plainly how things stand and frankly meet the issue.

Minneapolis Center of Huge and Growing Prosperity

Twin City Show Is Annual Meeting Place for All the Great Northwest—Show Serves 4,000,000 Population

By David Beecroft

MINNEAPOLIS, Feb. 7—The Minneapolis show, drawing its thousands of dealers and tens of thousands of citizens from the great Northwest territory embracing all of the State of Minnesota, all of North Dakota, all of South Dakota and the eastern half of Montana, to which might be added the northern counties in Wisconsin, is perhaps the most potential show west of Chicago. It is a greater gathering point for dealers than Kansas City, Omaha, or Des Moines, and is a veritable magnet for the public throughout the territory, a public which does all of its buying in the Twin Cities and looks to them as New England looks to Boston, as the South looks to New Orleans and as the Rocky Mountain section looks to Denver and Salt Lake City.

Naturally, then, the week's motor car show, with its sixty-four different makes of gasoline cars, its four makes of electrics, its six different makes of motor trucks and its two makes of tractors for the farm, not to mention a small outside tractor show, gives the 4,000,000 from these States the best opportunity to view the show, to shop in the Twin Cities and to meet their friends. Show week is the great gathering together event of the year for the Northwest. Hotels are crowded by reservations booked weeks in advance, theaters play to sold-out houses, lodging houses are at a premium, and the great Northwest measures its strength, takes inventory of itself in show week as it does in no other week of the year.

It is meet that this greatest of all distributing territories for automobiles should have an annual week that measures up with any other city outside New York and Chicago, with the possible exception of Boston, which has more cars on exhibition at its annual show.

These are the greatest years that the Northwest has ever known, and the more conservative bankers of the Twin Cities show you figures which go a long way to establish the fact that it is questionable if there is any other territory on the earth's surface, in this or any other country, where prosperity of all classes has reached so high a mark as in our own Northwest during the past eighteen months.

Prosperity Is Prodigious

The prosperity of the farming communities is staggering. Crops in 1914 were record breakers and sold at high-mark war prices, but 1915 crops were often 50 per cent higher and, while prices have been a little lower, the sum total of crop value for 1915 is vastly in excess of 1914. These two have been years without precedent. The agricultural sections of Minnesota, the Dakotas and Montana have fallen into unexpected wealth, just like the Eastern stock speculator who got in on General Motors or Bethlehem Steel when they sold under a dollar and watched them steadily climb to 500 or higher.

Some farmers who bought "quarter sections," or 160-acre farms five years ago and who for two or three seasons were not able to pay interest or even taxes have within the last two months not only paid off all taxes and interest charges, but entirely paid for the land. This means that all other bills have been paid, and that the proud possessor has a snug bank account.

The condition of a great territory is always reflected in the financial reports of the territory, and the Twin City banks are always a sure criterion of the financial condition of the Northwest. E. W. Decker, president of the Minneapolis Loan & Trust Co., whose estimate of money conditions in the territory stands highest, says there never was a period when the Northwest was in such good financial condition. Scores of the small country banks are carrying deposits of $500,000 with the large Twin City banks, an undreamed of condition. In the four States money is more plentiful than ever before. The interest rate on mortgages in parts of Minnesota has dropped from 6 to 5.5 per cent, and to as low as 5 per cent in a few sections. There has been a more general paying up of old debts of four or five years' standing than ever before; in fact back debts are no more.

When in Rome do as the Romans do, and when in Minneapolis you must think as the Twin City people. Here you think crops, the production of the soil. Money and crops are synonymous. If you sell automobiles, you must think crops, because farmers own over one-half of the 95,000 automobiles in the State of Minnesota. Statistics do not give the farmer percentage in the Dakotas and Montana, but it is equally high if not higher.

Registration 35 Per Cent Up

Perhaps before analyzing what crops were last year, and what they are expected to be this year, we can get a better realization of their value by glimpsing what crops have already done in increasing the number of automobiles in the State of Minnesota. To-day Secretary of State Julius A. Schmall states there are 95,000 cars in the State, while a year ago there were but 68,500 machines. The increase in the past year has been 24,500, an increase of 35 per cent during the year. The secretary estimates that 35,000 cars will be sold in 1916, and he is a good estimator. A year ago he predicted 100,000 cars in the State by Jan. 1, 1916. Unquestionably this total would have been reached had the dealers been able to get all the cars they could have sold. Hence the large Buick distributor claims he could have sold 2000 more cars if he could have obtained them.

Overland, which stands next to Ford in the territory, could have disposed of several thousands more. The same is true in proportion to output with many other concerns of smaller output. There is nobody familiar with the facts who does not believe Secretary Schmall's estimate of 100,000 would have been exceeded could the vehicles have been obtained.

Glance over the growth of motor car, automobile, registrations in Minnesota since 1909, when registration began.

These figures of growth tell best their own story. To them you can add 2000 registered chauffeurs and 474 registered automobile dealers.

1909	7,000	1913	45,800
1910	12,500	1914	68,500
1911	19,000	1915	95,000
1912	28,400	1916 (Estimate)	130,000

Farming Community in 2.25 to 1 Proportion

Looking into the present 95,000 cars owned in the State a further analysis shows that the farming community is a very great buyer. The *Farmer*, in an analysis, shows that 36,000 cars are registered in towns of 1000 population or less. The majority, in fact, nearly all of these cars, go direct to farmers. The relative number of cars owned in small towns and the number in the three large cities of Minneapolis, St. Paul and Duluth, proves the farmer's case still further. These three cities have a combined population of 700,000. The total farm population of the State is 750,000. The total number of cars owned by the farmers is 46,000, whereas these three cities have but 20,000. The farmers are two and one-quarter times as strong in car ownership. In the towns of 1000 population or under the people are buying cars to-day at the rate of one car to every thirty-five people; it is estimated that by 1926 there will be one car for every ten people in the State of Minnesota.

But Minnesota farmers are not anywhere near the saturation point, so far as car buying is concerned. There are 156,000 farmers in the State. The average farm contains 177 acres. The average value of a farm in 1910 was $9,500. Of these 156,000 farmers it is conservative to estimate that 100,000 can afford to buy cars within the next five years. To-day 46,000 of these farmers have cars and 54,000 are waiting to buy.

Perhaps a brief analysis of how certain makes of automobiles have increased in the State during the past year will serve as a better indication of what may be expected this year and next. Ford registrations have increased by 12,000 cars, 2500 of these going to the large cities and 5500 to towns of less than 1000. Overland has increased 2545, 311 going to the large cities, 1522 to the towns of less than 1000. Dodge has registered 948 during the first year of its sales; Maxwell has made an increase of 1291 in the year. Studebaker has increased 2636, Reo 518 and others in like proportions. Here are some of the makes that lead in registrations in the State:

Ford	30,708	Chalmers	826
Overland	7,518	Regal	787
Buick	6,686	Kissel	718
Studebaker	5,637	Packard	653
Maxwell	3,551	Saxon	664
Reo	2,380	Velie	637
Cadillac	1,597	Paige	613
Chevrolet	1,284	Krit	563
Oakland	1,075	Imperial	542
Mitchell	983	Metz	516
Dodge	948	Oldsmobile	505
Hudson	917	Jackson	505
Hupmobile	893	Jeffery	440

These figures show that farmers must be buying cars selling over $1,000, and a straw vote of the Minneapolis distributors exhibiting at the show was conclusive to demonstrate that farmers are gradually mounting in the price scale, and that many farmers own cars listing at more than $1,000.

Minnesota License Lasts Three Years

Minnesota is typical of Middle Western States that do not pay too much for automobile registration. She has a tri-annual system, a registration fee of $3 having been sufficient for three years, or a dollar-a-year rate. The present tri-annual registration dates from Jan. 1, 1915. Beginning with the next tri-annual period, Jan. 1, 1918, the registration fee has already been fixed at $5 for the three years. Registration for the last two of the three years will be $3.50. In Minnesota the license tags belong to the person registering and do not go with the car in case of sale.

During the past year the Twin Cities territory has advanced into a new position in the automobile field by becoming the biggest distributing territory in the country for several makers. Manufacturers are beginning to appreciate the importance of the territory. It is several years since Ford established its large assembly plant here, and preparations are being made practically to double its size.

A step which well indicates the importance of the Twin Cities and the buying capacity of the Northwest is the erection of the mammoth storage building put up last fall by the Willys-Overland Co. and only recently occupied. Here is a huge brick structure four stories high and capable of storing 7500 cars to be held for quick shipment to the hundreds of sub-distributors and dealers in the four or five States served. The new building is a model of its kind, and the only one of its particular type in the country. It is an impressive structure 462 ft. long and 280 ft. wide, occupying one of the most commanding positions on University Avenue, the connecting thoroughfare between Minneapolis and St. Paul. The building is just over the dividing line and stands on St. Paul territory. Although a four-story building, it is much higher from a car-storage viewpoint, as its storage floors are double-decked, the second deck on each floor being a suspended steel frame-work with the long lines of cars carried on two 4 by 6-in. angle pieces. The entire scheme is such that one man can easily push any car off the railroad car from the switch lying along one whole side of the plant to the elevator, and thence to any part of the storage space.

Across the front, on the ground floor, is a mammoth show room, and over it on the second floor are the offices. The basement has a large battery room, and is also used for tuning motors, while half is given over to car storage. On the main floor is a stock room 140 by 60 ft. for spare parts for the territory. Cars are at present being received at the rate of fifty per day, and there is a force of twenty-two men looking after the plant. The salesroom and offices have not yet been opened. The territory served includes Wisconsin, Minnesota, Iowa, Montana and the two Dakotas.

But there have been other automobile activities during the past year. Chevrolet is at present negotiating for a site on which to erect one of its assembly plants; and real estate people are arranging with the Maxwell company for larger arrangements for representation in the Northwest.

Tractor Business Growing Fast

Another motor aspect that has developed in Minneapolis and St. Paul during the past year is the agricultural tractor business. The Twin Cities are to-day the acknowledged home of the agricultural tractor industry, just as Detroit claims similar distinction in the motor car trade, Pittsburgh in the steel industry, Chicago in live stock and New York as the financial center. To-day there are over twenty-five concerns building agricultural tractors, and every week brings a new one to the surface. Nearly every back-yard machine shop has a tractor in development, in fact tractor development is as rampant here to-day as automobile promotions were in Detroit four years ago.

The amazing crops of the last two years have largely been responsible for this development, although the tractor industry in the Twin Cities is over five years old, many having been built eight and nine years ago. The largest producer markets the Bull tractor and will build approximately 5000 next year, while the output of others will range from this figure down to ten machines. There were several makers that put out twenty last year, others that built forty, and others that went over the 1000-mark.

A rapid development of the tractor industry is looked for. The farmer is a heavy car buyer. He has learned the utilitarian value of the gasoline engine. It is not necessary to sell him the engine. It only requires time until he has enough ready cash to replace his horses with the gasoline engine.

The trend of agricultural tractor development will unquestionably follow closely the trend exhibited in passenger cars and also in motor trucks. Already the low-priced machine has arrived in volume. The old price of $3,500 has been cut until you can now buy machines for less than $600. The bottom limit has not yet been reached, but it is certain that the $500 tractor will be the big-column type. This fact is already realized by the tractor makers, and there is more activity in this field than in the low-priced automobile field.

Automobile Dealers Handle Tractors

A point of particular interest to automobile dealers is that tractor makers are turning more than ever before to the automobile dealer as the person to market the tractor. In the past the implement dealer has sold them, but the automobile dealer is accepted as having a better knowledge of the gasoline engine, as having better service facilities and being generally in a better condition to market the low-priced tractor than is the implement man. The automobile dealer sells more than one-half his cars to the farmer, and taking on the tractor line will be quite in harmony with the present movement in the development of his business.

Having noted the very general development of the automobile business in the Northwest during the past year, we must next look to the all-convincing question of crops to get a correct estimate on the buying capacity of Minnesota, the Dakotas and the eastern half of Montana, as well as the northern counties in Wisconsin, the territory served by the Minneapolis distributors.

Minneapolis and Duluth are the two great primary grain markets for this territory. The products of the farm reach these two cities and it is in them that Chicago, Liverpool and the other great grain-buying cities secure their supplies.

Some conception of what grain has been grown in this territory in 1915 can be had from the fact that between Sept. 1 and Jan. 1 there were 264,000,000 bushels of grain shipped from the farms and delivered in Minneapolis and Duluth. In Minneapolis alone, 160,000,000 arrived in these four months. That meant 40,000,000 bushels a month. It meant that every day during those four months a million and one-third bushels of grain were arriving in Minneapolis. It is a staggering total even to blasé grain merchants in this city. But this total does not in any way represent the total volume of grain, because the farmers are holding wheat and oats for higher prices.

Here are a few examples of how the 1915 crop has quite outdone the bumper crop of 1914. The Dec. 30 federal government report gives the value of wheat to the farmer for Minnesota alone at $66,078,000 as compared with $43,834,000 for 1914. Here is an increase in dollars of over $22,000,000, this representing more than a 50-per cent increase in value over 1914.

Now turn to North Dakota: For 1915 the wheat value at the farm was $132,214,000. In 1914 it was $82,408,000. Here is an actual dollar gain of $50,000,000; it is a gain of over 60 per cent in one year.

Turn now to South Dakota: The figures for wheat are $54,835,000 for 1915 as compared with $29,672,000 for 1914. Here the output was nearly doubled in a year.

Lastly, look at Montana and her wheat gain: The figures are $26,384,000 for 1915 as compared with $16,704,000 for 1914. Here is another gain of over 60 per cent in the year.

Wheat Gains $107,000,000

Now recapitulate: Here is $107,000,000 more for wheat alone in these four States than a year ago. These figures are not speculations, they are established facts. But this $107,000,000 means more to-day to the automobile dealer than it would have meant a year ago. To-day the farmer's financial decks are cleared. Last year from his bumper crop he paid his back payments on land, paid back taxes, redeemed his old notes, paid his old implement bills and feathered his bank account. This year he starts without these handicaps of former years. Of this volume of wheat money, which represents but a small percentage of crop value that the farmer has, a good percentage is going toward buying automobiles. No longer is the banker talking against the automobile. To-day he is the greatest booster for it. He now sees it as a utility, an investment. These same bankers today see the time when the agricultural tractor will be considered a sound financial investment to these same farmers. The tractor will enable them to work night and day with relays of men and thus get their crops in in good season. The same program can be followed in harvest time. The tractor will permit of deeper plowing and better cultivation of the soil; in fact, in divers ways the tractor will prove a great improvement over the present horse regime. At present the farmer's horses work 100 days in the year. They are idle 265 days. They must be fed these 265 days. Feeding them costs nearly as much when idle as when working. Herein is one of the great assets to the tractor argument. It is not piling up maintenance costs while idle.

But other crops are well in advance of the 1914 mark. The oat crop value on the farm is $17,000,000 more for 1915 than 1914. The Northwest is the great center of the flaxseed industry of the country. Its value last year was $24,000,000 as compared with $19,000,000 for 1914. Over 99 per cent of this industry is in the Northwest, served by the Twin Cities and Duluth.

Summarizing a few of the crop figures, we discover that for 1915 the total of eight crops aggregates $589,428,000, well over half a billion of dollars. The crops included in this total are wheat, oats, corn, barley, flax, hay, rye and potatoes.

The ratio that the Northwest bears to the entire country is obtained from the figures for the country on these same crops for 1915, where the grand total is $4,662,926,000, as compared with $3,235,319,000 for 1914. This represents a net gain of over $425,000,000.

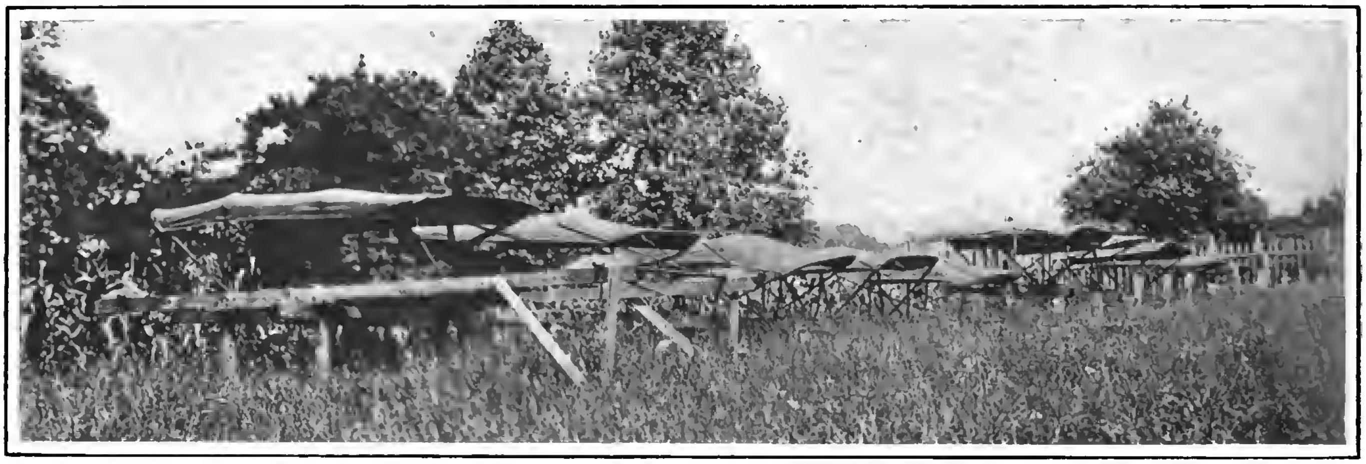
Physically the Northwest territory is as stupendous as the value of its products. It is a giant in dimensions. From Minneapolis to the limit of the territory in Montana is a 20 to 24-hr. ride on the limited trains. In area the States of Minnesota, North Dakota, South Dakota and one-half of Montana, to which is added a fringe along northern Wisconsin, exceeds the area of France or Germany. You could set six New England States in this area.

So great is this area—to be exact, 306,134 square miles—that you could put the whole 100,000,000 population of the country in it and there would only be 329 persons to each square mile. The population would not be nearly so dense as the present population of the State of Massachusetts, which has 418 persons to the square mile. It would scarcely equal New Jersey with 337 persons to the square mile. It would fall far short of Rhode Island with its 508 persons to the square mile.

Thus do we get some slight conception of this enormous Northwest with its empire dimensions and its city population of but 4,000,000. Its fertile fields can accommodate twenty-five times this number and then not suffer from congestion. Why should not our automobile makers with an eye looking to the future seize upon this great logical center for distribution and perhaps assembly? Are our tractor manufacturers to be criticized for selecting such a center for their industry which by 1955 will be a giant?

Use of Magnetic Materials

Circular No. 17 of the United States Bureau of Standards, on "Magnetic Testing," is published for the benefit of engineers and others who are interested in the testing and use of magnetic materials. It gives definitions of the fundamental magnetic quantities ordinarily employed in technical work, outlines the scope, and describes the methods of magnetic measurements employed at the Bureau of Standards, and discusses the type of data required in engineering work.



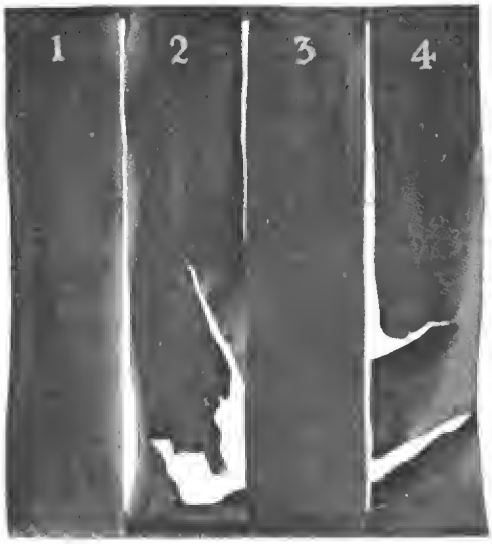
Tops of various manufacture tested by the Du Pont company for a year in an open field. They were opened and closed more frequently than if they had been mounted on cars in active service. Water was allowed to collect and stand on the tops for weeks and months at a time, as illustrated at the bottom of page 271

Solving the Upholstery Problem

Fabrikoid, a Du Pont Product, Developed To Supplant Split Leather on Popular-Priced Cars—Durability Demonstrated by Tests—Rayntite Is a Similar Material for Tops

IT has often been remarked that whenever the natural supply of an indispensable commodity decreases, or the demand for it increases, to a degree which threatens to embarrass the industries affected, the ingenuity of man rises to meet the emergency.

The uses to which leather is customarily put have increased enormously in recent years, and no more striking illustration of the multiplication of demand is being presented than the rapid growth of the quantities required for upholstering automobiles. Added to this and the widening of the other fields in which leather is largely used comes the great demand from abroad due to the European war. Then, too, the supply is not increasing in proportion to the heightened demand, while prices resultant upon these conditions make it very difficult, if not impossible, for the manufacturer of the popular-priced cars to use the best quality leather, usually referred to as No. 1 machine-buffed leather, which is conceded to be the best possible material for this purpose.



Results of an eight-hour test of the relative surface durability of Fabrikoid and split leather made on the machine illustrated at the top of page 271. No. 1 is black Fabrikoid and No. 4 is black split leather. No. 2 is Spanish-finish split leather and No. 3 is Fabrikoid in the same finish

To meet the demand thus created the Du Pont Fabrikoid Co., Wilmington, Del., after two years' work, developed, about 1912, a grade of its product, Fabrikoid, suitable for upholstering automobiles. This material, the company claims, is superior in finish and durability to the so-called "splits," or sublayers of leather usually employed for automobile upholstery in default of the No. 1 machine-buffed grade, while it compares favorably in price with any of them. Moreover, the Du Pont company regards its type of upholstery material as the logical solution of the upholstery problem, the difficulty of which is enhanced by the low car prices due to keen competition. Another feature of the situation is the great increase in the demand for leather in manufacturing articles for which the Fabrikoid type of material is unsuitable.

Minimum Waste in Cutting

The Du Pont company estimates that 75 per cent of the cars on the American market for 1916 use upholstery of this type, of which 60 per cent will be Fabrikoid, stating that this is one of the improvements in efficiency and economy which made possible the low prices characterizing the majority, as compared with previous years. Over 70 per cent of the 1915 cars were fitted with this type of upholstery, of which 40 per cent was Fabrikoid, according to the same authority. A prominent factor in the economy attending its use is said to be the small percentage of waste in cutting, as compared with leather. Since Fabrikoid of the grade used for automobile upholstery is shipped from the factory on rollers carrying rolls of material 60 yd. long and 50 in. wide, the waste is minimized in handling, whereas the irregular shape of a hide renders it practically impossible to avoid a waste in cutting of 25 to 33 1/3 per cent.

Grain Is Embossed

Fabrikoid is made of moleskin, a very fine, closely-woven grade of cotton cloth, over which is spread under pressure, a coating of soluble cotton mixed with mineral coloring pigment and other ingredients imparting the qualities of pliability, toughness and elasticity. The first coats are very thin to insure anchoring the jelly to the cloth filaments. The resulting product goes to the embossing machine where it is given the desired grain by electroplates of real grain leather. The more popular grains are embossed by the use of rollers, this method facilitating quantity production, while the other varieties, which are made in smaller lots, are taken from plates being easily changed and less expensive than the rollers. Castor oil is one of the ingredients used in the jelly coating, the latter being practically the same as that used for coating the split leather used for upholstery work. The quality of the goods is determined by the number of ounces of coating solution applied per square inch, while the grade of cloth used depends on the tensile strength required. Prior to the development of the wide demand for materials of the Fabrikoid type, it was impossible to obtain the cloth used in their manufacture from American weavers, but more recently looms of the type required for its making have been constructed so that there is now no difficulty in securing it.

Strength and Thickness Uniform

Besides the qualities of pliability, toughness and elasticity mentioned, Fabrikoid is waterproof, easily washed with soap and water, not affected by extremes of temperature and oil or gasoline cannot stain it. Another advantage, as compared with split leather, is pointed out by its manufacturers to be its uniform strength and thickness throughout.

Tensile Strength 350 Lb. per Square Inch

Motor Quality Fabrikoid, as the grade for automobile upholstery is called, is made in plain black grain, the Du Pont company stating that its tensile strength is indicated by the fact that it has withstood a tensile strength test of 350 to 400 lb. per square inch, whereas a piece of split leather broke at 157 lb. The method of making this test and its results are shown in the accompanying illustrations. A folded strip of Fabrikoid and a similar strip of split leather were secured to the two scale beams illustrated, and to the lower end of each was attached a pail of sand. The Fabrikoid remained intact at 350 lb. pull, while the split leather broke at 157 lb.

An Abrasion Test

Another test made on the same machine to determine the relative strength and durability of Fabrikoid and split leather consisted in a continuous whipping of parallel strips of these materials held by the horizontal frame as illustrated, the whipping means being beaters like sewing machine belting attached to the revolving rack driven by belt from the electric motor. The ability of Fabrikoid to withstand severe surface abrasion was clearly demonstrated, the only effect after eight hours' whipping being a slight stretch, whereas the similar strip of split leather stretched badly and broke after three and a half hours.

During the year that the top materials were under test at the Du Pont plant the frames were frequently loosened and water allowed to collect and stand for weeks and months at a time to test their waterproof qualities

Machine for testing tensile strength and surface durability of leather, etc. A strip of Fabrikoid suspends the pail at the left, which contains 350 lbs. of sand. The strip of split leather suspending the pail at the right broke at 157 lb. pull. The beaters, attached to the rack revolved by belt from the electric motor, play on parallel horizontal strips of Fabrikoid and split leather. The results of this test are illustrated on page 270

The manufacturers state that Motor Quality Fabrikoid has been used for two years by several of the largest producers of automobiles in the country on several hundred thousand cars. During that period, they say, there has been only one complaint, a defective piece of goods being found on the driver's seat of a single car.

Rayntite—a Top Material

Closely associated with Fabrikoid is the material made by the Du Pont company for automobile tops. This is called Rayntite and it is manufactured in both single and double textures. Single-texture Rayntite is a Fabrikoid, and is waterproof, sharing the other properties of that material as well. The double-texture material is Fabrikoid combined with a cloth backing. Before Rayntite was put on the market it was tested for a year in competition with top materials of other manufacture, the tops being mounted side by side in an open field, as shown in the accompanying illustration, where they were exposed to all sorts of weather. They were also opened and shut frequently, in fact more than would be the case if they had been mounted on cars during the year of the test. The other illustration shows how the tops were left loose on the frames so that water might accumulate on them and test their waterproof qualities when subjected to this condition for weeks and months at a time.

The Du Pont company's business for 1915 was almost double that of 1914, due chiefly to the increase in sales of Fabrikoid and Rayntite materials to automobile manufacturers. A corresponding increase is expected for 1916, owing to the quality of the results shown on cars equipped with these materials and the increased output of popular-priced cars.

Winton Sixes on Standardized Chassis

Motors of Similar Design for Large and Small Chassis of 138 and 128-In. Wheelbase—Unit Power Plant Construction

WINTON policy for 1916 is summed up in two chassis with two six-cylinder motors and two lengths of wheelbase, as announced early in December, 1915. With the option of motor and wheelbase as the primary matter of choice, there are a number of secondary options such as the color scheme, wood or wire wheels and body design. Another interesting feature is that the chassis can be secured with two different types of bodies for winter and summer use and no mechanical changes are required in mounting the different bodies. All the wiring is brought to a single connection on the dash so that no electrical complications are met with in making the change.

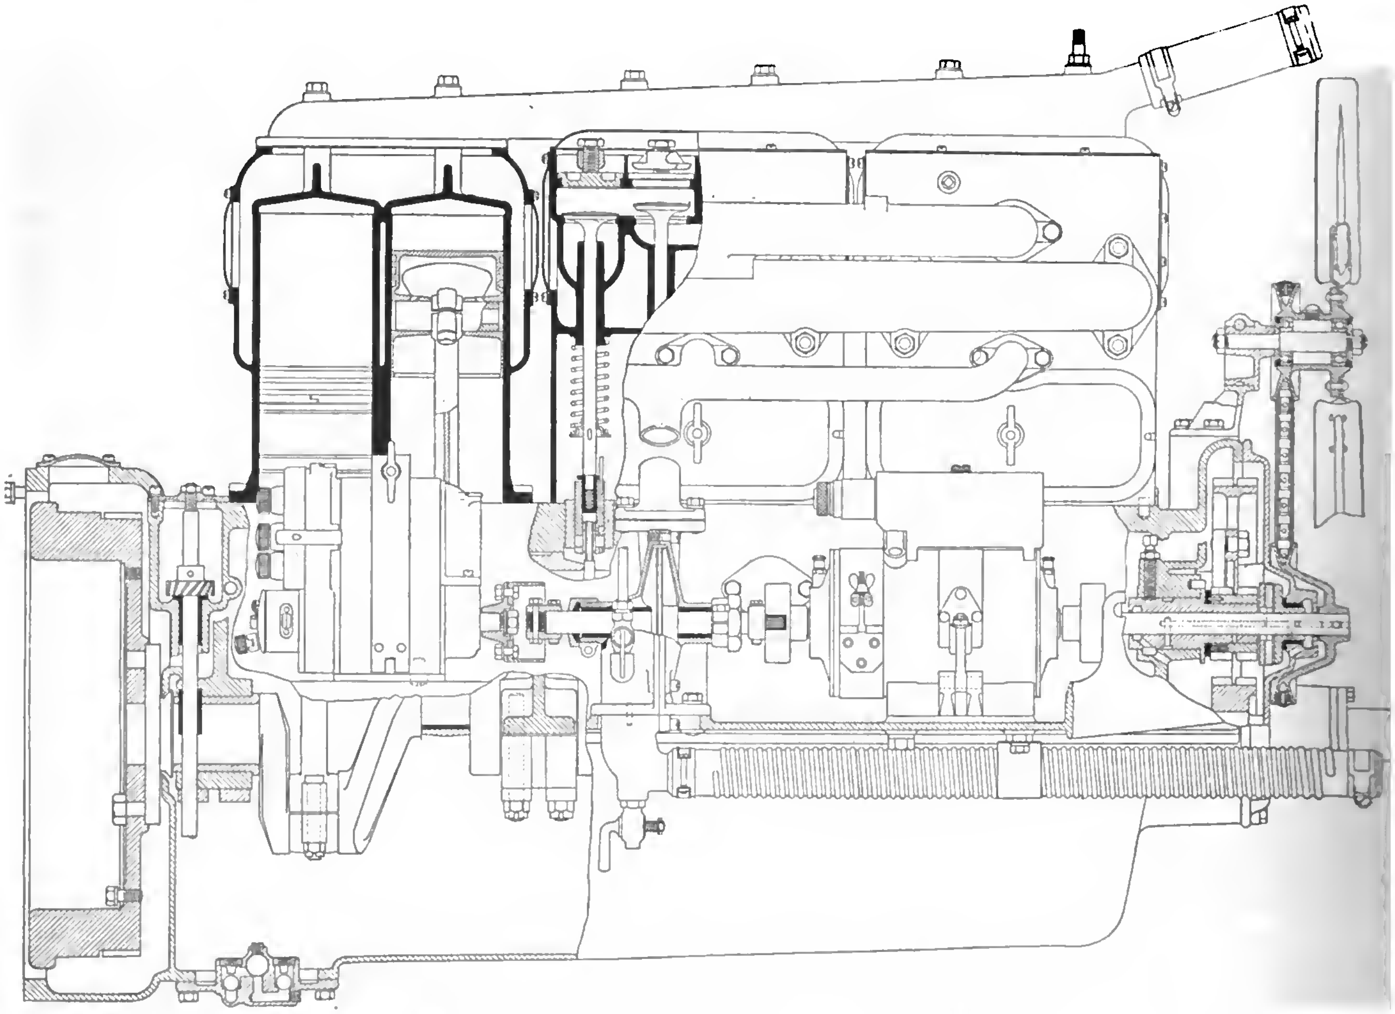
The Winton models for 1916 are known as the 33 and 48, the prices for the stock cars being respectively $2,285 and $3,500. Both cars are built to give the highest degree of comfort and luxury combined with low upkeep cost. Mounted on wheelbases of 138 and 128 in. the cars are fitted with roomy seats, deep upholstery and the latest features of mechanical equipment. The design follows up-to-date practice with left drive, center control, unit power plant, underslung rear springs, vacuum feed, magneto ignition and a motor-driven tire pump is incorporated within the stock jobs.

Both motors are similar in design, the 48 has its six cylinders cast in pairs and with dimensions of 4½ by 5½ in., has an S. A. E. rating of 48.6 hp. Following the tendency of the times all the moving parts of this motor are fully inclosed and all possible parts operate directly in an oil bath. The cylinders are cast of close-grain iron ground to a mirror finish and submitted before assembly to a hydraulic test of 300-lb. per square inch, the waterjacket space surrounding each individual cylinder.

The piston rings are concentric and in carrying out the balance scheme all the pistons, rings, connecting rods and wristpins must be of the same weight per set. Hardened tool steel is used in the piston pin, and as will be noted in the accompanying sections the connecting rods are long to reduce angularity of operation.

Chain Camshaft Drive

Following through the valve action it will be noted that the camshaft drive is by silent chain from the crankshaft. The camshaft and cams are a one-piece integral forging

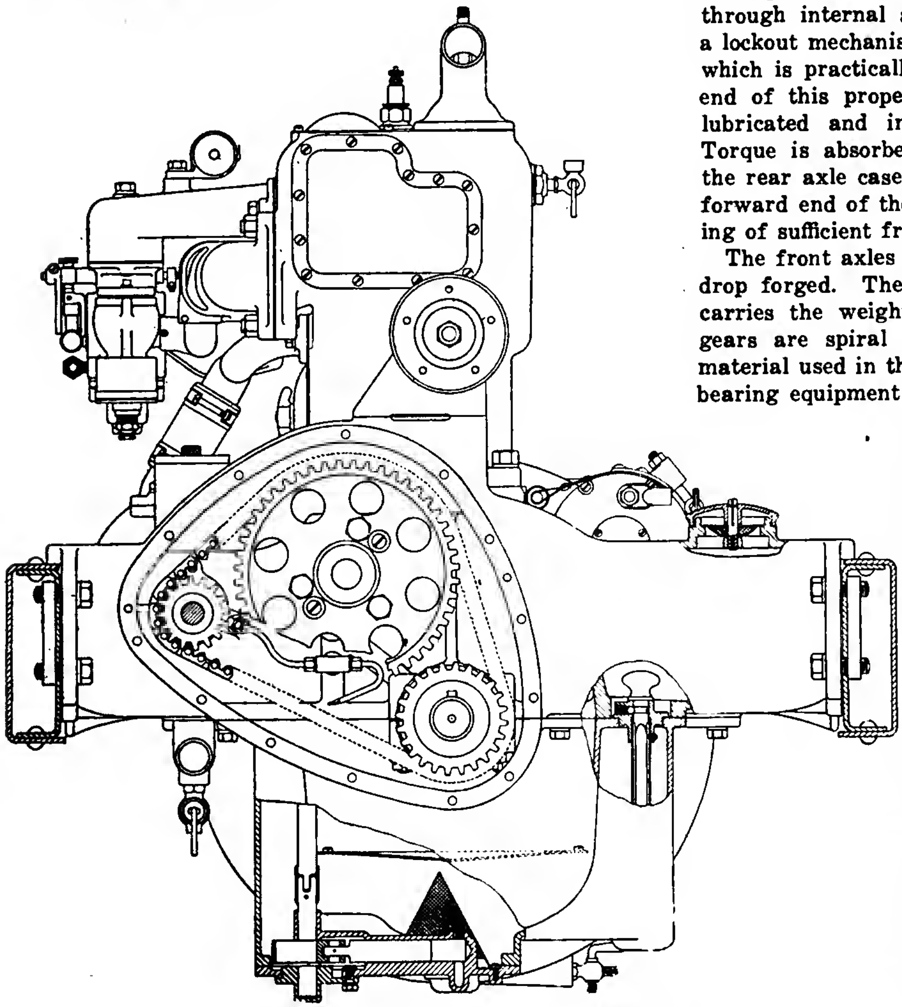


Partial section through Winton six-cylinder motor showing details of cylinders, pistons and valve acti with the profile of the cams such as to provide a gas flow proportional to the piston speed, and the entire shaft can be removed through the front of the timing case without removing the valves, valve springs, pushrods or rollers. To increase the durability of the chain the latter is equipped with a Moore eccentric takeup attachment. All the valves are the same size and the exhaust valves are of tungsten steel with nickel steel valve heads for the intake side. Covering the valve springs, plungers and adjustment points are steel plates.

Materials Chosen Carefully

Throughout the entire car the materials have been made the subject of a careful study. The crankshaft is chrome nickel steel having a tensile strength of 130,000 lb. per sq. in. and runs on four bearings bushed with Parsons' white brass, the crankshaft bearing surfaces being ground to a finish fit. For the crankcase, aluminum is used and the casting is provided with integral arms resting on the main frame. Also integral with the crankcase is the base pan extending from arm to arm, and the case itself is divided into two halves with the bearings all supported in bridges in the upper half. Fitted to the crankcase are a drain at the bottom for flushing and a breather pipe.

Electrically the car is equipped with the Bijur two-unit starting and lighting system and Bosch ignition system with storage battery to supply auxiliary current for starting. The magneto is strapped to the motor base and is connected to the water pump shaft by an adjustable metal coupling. A feature of the layout of the motor is the neatness of the wiring. It is all inclosed in insulating tubes and removable at the spark plugs without tools by means of quick-detachable clips.



Front view of motor with timing cover plate removed

Carburetion is by a Rayfield, which is of a special design to meet the needs of the Winton motor. In order to facilitate gasification of the fuel it is both hot waterjacketed and equipped for hot-air supply. To take care of the changes in adjustment of mixture due to different temperature conditions there is a gasoline primer operated from the cowl board and also a dash air control.

Lubrication is by pressure feed, the oil being circulated by a plunger pump located in the lower half of the crankcase. This pump is driven by spiral gears from the camshaft and takes the oil through a screen from the reservoir and delivers it through a tube cast in the crankcase to the main bearing. From these points the oil enters conduits drilled in the crankshaft through which it passes to the lower connecting rod bearings and also by means of a tube to the front chain and sprockets. The cylinders, camshaft bearings and cams are fed by the oil which is thrown from the connecting rods, and in order to distribute the oil completely around the periphery of the cylinders oil grooves are cut around the pistons. Other parts of the car such as the steering connections and spring bolts are provided with grease cups while the springs are taken care of by Dann lubrication cushion inserts.

Smaller Motor Almost Identical

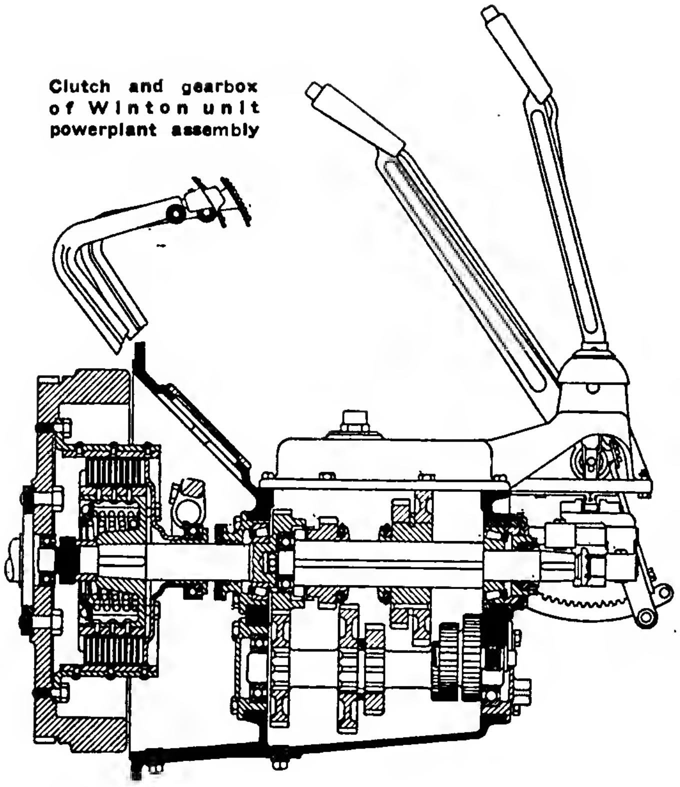
The description of the 48 motor fits the 33 except that the dimensions of the latter are 3¾ by 5¼ and the S. A. E. rating is 33.75 hp. The equipment and general detail of design is the same in both instances. Throughout the remaining chassis specifications a marked similarity also exists. Both cars have dry plate clutches with seventeen disks in the 48 and eleven disks in the 33. Both cars have four-speed gear boxes with direct drive on third speed through internal and external gear combination. There is a lockout mechanism on reverse and final drive is by a shaft which is practically horizontal under normal load. At each end of this propeller shaft is a universal joint internally lubricated and inclosed in a grease-proof metallic case. Torque is absorbed through a torsion rod extending from the rear axle case to a cross member of the frame. At the forward end of the rod there is a link with ball joint allowing of sufficient freedom of motion to give a flexible drive.

The front axles are Elliott type, I-beam section, integrally drop forged. The rear axle is floating, the housing which carries the weight being of pressed steel. The rear axle gears are spiral bevel with bevel gear differential. The material used in the gears and pinions is nickel steel and the bearing equipment is Timken roller throughout.

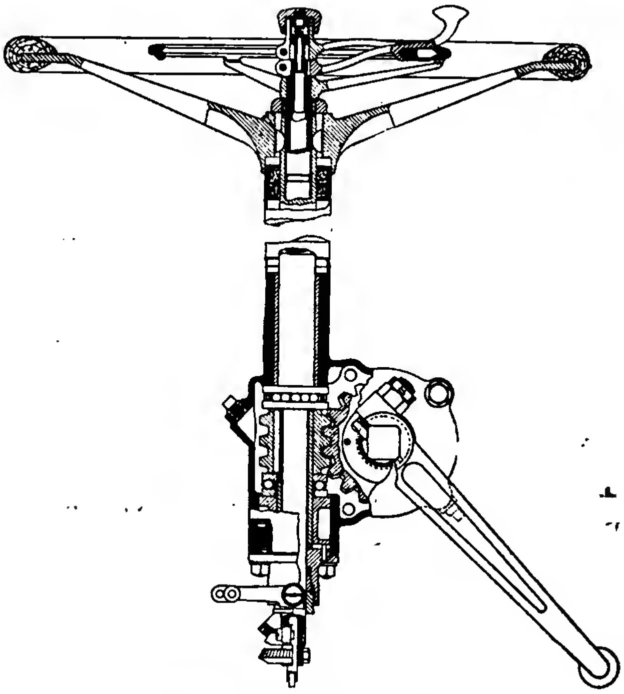
Some of the other important chassis specifications include 37 by 5 tires on the 48 and 36 by 4½ on the 33. Non-skid rears are furnished and the standard equipment is Firestone demountable rims. On the cowl board the equipment includes a combined lighting and ignition switch with Yale lock, ammeter, carbureter control, speedometer clock and gas primer. The instrument board is lighted by electric lamp. The windshield is a ventilating rain-vision design carried over the cowl board, and the cowl itself is of cast aluminum. Floor mat, foot rest and collapsible robe rail are included in the tonneau, and divided front seats are optional.

The Winton company pay particular attention to the finish of their cars and will supply bodies furnished in any color, and will also make special prices for sets of one chassis with two interchangeable bodies.

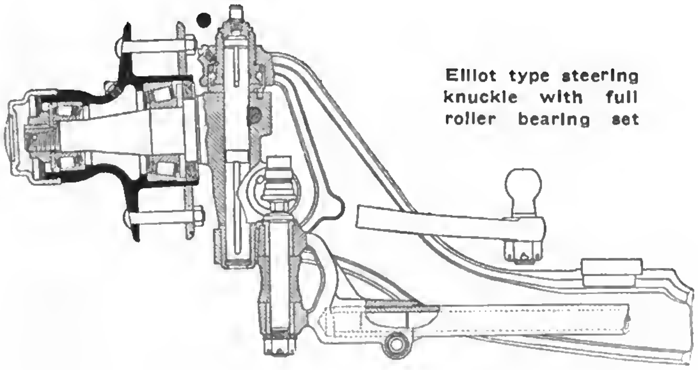
Details of Winton Sixes



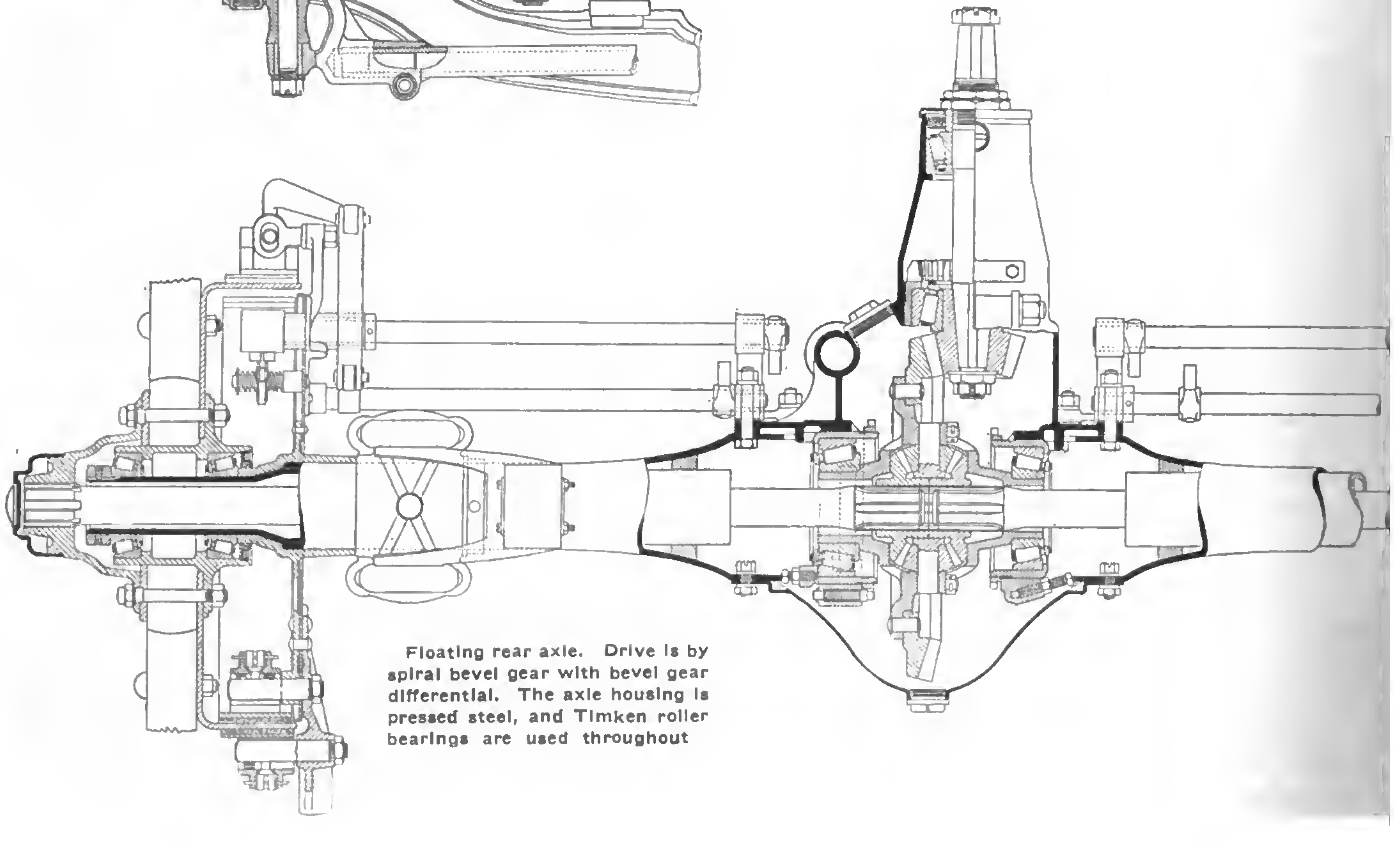
Clutch and gearbox of Winton unit powerplant assembly



Steering column and control—Column held rigid by support attached to cowl board with worm and gear steering mechanism supported by long bearing surfaces. The steering mechanism is equipped with ball thrust bearings and the steering side rod has a ball joint at each end provided with springs to give flexibility and take road shock. Steering links adjustable



Elliot type steering knuckle with full roller bearing set



Floating rear axle. Drive is by spiral bevel gear with bevel gear differential. The axle housing is pressed steel, and Timken roller bearings are used throughout

The History of the American Automobile Industry—16

Hot Air Engine Subject of Many Experiments—Hydrogen and Other Gas Engines Before 1800—Electric Ignition Used in 1807—Regenerative Air Engine

By David Beecroft

IN 1796 Lebon d'Humbersin of Paris received French patent No. 37 for a method of distilling gas from wood, closely following experiments in England by Murdock and others who distilled gas from coal. In 1801 he patented an air engine having three double-acting cylinders. Two of these were used respectively for air and gas which passed through a mixing chamber into a combustion chamber, where they burned and expanded and were then carried to the working cylinder. This device is therefore a very close anticipation of the Brayton engine of seventy-five years later, and, while right in general theory, undoubtedly gave much trouble because of the difficulty of handling and the losses involved in attempting to carry the red-hot gases from the combustion chamber through valves and pipes to the working cylinder. Lebon was assassinated soon after devising this motor and the work ceased.

Cayley's Engine on Practical Lines

He was closely followed, however, by Sir George Cayley, who, in 1807, brought out his hot-air engine and presented it to the public instead of patenting it. His device is particularly worthy of attention because it has finally led through many steps of improvement to the modern internal combustion engine that is driving the great majority of modern automobiles. He patented in 1837 the application of this engine to an automobile, which shows a well worked out device having two or more cylinders, water cooling and self starting so long as the fire was burning. The Cayley device is simplicity itself in conception, but offered a goodly number of difficulties in the attempt to carry it out, particularly in attempting to secure high economy, low first cost, long life and similar important features.

This engine pumped atmospheric air into the ash box of a tight furnace, which air passing through the flame or burning fuel was intensely heated, mingled with the combustion gases and, greatly expanded, was then sent to the working cylinder which it operated, just as steam operated the steam engine, after which it was exhausted. The pressure was, of course, limited to that which might be readily secured by the compression pump. The amount of heating could be much or little, as desired, by passing part of the air around the fire, but whether much or little it was still very high for the inferior lubrication, poor workmanship and inferior materials of those days. Speeds were low and the grit from the fuel undoubtedly quickly destroyed the valves and piston rings. That very little came of this device at this time is not surprising under these circumstances. It would show really practical results to-day.

Use of Electric Ignition

Some modification of it would seem to be particularly advantageous for converting the heat energy of peat into mechanical power, because a wet fuel would tend to develop much steam with consequent high internal pressure and low internal heat, and thus avoid the destruction of the metallic parts and the necessity for great exterior cooling found in most of the hot air engines.

So far the electric spark, although known, seems not to have been used for gas engine ignition, although suggested for firing guns by Benjamin Franklin in 1751 and by Joseph Priestley in 1761, and for air engines by Lebon in 1801. It is claimed that in 1807 de Rivaz actually constructed an engine employing hydrogen and air fired by an electric spark. He is said to have used a cylinder of about 4¾ in. diameter and to have applied his engine to a small locomotive. It is quite probable that this was also of the open-cylinder, free-piston type. The hot-air engines having continuous fires did not need electric ignition, and liquid or gas fuels were not common.

The Stirling Engine

In 1816 Rev. W. Stirling, Scotland, invented a hot-air engine, afterward patented in 1827 and 1840, which used the same air over and over and employed a displacer piston instead of a pump piston, in addition to the working piston. The displacer cylinder was cooled and the working cylinder kept hot by a fire, and the total volume of contained air would be expanded or contracted according to whether it was thrown by the pistons into the hot cylinder or into the cool one. The working piston would be pushed outward by the expanded air and sucked inward by the contracting air. No valves were necessary and the displacer piston was very light, being hollow, and was usually carried by its piston rod so that it required no oil and caused little or no friction. This form of engine found considerable favor and grew in popularity until the end of the century, when it began to be displaced by the smaller, lighter and cheaper now common gas engine.

Even more important than the engine was the "regenerator" or "economizer," which he employed between the hot and cool cylinders to absorb the heat of the air as it passed toward the cool one and to again give it out as the air passed toward the hot cylinder, which arrangement added much to the economy of the device. This regenerator has found extensive use in many industries where high heat is needed and many metallurgical processes would not be profitable and often not possible without it.

Some Leakage of Air

While the above description applies to the Stirling engine as usually made, it was found that there were some losses of air by leakage, and that unless this leakage was made up in some manner the air became so rarified that it had little heat-absorbing capacity, and the engine lost power. On this account it was common not to attempt to get power from the vacuum, but to provide a check valve opening inward which would admit atmospheric air and so maintain the working medium.

A 50-hp. Stirling was used for some years at a Dundee foundry in which the air was maintained under about 200 lbs. compression by a pump, showing even at that date recognition of the fact that this compression permitted more power from a given size engine. Its bore was 16 in. and stroke 48 in. Several reports are extant of the efficiency of this device, the lowest one being 8.5 per cent, which is probably closely correct. It was abandoned after a few years because of failure of the heating surfaces. Modern materials and methods of treating them would have prolonged its life many times.

In 1820, before the Cambridge, England, Philosophical Society, Rev. W. Cecil described an engine using hydrogen gas and air to produce an explosion followed by a vacuum. His engine ran with perfect regularity 60 r.p.m., using 17.6 cu. ft. of hydrogen per hour. He explained that his engine could be used either direct acting or on the gravity system. By the former we understand the now common practice of using the pressure of the expanded charge, and by the gravity system we understand that which was common in those early days and after adopted by Otto & Langen in their free-piston engine, which is well known to most present-day gas engineers. In those days of low pressures there was considerable question as to which method was the better. Although it was not until about 1862 that Alph. Beau de Rochas explained to the world with perfect clearness the cycle of operations now widely used, Sadi Carnot had correctly stated the important heat laws about 1826 and it seems to have been fully understood even in those days that a rapid expansion of the gases was necessary in order to get good power and high economy. In fact, any observer could hardly avoid noticing the cooling effect and loss of power so plainly evident in the first explosions of a cold, slow-moving engine. Rochas' requirements were stated as (1) the greatest possible cylinder volume with the least cooling surface; (2) the greatest possible rapidity of explosion; (3) the greatest possible pressure at the beginning of expansion; and (4) the greatest possible expansion. It is not likely that these earlier experimenters grasped the problem so fully as did Rochas, but it seems certain that they were hindered more by the mechanical difficulties than by a lack of knowledge just as Rochas himself did not carry out his own theories, but left them to be embodied by Otto 14 years later.

Rev. Cecil also describes some earlier experiments by Professor Farish, who exhibited in his lectures an engine working by the explosion of air and gas. It is also said that Farish had operated an engine by gunpowder. These engines of Cecil and Farish seemed to be the first well-authenticated, actually working devices of the internal combustion kind. Their exact construction is not clear, but Cecil seems to have used two pistons in connection with a single combustion chamber.

Great Activity After 1820

With the rapidly improving roads, a rapidly extending commerce, and a greatly increased use of the steam engine as a source of power, it was but natural that the period beginning about 1820 should be marked by great activity in the motor vehicle line in England. Naturally this activity was known in other lands and partly responsible for some of the efforts put forth both in France and America. Undoubtedly the growing use of the steam engine even with its many imperfections stimulated at first, at least, attempts to propel vehicles with other sources of power, among which were hot air, already mentioned, rarified air and compressed air. While the advantage of compressed air for doing work at a distance was not unknown, it seems that very little use thereof had been made in these earlier experiments. British patents issued to George Medhurst in 1799 and 1800 describe "A condensing wind engine for all of the purposes in which steam, water, wind or horses are employed." Also "A new improved method of driving carriages of all kinds without the use of horses by an improved Eolian engine, which may be applied to various other useful purposes." Medhurst further describes that this air may be stored by manual power, by water power, by wind power or by explosive or effervescent substances. He also describes various work that may be performed by his devices and mentions charging stations as well as portable reservoirs or magazines.

Small carriages were to be driven by rotary engines, the larger to have reciprocating engines with speed changing gear. He also describes a gunpowder engine in connection with an artillery wagon. Medhurst designed a pneumatic tube system and published several pamphlets that the knowledge of his inventions might be disseminated.

The FORVM

OLD DURYEA CAR STEERED EASILY—OBJECT OF HEAVY CONSTRUCTION FOR TRACTORS—THICK BRAKE DRUM REDUCES HEATING

Improving the Steering

By A. Ludlow Clayden

IN reply to Mr. Duryea, I must confess that his method of describing the action of bicycle steering is better than mine was. We both meant precisely the same thing, but Mr. Duryea has chosen a better method of expression. However, as to the tilted pivot being the same thing as a pivot placed centrally in the wheel, I must retain my former opinion that it is not and never can be the same. Of course the turning moment of a blow struck on the wheel by an obstacle in the road is lessened by tilting the pivot, and if the pivot angularity is increased, so will the turning moment be reduced, but it cannot be brought down to nothing.

Certainly the old Duryea cars which I enjoyed driving ten years ago or more, did steer well, but the details of their steering were good and the pressures on the various parts were light. Also, and this I think is important, the long tiller for steering, without reduction gearing, gave one the ability to "feel" the steering. Driving a Duryea on a good road was more like steering a boat in smooth water than controlling an ordinary automobile. On rough roads it was always my experience that one was wise to keep a good grip of the tiller, but that may have been because road shocks are so often of a slightly glancing nature with a distinct horizontal component.

Future for Light-Weight Tractor

By Marius C. Krarup

In reading the extracts from Mr. Eason's paper on the development of tractors and their manufacture, I notice a number of reasons for the inclination of manufacturers to stick to the traditional heavy and crude construction with cheap materials, but I find no mention of the most importan factor which makes them so conservative. This is the need of great weight over the tractor wheels to make them pull and overcome great resistance.

Cleats, or adjustable traction blades projecting more or less from the wheel rims are indispensable on soft ground even when the tractor is heavy and can only to a very limited extent take the part of weight for securing the necessary tractive effort. They are troublesome on the road and on hard fallow ground; they cause vibration which is injurious to a light-weight power plant and mechanism designed on the automobile plan, and they militate against the speed which should contibute to making the motor tractor pay for itself. In other words, the tractor system dispensing with heavy-weight construction has not yet been satisfactorily developed. The best that can be done with a light-weight tractor at present is to load it down when it is to do heavy work—likewise as a man jumps upon the back of a light mule to make it pull as much as a horse—or else to use the caterpillar tractor system, which, however, is not adapted for small and inexpensive farm machines.

Rational efforts for introducing light-weight automobile construction for farm work must therefore be aimed first of all at revolutionizing the propulsive system. To make the work done in the soil push or pull the power plant ahead, or to make it help in doing so, is the most radical thought in this connection. The Lanz machines and the von Meyenburg machines are the best examples of this principle. The soil is milled by tools rotating in the same sense as tractor wheels, and the resistance of the soil against the movement of the tools therefore assists in propulsion. But the work done is not plowing or harrowing. (The rotary disk harrow operates the other way, and does only light work, comparatively.) It is soil-tilling on a new plan, to which farmers must first become reconciled. The work done per acre consumes, so far, from 1.7 to 2 times as much motor fuel as plain plowing, but separate harrowing can in many cases be spared, as the new tools divide the soil much more finely than the plough does. The returns in the form of increased crops or final economy in cultivation are not yet proved.

One of the strongest mechanical objections to soil-milling, with the methods and soil tools which have so far been tried in public, is the necessity for rotating the tools very rapidly—approximately four times as fast at the prongs of the tools as the linear forward speed of the machine as a whole—the result of which is that these tools are easily broken or injured when striking stones in the soil. Another objection is that when the soil resistance is great the milling is slighted and the propulsion is favored.

Brake Drum Thickness Affects Heating

By E. H. Delling

Chief Engineer Mercer Automobile Co.

I have read Mr. Booth's article, "Working Out of the Rolls-Royce Brake," with interest, and find that our experience in the designing of a brake has been very similar to his.

We have had trouble with accumulating a great deal of heat in the brake drum of the propellor shaft brake, due to the fact that the shoes with asbestos lining are insulated and cannot therefore conduct the heat away. We are using a high carbon steel casting for our brake drum at present, incorporating cooling ribs on the outside.

We found we still could bring the brake drum to a black heat when abusing the brake violently in succession. We increased the thickness of the wall of the brake drum only 1/32-in., and this slight change made a wonderful difference. We can only bring these brakes to a dark yellow at present, which we think is not a dangerous heat in a brake of this type. We might add that our brake shoes are made of aluminum.

Tipton Uses Balanced Rotating Sleeve

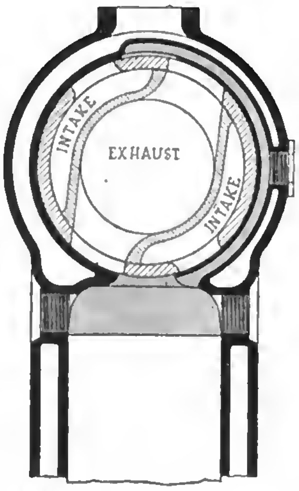
Cored Passage for Inlet and Central Bore for Exhaust in Overhead Construction—Unique Connecting Rod, Flywheel and Crankshaft Assemblies

A UNIQUE form of sleeve valve motor has recently been designed by W. P. Tipton. It is intended to overcome inertia in the valve gear in high-speed motors by employing a rotary action.

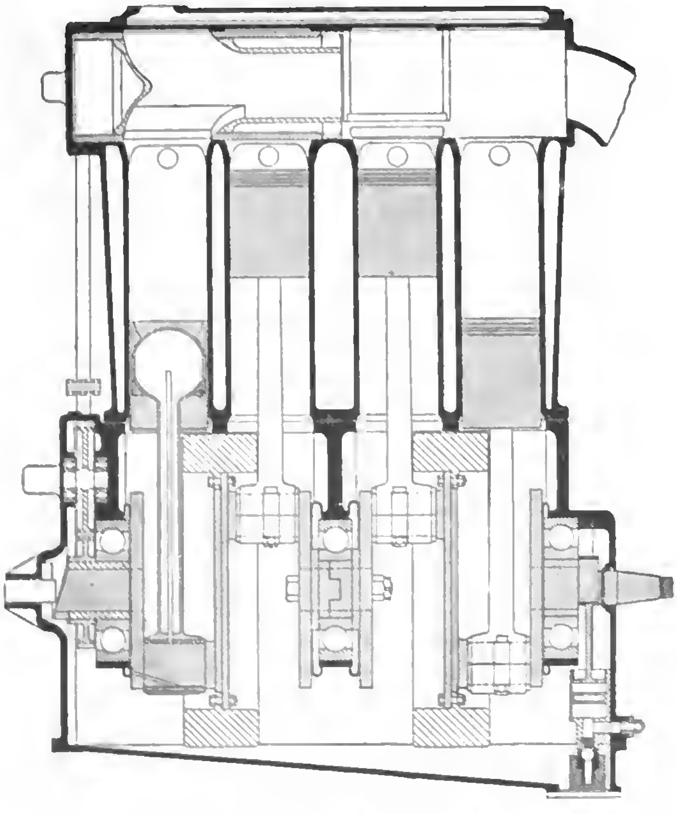
The valve design is distinctive in that it has two concentric chambers, the inner for exhaust and the outer for inlet gases. On a 3½ by 6¾-in. motor the valve diameter will be 5 in. and the area of the valve ports will be 4.844 sq. in. or 50 per cent of the piston area, a ratio which is suggestive of good action at high speeds where the greatest possible volumetric efficiency and the most reasonable gas speeds are desired.

The inlet gases are led to the combustion chamber by way of the annular bridged slot shown in the middle of the valve, which slot is connected to the carbureter through the inlet manifold. This construction is clearly shown in the longitudinal and transverse valve sections in the accompanying illustrations.

Accurate balance of the valve is secured by a second, diametrically disposed port of equal area, which distributes the gaseous pressure on either side of the valve. The passage for the gases to this balancing port is through a duct cored around the valve in the cylinder casting.



Section of Tipton Valve



Tipton motor, showing spherical connecting rod end

The area of the valve surface passing the ports during the compression and expansion strokes is inclosed by four interlocking bars of cost iron lying in grooves in the valve shell and held against the valve walls by a flat steel spring in back of the bars. With a reasonable amount of lubrication it is intended that this design should assure a gas-tight fit, without reducing the clearance between the valve and the wall.

Provision is made against warping by using an outer shell of 5/16-in. steel tubing into which grooves for compession rings are cut, also the teeth at the forward end of the valve for guiding purposes. The exhaust passage is of cast iron and is lightly welded at all contact points to the outer shell. As the outer shell is partially cooled by inlet gases as well as by the water-jacketed walls, and as it is heated and cooled uniformly throughout its entire area and not locally, the designer states that uniform expansion should occur and the vastly greater strength of the outer shell will overcome the warping stresses set up in the cast-iron exhaust passages.

The bearing speed of the valve is low in comparison to that of the piston, the ratio being 428 to 1000; and, as its load is small lubrication should be simple. The designer takes care of this by a small force feed introduced at five points, one between each pair of cylinders.

Another interesting part of the design is the ball-end connecting rod. This rod is tubular, having a flare at the upper end and a hemispherical pressed steel shell welded on. The entire end is ground spherical and an adjustable aluminum alloy guide is made with compression rings. With this construction the greater part of the explosive force is accepted directly by the connecting rod and the entire construction is intended to give light weight with good thermal conditions.

Referring to the crankshaft construction, it will be noted that two flywheels are used flanged to the counterbalanced crankshaft. The idea is to eliminate whipping of the shaft as the energy is stored up directly in the flywheel, without the necessity of the impulse passing through the entire shaft, thus causing a whipping action.

Lubrication is by force feed to the ball bearings, the overflow being caught by the four gutter rings and led through the drilled crank web to the connecting rod bearing, thence to the upper end of the piston through the copper tube within the rod.

A positively driven plunger pump keeps the engine base dry, forcing oil to a five-gallon tank. When the pump has cleaned out the base it draws in pure air and automatically maintains a pressure on the supply tank by means of a blow-off valve. The oil feed is connected with the throttle, thus adjusting oil supply to motor speed.

The entire design aims by means of large ports, positive timing, light-weight reciprocating parts and accurate balancing to avoid the difficulties of the higher rotative speeds and to show good performance in the upper ranges.

The Rostrum

Offset Cam Distributes Follower Wear

EDITOR THE AUTOMOBILE:—Some gasoline motor manufacturer has designed an engine with an offset between the center lines of the camshaft and pushrod, as shown on my sketch. This motor is L-head type, 3¼ by 5, and valve opening is about ¼ in., and motor speed from minimum to high is approximately 800 to 1800 r.p.m. If there is any advantage in the above mentioned valve mechanism, kindly fully explain it.

Flint, Mich. W. N. N.

—The advantage of the offset cam is that the cam tends to rotate the pushrod. The result is that the wear due to cam contact is distributed around the entire circumference of the circle of travel.

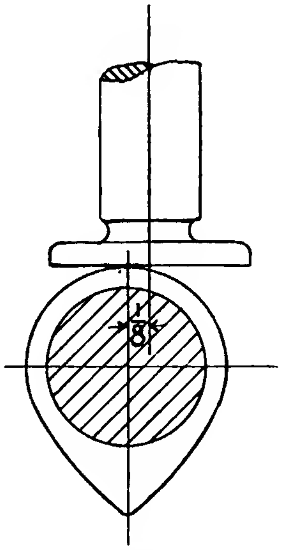


Fig. 1—Offset cam and follower

Field of Self-Lubricated Bearings

Editor THE AUTOMOBILE:—What are self-lubricating bearings?

2—Does this self-lubricating quality last as long as the life of the bearing?

3—For what special work are they used?

4—Are they fit for severe service, such as the crankshaft and camshaft bearings of a motor?

Washington, D. C. R. A. E.

—Self-lubricating bearings are those in which the frictional qualities of the bearing liners are such that they do not require the use of an additional lubricant.

2—Not always. For instance, in the case of wooden bearings where a treatment is given the wood by impregnation with a certain substance it is often necessary to renew the treatment. Bearings of phosphor bronze and compressed graphite such as are used on brake shafts are claimed to last the life of the car.

3—They have a wide variety of uses, for example: in friction shock absorbers of certain types, wood friction disks are employed which are self lubricating and in marine work the last bearing of the propeller shaft is lined with lignum vitæ. This is a wood with lubricating qualities. As stated, the phosphor bronze and graphite are used in brake work and often for spring eye bushings.

Blitzen Benz Not a Stock Car

Editor THE AUTOMOBILE:—Is the Blitzen Benz car a stock made car in more than one model or just a racer?

2—I have a 1914 model H Hupmobile in which the water boils. It does this after running only two miles. Would you advise installing a pump, and if so how can this be done? Also, what make would you advise for this?

The radiator holds about 20 qt. of water and am using Panhard medium oil in this car. Is this all right? If not, what would you advise?

Chester, N. Y. C. F. J.

—The Blitzen Benz is a racing car and not a stock design.

2—In checking up the motor to remedy the situation due to the boiling of the water the following steps should be taken:

1—See that timing is proper.

2—See that the valves are not riding. The proper adjustment is between 0.004 and 0.006 in.

3—See that spark is advanced as far as possible without causing a knock.

4—Make sure that there are no constrictions in the water passages and that the radiator is clean. The radiator can be flushed out with a solution of soda and then thoroughly irrigated by connecting a hose to the bottom and allowing it to run under city pressure. The same method should be used in cleaning the water-jackets.

5—Be sure that the carbon deposits are removed and that you are using a good grade of cylinder oil.

6—Be sure that the muffler is not clogged, giving excess back pressure.

7—Do not allow the clutch to slip nor the brakes to drag.

8—See that the gasoline mixture is not too rich and make sure that the carbureter is not flooding.

9—The fan belt must be tight so as not to allow the fan to slip while the motor is running.

10—Clean the oil screen so that the circulating system will be sure to operate properly.

Calculated Horsepower by Formula

Editor THE AUTOMOBILE:—Please tell me how to find the horsepower of automobiles?

2—What is the horsepower of a car that is 3¼ by 5 in.?

Jamestown, N. Y. K. B.

—The horsepower of a motor is calculated by squaring the bore, multiplying by the number of cylinders and dividing by 2.5.

2—The formula horsepower for a car having a bore and stroke of 3¼ by 5 in. is 16.90 for a four; 25.35 for a six; 33.80 for an eight and 50.70 for a twelve.

Kerosene Not Good for Radiator Use

Editor THE AUTOMOBILE:—Could coal oil be used in the radiator of Maxwell model 25 this winter instead of water?

Laurelville, Ohio. W. P. DeH.

—It is inadvisable to use coal oil in the radiator of a car. The first warm day will cause such rapid evaporation that serious harm is apt to be done the motor by overheating.

Carburetion Not More Complicated on the Six

Editor THE AUTOMOBILE:—I would like you to explain to me in what way six-cylinder carburetion is more complicated than on a four. In other words, why is carburetion more complicated on a six than a four? What is the reason for this? High authority claims that a six is not as efficient as a four for the same piston displacement. Why is this? What is it about a six that accounts for this lack of efficiency?

2—Is a six of standard make subject to vibration up to 1500 r.p.m.?

3—Is not a four-cylinder motor as satisfactory up to 300 cu. in. and 3000 lb. weight as any six?

Beemer, Neb. GROVER SHARP.

—Carburetion difficulties are hardly more complicated on the six than they are on the four. One of the reasons advanced for less thermal efficiency in the six than in the four is the fact that there is more cooling wall area per unit of displacement in the six than in the four. However, it is generally maintained by six-cylinder manufacturers that the gains in balance, etc., more than make up for the possible losses in thermal efficiency.

2—This you can readily determine by actual experiment. It all depends on how well the motor is balanced.

3—This is another matter of personal opinion. If one were better than the other to such a degree that the opinion was unanimous the other type would surely be abandoned.

Cutout of No Benefit to Motor

Editor THE AUTOMOBILE:—Kindly let me know through THE AUTOMOBILE of what benefit a muffler cutout is to a motor.

Hazleton, Pa. H. M. S.

—No direct benefit or harm results to the motor from the installation of a muffler cutout. Many motorists like to listen to the sound of the exhaust but it is unfortunately true that the use of the cutout is often abused.

Auxiliary Exhaust's Added Complications

Editor THE AUTOMOBILE:—Does any automobile manufacturer employ an auxiliary exhaust in the construction of their motor? If not why? It is used on some makes of stationary engines to advantage and would seem to be practical for use in automobile motors and particularly in those of the valve-in-head type. It would certainly relieve the valves of a considerable amount of heat due to the sweeping of the hot exhaust gases directly against them. I have reference to the vertical type of valve and would make for more complete scavenging of the cylinders of the burned gases and result in greater power and efficiency.

Webster, N. Y. G. J. A.

—No auxiliary exhaust valves are used at the present time. The reason for this is that it has been possible to design the exhaust valves to take care of all the gas flow. Besides, with one set of valves the manifolding arrangements are much simplified.

Balancing Single-Cylinder Vertical Motor

Editor THE AUTOMOBILE:—Kindly explain by sketch and description how to balance a vertical 4 by 5 high speed single cylinder four-cycle air-cooled motor. The flywheel is inclosed in the crankcase having a 9-in. diameter and weighs 30 lb.

2—What clearance would you allow for expansion in this motor using light alloy pistons?

Portland, Ore. A. W.

—Balance of a single-cylinder motor is effected by crankshaft counterweights and heavy flywheel to maintain the minimum variation in angular velocity of the crankshaft.

2—The clearances used with the light alloy pistons are about double those of the cast-iron type.

Compares L-Head and I-Head Motors

Editor THE AUTOMOBILE:—Will a 4 by 4½ valve-in-head motor develop more power than the same size poppet valve motor?

2—Will the above size engine consume more or less gasoline than the poppet valve motor?

3—How will a Knight motor, say 4 by 4½, compare with a poppet valve and valve-in-head motor as to gasoline consumption and power?

4—Will a poppet valve motor have the same compression as a valve-in-head motor?

5—Does it take more or less power to open the valve of a valve-in-head motor than the valve of a poppet valve motor?

6—If you had a poppet valve motor having the same size valves as a valve-in-head motor, which type of motor would develop more power and which would consume more gasoline?

Manitowoc, Wis. J. A. R.

—The probabilities are that the maximum power will be higher due to the more advantageous shape of combustion chamber.

2—There will be no material difference.

3—This depends on individual design.

4—This also depends on individual design.

5—About the same.

6—The efficiency would probably be a little in favor of the valve-in-head type due to the advantageous combustion chamber form. The whole question, however, is one of individual design, as a poor valve-in-the-head motor would not perform as well as a good L-head and vice versa.

Current Regulation of Delco Buick 25

Editor THE AUTOMOBILE:—How is the regulation of current taken care of in Delco system used on a model 25 Buick?

2—In assembling a Ford motor does it make any difference which side of the motor you place the connecting-rod which has the bolt through it at the top making one side heavier than the other?

Blanchard, Iowa. R. H.

—Regulation is taken care of by the inherent qualities of the field winding of the motor generator. This is a reverse series winding.

2—It makes no difference.

Timing of Rotary Valve in Elmore Motor

Editor THE AUTOMOBILE:—Please give timing of rotary gas valve in relation to the piston position on a 1912 model large four-cylinder Elmore.

2—What motor, if any, is interchangeable with the above, meaning four cycle motor? C. BROS.

Clarksburg, W. Va.

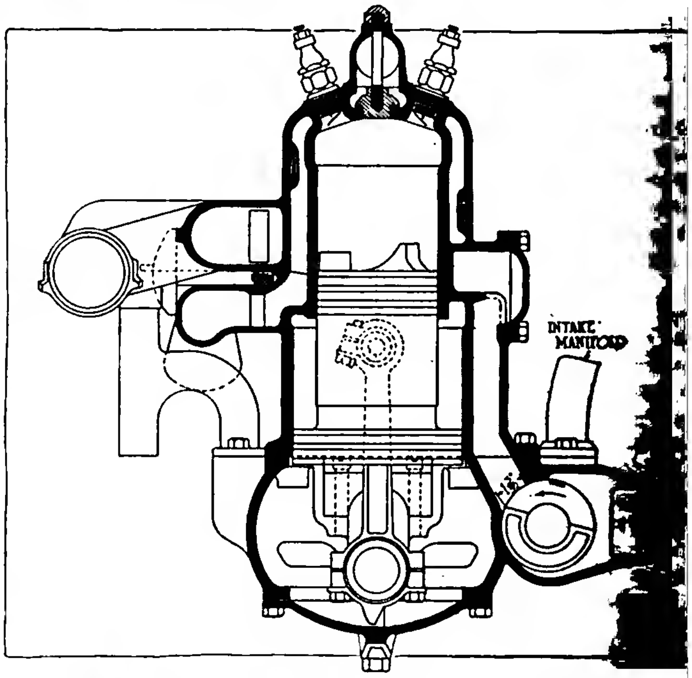

Fig. 2—Section through Elmore showing valve at lower center

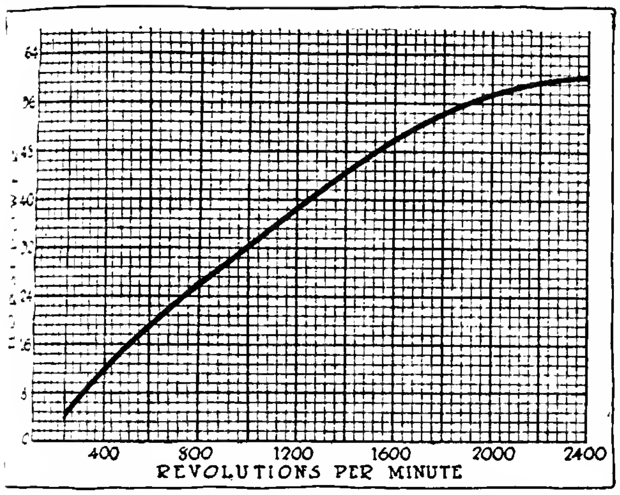

Fig. 3—Horsepower curve of Cadillac Eight for 1916

—The accompanying section of the Elmore motor in Fig. will give an idea of the timing.

—No motor of which THE AUTOMOBILE has any record is interchangeable with the Elmore. It is not difficult, however, to bolt or rivet a sub frame for installing another motor.

Can't Charge from Alternating Current

Editor THE AUTOMOBILE:—A man owning a Ford states that he is going to buy a storage battery and a regulator. He claims he can keep his storage battery charged from the magneto with which the car was equipped. Can that be done? What would it cost?

The battery is to be used for lighting only.

Adams, Minn. J. A.

—It is impossible to use any form of storage battery with a Ford magneto because the current produced by this magneto is alternating.

Wants Parts for Old Dragon Car

Editor THE AUTOMOBILE:—I have a Dragon car with a Buick M-17 rear end, 32 by 3½ wheels. Can I use to advantage 34 by 4 wheels?

2—If I have a plate ⅛ in. thick placed on the end of each valve plug, will I get any advantage from the higher compression?

3—What is best carbureter to use on this type of motor, the intake manifold has been shortened 3 in. to bring the carbureter higher and nearer the cylinders. Is that an advantage?

4—Did the Dragon firm make the motor? If not, whose make was it?

Trenton, N. J. W. R. D.

—The oversize tires for the 32 by 3½ are 33 by 4 and possibly you would save money and secure all the advantages by employing these tires instead of fitting entire new wheels.

2—No.

3—Any standard design of carbureter will be satisfactory. Shortening the intake is an advantage with the present heavy fuel.

4—Yes. You can secure parts for this car from the Philadelphia Machine Works, Philadelphia, Pa., or the Gerson Automobile Exchange, Philadelphia, Pa.

Grabbing Clutch Is Hard on Gears

Editor THE AUTOMOBILE:—We have a car which is continually stripping differential drive gears. The clutch is so savage that it is nearly impossible to start the car without jumping. We have used Neatsfoot oil and adjusted the tension on the springs under the leather and when you get it so that the clutch will take hold easy it spins so that you cannot get into the gears when the car is standing.

Have you any suggestions to offer that might be of benefit to us?

Portales, N. M. E. L. K.

—The clutch and universal assembly used on this model has to be treated very carefully in order to secure satisfactory operation. The best thing to do is to adjust the insert springs so the clutch will engage smoothly and then put on a clutch brake which will slow it up when fully disengaged. This clutch brake must be so located as to have no effect on the clutch until it is thrown out to the limit. If the clutch brake is located so close that it serves as a resistance when it is not fully disengaged it will make shifting from first to second and from second to third very unsatisfactory. Even with this adjustment it will be necessary for the operator to be very careful in the action of his feet when shifting gears. Another suggestion is that the spline shaft between the universal be kept well lubricated.

Valve Timing for Model E Maxwell

Editor THE AUTOMOBILE:—Please give the valve timing which will give maximum power for model E Maxwell.

Hickory, N. C. G. G. W.

—Inlet valve opens 15 deg. late and closes 40 deg. late, these dimensions being 2.387 and 6.633 in. respectively on the flywheel. The exhaust opens 40 deg. early and closes 10 deg. late or 6.633 and 1.691 in. respectively on the flywheel.

Charging Battery from 550-Volt D. C.

Editor THE AUTOMOBILE:—Would it be possible to reduce a 550-volt D. C. current to a voltage suitable for recharging storage batteries such as are used on automobiles for starting and lighting purposes?

2—Could you furnish me a sketch or drawing showing how this could be done with the least expense? Would like to have the most simple method possible as I wish to do the installation myself.

Windber, Pa. R. M. S.

—In charging a starting and lighting battery from a 550-volt D. C. circuit it would be necessary to install sufficient resistance so that the drop across it would be 542½ volts for a 6-volt battery, 535 volts for a 12-volt battery, etc. In the first instance you are utilizing only 7½ ÷ 550 of the energy and in the second case 15 ÷ 550, or 1.36 and 2.72 per cents respectively. It is seen from this that this would be an extremely wasteful method of charging batteries. It can, however, be done, and about the simplest method is to use six strings of 32 c. p. carbon lamps. Strung in groups of five across the positive battery and positive 550-volt D. C. current line. One string of five lamps is lighted for every ampere of charging current desired. The lamps used are the regulation 110-volt 32 c. p. carbon lamps screwed in porcelain sockets, mounted on a board, covered with transite or asbestos board. A wiring diagram of this is given in Fig. 4.

Details of the Cutting Model T

Editor THE AUTOMOBILE:—I have a 1913 model T 35 Cutting car geared 3½ to 1 of which you will kindly answer the following questions:

1—The S. A. E. rating?

2—Probable cause of the car not being able to make more than 35 m.p.h. seemingly at best?

3—The cause of the clutch rattling when disengaged and car is running idle?

4—Where parts can be obtained at lowest prices for said car?

5—Whether car is equipped with Wisconsin engine and whether parts for same can be obtained from Wisconsin Motor Co.?

Danielsville, Pa. W. L. P.

—The S. A. E. rating of this car is 25.60. It had a bore of 4 and a stroke of 5 in.

2—Probably leaky pistons, worn cams, worn timing gears, worn cylinders and loss of compression due to the above and possibly to improper valve seating.

3—Clutch disks worn and also worn keys on clutch drum.

4—Puritan Machine Co., Detroit, Mich.

5—Answered under question 4. THE AUTOMOBILE has no record as to the manufacturer of the motor.

Cadillac Horsepower Curves Are Similar

Editor THE AUTOMOBILE:—Kindly give me the power curves of the 1915 and 1916 Cadillac eights?

Burlington, Vt. H. W. F.

—The horsepower curves for the 1915 and 1916 Cadillac eights are similar. The curve is shown in Fig. 3.

Lamps Use About One Watt per C.P.

Editor THE AUTOMOBILE:—Which consumes more current, a 32 c.p. nitrogen tungsten lamp, 7-volt, or a 15 c.p. mazda tungsten, 7-volt?

Montclair, N. J. S. L. G.

—The 32 c.p. lamp will consume about double the current of the 15 c.p. On the tungsten lamps the current consumption is just about 1 watt per c.p. but on the nitrogen lamp it is slightly less than 1 watt.

Oxygen-Carbon Burning Will Not Harm Piston

Editor THE AUTOMOBILE:—Is the oxygen decarbonizing system successful and will it affect aluminum pistons or piston rings?

St. Louis, Mo. A. R. C.

—The oxygen method of removing carbon is successful. It will not harm aluminum pistons since the action, after the burning has once started, is catalytic and local. The instant the carbon is burned off in a certain locality the combustion in that area ceases.

Sand Hole in Piston Causes Misfiring

Editor THE AUTOMOBILE:—I have a Premier 6-60 1912. When running idle number six cylinder will not fire, but when given more throttle, it will and runs smoothly when speeded up. There is the same compression in this cylinder as in the others.

I have put more tension on exhaust spring so there is not any chance of lifting it on suction stroke. I have put felt washer on intake valve stem in case there was false air getting in around the stem, also put felt washer on number five valve stem. The spark plug is firing all right, at least it does not become dirty. I have changed the plugs from another cylinder, without results. I have also decarbonized and ground the valves.

2—My Remy generator has stopped charging. I have tested the fuse and found it all right. I took the relay off, cleaned the brushes and commutator then when it was started it charged, but the engine sat idle for a day and when started again it failed to charge. On pressing the platinum points together on the automatic relay, it did not show any discharge on the ammeter, but when lights are on the ammeter shows discharge. Will be heartily grateful for anything you may be able to offer on this subject.

Bangor, Me. P. R. W.

—This probably is due to manifold trouble, if the motor is in sound condition throughout. The manifold on the 1912 car may have acted satisfactorily with the gasoline secured at that time, but with the present heavy grade the probabilities are that a good firing mixture is not obtained at idling speeds in the No. 6 cylinder. It is suggested, however, that before giving up the idea of remedying the trouble you remove the piston from No. 6 cylinder and examine it for sand holes, especially under the rings, and also examine the rings for bearing surface around their entire circumference.

2—Although you do not give sufficient data to diagnose accurately the trouble the majority of similar complaints are due to loose connections. Therefore, it is suggested that the first possible cause of the trouble is a break in the generator charging line. A loose connection at the relay or a loose or broken connection or broken wire in the generator charging line will, of course, prevent the generator from charging the battery and would prevent a discharge reading on the ammeter when the relay contact points are placed in contact.

You state that you have examined the relay fuse and found it all right. However, it is suggested that you pinch the fuse clips a little closer together to be sure that these clips are making good contact with the ends of the fuse.

As a third possible cause of this trouble, there may be a small quantity of dust or dirt between the relay points. A very fine piece of sandpaper should be drawn lightly between these points and all dust carefully removed. A very small quantity of dust or dirt lodged between the points might prevent them from making good contact and would therefore prevent the generator from charging.

Kerosene Carbureter Details Not Available

Editor THE AUTOMOBILE:—Kindly give me a description and cut of the Holley kerosene carbureter as stated in THE AUTOMOBILE of Sept. 20, page 584, which is used on the Ford tractor.

2—Kindly give cut of the Ellmore two-cycle engine.

Barberton, Ohio. F. S.

—Details of the Holley kerosene carbureter will not be available until the device is put on the market. This will probably be coincident with the appearance of the Ford tractor.

2—The Ellmore two-cycle motor is shown in section in Fig. 2. Its operation is readily understood from the drawing, as it is a two-cycle motor with a simple rotary valve gas distributer.

Heavy Gasoline Makes Starting Difficult

Editor THE AUTOMOBILE:—I have been unable to start my Buick model 16 on a quarter turn, even when my valves are ground in good and tight, unless it is warm. What is the cause of this?

Lawrence, Mass. C. E. C.

—This is probably a matter of low-grade fuel. As the quality of the fuel becomes poorer the motor will become naturally harder to start.

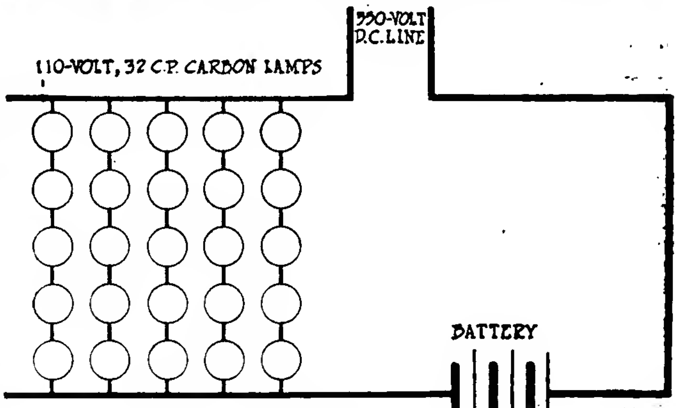

Fig. 4—Charging 3-cell battery from 550-volt D. C. line

British Trade in Strong Condition

War Orders Maintain Profits and Often Increase Them—Sunbeam Co. Earns 89 Per Cent

LONDON, Jan. 15—After one year's operation under war conditions, the British motor industry finds itself in a remarkably strong financial condition. It is only possible to judge with any degree of certainty the strength of those companies registered under the limited liability law and, in consequence, having a published balance sheet. In practically every case the net profit earned during the financial year ending on or about December, 1915, is greater than the earnings for the year 1914. In other words, the war has not had an adverse influence on the British automobile industry.

Sunbeam Profits Huge

The most notable balance sheet is that of the Sunbeam company, which shows a profit of more than $1,200,000, and has paid a dividend of 25 per cent free of income tax. At the same time the company has placed $600,000 to reserve, bringing this account up to $1,100,000, and has carried forward a sum of $378,335. The paid-up capital of the company is $1,350,000, so that the profits of the year bear a very important relation to the capital employed. Further, the amount placed to reserve fund is larger than the net profit in any year in the history of the company, while the amount carried forward exceeds by $25,000 the profits for the year immediately preceding the war.

Tables showing stock quotations of leading British automobile companies on July 27, 1914, and on Jan. 12, 1916. In each case the nominal value of the stock is $4.80. The tables also show the last dividend paid before the war, the last paid since the war, net profits, general reserve funds, etc.

The B. S. A. balance sheet, which also includes the Daimler company, is another conspicuous example of the prosperity of the British automobile industry. The company shows a profit of more than two million dollars and pays 20 per cent, compared with 15 for the previous year. The increased strength of the company is not revealed, however, by the dividend paid to stockholders, for the earnings have increased from $950,000 in the 1914 financial year to more than $2,040,000 during the last year. In addition to this, the company has put nearly two and a half million dollars to the general reserve fund.

Another case which calls for attention is that of the Darracq company, which is registered under English laws but has its factory in France. It is the only one on the adjoined list having a factory abroad. After paying no dividend for four years, the Darracq stock has yielded 7½ per cent, which is very much less than the directors might have paid out had it not been for the uncertainty regarding the future and the desire to strengthen the financial position. Thus the company has placed $250,000 to general reserve, bringing this account up to its original figure of $750,000; it has placed $269,840 to special reserve and has carried forward $85,720.

Dunlop Co. Does Well

The Dunlop Rubber Co. heads the entire list of automobile and kindred firms with a net profit of $2,058,195, being a net increase on the previous year's trading of $185,000. Here again the dividend is not by any means as high as would have been in ordinary times, the directors seeing the necessity of making substantial provision against possible lean years which may follow the war.

In the few cases where the dividend this year is less than for the previous twelve months, it can in nearly every instance be attributed to special circumstances, as, for instance, foreign investments, for which huge depreciations have to be allowed, or losses through branch houses or goods being held by the enemy. These, however, bear a very small proportion to the whole. It should be noted, too, that many of these balance sheets include the first two months of the war, when owing to failure to realize the extent and possible duration of the conflict some of the factories were standing idle or running below their full capacity.

Financially the position of the English and the French automobile manufacturing concerns is unusually strong, but this does not imply complete satisfaction on the part of those holding interests in them. The government scheme to tax a large proportion of the excess profits is not to the taste of interested parties. One outcome of this has been that the Darracq company has formed a French company to acquire the French factory, the whole of the stock, with the exception of the small amount necessary to comply with the law, being held by the British company. The main advantage of this is that the French taxation of war profits will be lower than that of England; it will also facilitate the firm in a certain degree in the securing of French war contracts. Under the conditions brought about by the war, English firms with factories in France—there are about half a dozen of them in the automobile industry—were liable to taxation both by the French and by the British.

The greatest strength of the British motor industry is not revealed in the summaries of its financial situation. While reserve funds are being built up and adequate dividends are being paid on common stock, immense sums are being expended on improvements and additions to the factories. The new plant put down since the war costs more than in normal times, but in most cases its cost will be wiped off by the war contracts already in hand. The result is that the end of the war ought to find the automobile industry sounder financially than at any previous period, and at the same time in possession of more modern and more completely equipped establishments.

Despite this, British manufacturers are not particularly joyful. There is a haunting fear that the end of the war will find America in possession of the home and colonial markets; the goodwill and trade names which have taken years to build up, are gradually diminishing until they may become insignificant factors. In this connection the war is tending to place the smallest firm on a level with the best. All, big and little, have to face the fact that American makers who would normally never have found a footing on the market, have now secured a strong position and will have to be competed against. In consequence, the feeling toward the American automobile industry is far from cordial. Of this more can be stated later.

Vesta Electro-Mechanical Clutch Proves Good on Trial

By Darwin S. Hatch

CHICAGO, Feb. 4—Not uncommonly, new ideas that seem to offer much when viewed on paper fail, in an actual trial, to live up to the expectations aroused by a study of their plans. Constructional difficulties sometimes make it impossible to get expected results by the practical application of a good theory. Hence, it is a pleasure to record the results of a drive in a car equipped with the new Vesta centrifugal electric clutch which was described in THE AUTOMOBILE for Jan. 27, of which the design promised a number of advantages over conventional transmission systems in the way of easier control and smoother running.

Actual handling of the car equipped with the new system proved a revelation as to what extent it is possible to convert the irregular impulses of the gasoline engine into smooth, even torque at the rear wheels.

Clutch Combines Generator

To recall the features of the design which was explained in detail in the earlier issue, the Vesta centrifugal eelctric generating clutch is a combined motor-generator which replaces the clutch, lighting generator and starting motor of the conventional car. There is a gearset which offers two or three speed reductions for emergency use, but under ordinary conditions, starting and running are on direct drive.

The idea of the new design is the utilization of a combination of the electromagnetic drag between the armature and fields of any electrical machine with a direct friction connection, such as is obtained in the ordinary clutch. The armature of the instrument constitutes the flywheel of the engine and the field is mounted on the forward end of the propeller shaft with a unique constant-mesh gearset between it and the propeller shaft. The fields are within the armature, so that the commutator is internal, and the brushes, which revolve with the driveshaft, press outwardly against the commutator. They are mounted in such a way that they press more heavily against the commutator as the speed increases.

At low speeds, or whenever the resistance of the rear wheels is too great for the centrifugal force to prevent slippage between brushes and commutator, the fields will start to revolve more rapidly than the armature and this difference in speed causes a current to be generated in the armature. This current flows around the field poles, making magnets of them, the magnetic drag thus caused drawing the armature around with the field. The greater the slip, the greater the magnetic pull. The excess current produced by variation in speed between armature and field goes to keep the battery charged. No current for the operation of the clutch is taken from the battery except when the clutch is operated as a motor to crank the engine.

In view of the fact that there is no mechanical connection between engine and flywheel at low speeds, it is to be expected that the action of the car would be exceedingly smooth, and such proved to be the case. Even when starting with a cold motor, which missed and bucked as cold motors are wont to do, only the sound of the irregular explosions apprised us of the fact that the engine was not working smoothly. So far as the propulsion of the car was concerned, we might have had twelve cylinders under the bonnet instead of intermittent three and four.

The first view of a car equipped with the new system did not indicate much out of the ordinary. There was a slightly larger battery than usual. Also on the running-board there was a small metal box, which later was found to be the switch unit. The steering column offered the most to be seen. Under the steering wheel was a metal box, from the sides of which protruded four large buttons, about half the size of doornobs. There was neither gearshift nor emergency brake lever. Otherwise the car was normal.

Handling Is Easy

The handling of the car was very simple and easy, an overgrown button in the form of a knob was pulled out and the engine started. We pulled a second, or neutral button, which left the car ready to be started on high; then stepped on the accelerator and the car moved off, picking up in speed as the throttle was opened—and accelerating with surprising rapidity.

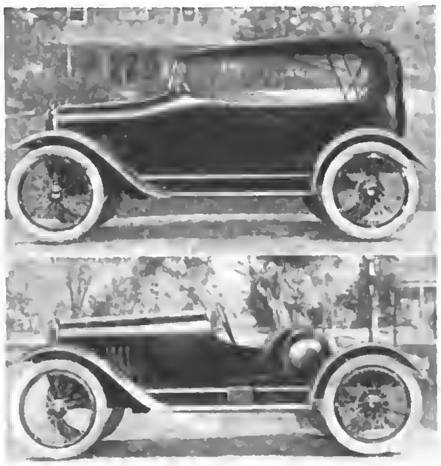
Then we tried to stall the engine. With a foot on either brake pedal and still on high speed we brought the car almost to a dead stop and still the engine kept running, even with the throttle fairly well closed. It is impossible to stall the motor by applying the brakes.

Running at 25 m.p.h. on high, we pushed another knob and without the slightest sensation of a jerk we were in low, the only evidence of the change being the slight click of the solenoid switch and the increased motor speed. There was no careful slowing down, holding out of clutch, shifting a lever, accompanied by grinding of geers, speeding up the engine, letting in the clutch, etc., that usually is necessary in dropping from a high to a lower speed with the conventional transmissions—we simply pulled knobs on the steering column and that was all. The gearset is operated electrically by knobs on the control box mounted on the steering column. Also it is of the constant-mesh type, so the gears

(*Concluded on Page* 299)

ACCESSORIES

Universal Specialties for Fords



Ford cars fitted with Universal Car Equipment Co.'s special bodies, wheels, fenders, etc. The tourabout, above, has a special top and windshield

THE Universal streamline tourabout body for Ford cars is of reinforced heavy gage steel, and the upholstery is deep and comfortable with spring cushions. Seats are wide and legroom is ample. Guaranteed Boston Artificial Leather Co. fabric is the upholstery material used and the equipment includes robe and foot rails, scuff plates, carpet, lock plates and knobs. Fifteen painting operations insure the durability and high quality of the finish, the standard color being black with gold stripe, with special colors $10 extra. The mohair khaki one-person top and rain-vision ventilating windshield, illustrated, are made especially for this body and will not fit the regular Ford type. The body sells for $150; with the top and windshield as illustrated, $38 extra. The Universal streamline radiator, of heavy steel well enameled and finished, with extra large cooling area, sells for $45, f.o.b. Detroit, including special crank, hood clamp brackets, bolts, etc. The Spranger wire wheel recently described in THE AUTOMOBILE is sold for $35 for a set of four wheels and five rims in red, green, black or yellow, including a rim wrench. These wheels, which are easily attached without bolts, front wheels coming complete with ball bearings and rear machined to proper taper and key seat, may be had in special colors for $5 extra. The special crown fenders illustrated sell for $14 a set.

The Universal streamline raceabout body for Fords, illustrated herewith, is similar in material and construction to the tourabout, having deep, comfortable upholstery. This body, finished in red with black trim, hood and fenders being black and radiator black or nickel, sells for $100, including 15-gal. fuel tank and spare tire carrier. Special colors are $10 extra. Radiator and wire wheels, as described, may be fitted with this body.

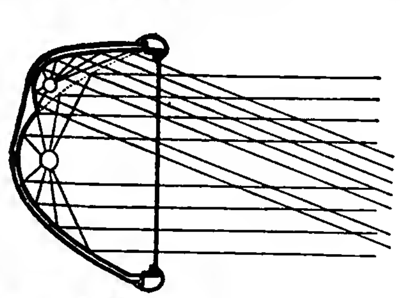
Another Universal accessory is the one-person top for the regular Ford body, which is of the best material and easily raised or lowered. With Jiffy or plain curtains, rubber cloth, mohair or khaki, including top boot, this top sells for $30. —Universal Car Equipment Co., Detroit, Mich.

Liquid Lustro Oil

This body polish is intended to prevent varnish from drying and cracking and is also claimed to neutralize the effects of alkaline soaps often used in washing cars by garagemen. The makers state that the polish may be used with impunity on any body surface as it will not injure lettering, crests or other ornamentations. The oil sells for 25 cents per 6-oz. bottle or 8-oz. can, or for 45 cents per pint can or 85 cents per quart.—Kenny & Moore, New York City.

Miller Double Focus Headlight

A new arrangement by means of which the dimming problem is handled by a double focus reflector and two lamps is illustrated herewith. The larger of the two lamps is intended for use only in country driving. The light from this lamp is directed horizontally and gives effective illumination of the road for a distance of 300 ft. or more according to the candlepower used. The smaller lamp, which is also in focus, gives a light of lesser strength and is directed downward at an angle so that the road is illuminated ahead of the car for 75 or 100 ft. No light is projected above the level of the lamp. In passing another vehicle the dim light can be switched on without removing illumination from the road.—W. M. S. Miller, Milwaukee, Wis.



At the left is the Miller double focus headlight, its principle of operation being illustrated above

Johnson's Cleaner

This cleaner, which is for use either with or without Johnson's prepared wax, is claimed by the manufacturer to entirely remove all stains, discolorations, scum, road oil, tar and grease from a car. Even spots that have been ground in and scratches on the surface which seemed permanent are said to disappear at once upon application of the cleaner. The cleaner cannot possibly injure or scratch the varnish, simply cleaning it so that a coat of the prepared wax will produce a high finish. For old cars, both the cleaner and wax should be used, the cleaner being applied two or three times a year and the wax every six or eight weeks. For new cars the wax is sufficient to protect the finish from the ravages of wear and weather.—S. C. Johnson & Son, Racine. Wis.

Bosch Systems for Small Cars

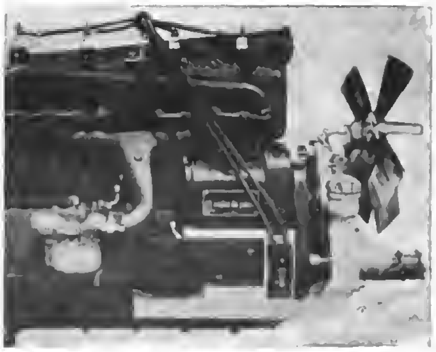
The ignition-lighting system for small cars combines the qualities of an independent high-tension magneto and a direct current, shunt-wound generator. Except that the two units are inclosed in one housing, they are distinct, either operating independently of the other, while the non-operation of one does not affect the other. The whole unit is 9¼ in. long overall, excluding the shaft, 8½ in. high and 4¾ in. wide, the weight of the unit being 25 lb.

The connections of the ignition section of the device comprise only the cables between the distributer and the spark plugs. There is no coil, no separate timer, no complication of wiring, etc., the battery being used only in connection with the lighting section of the device.

The generator section is a direct current shunt-wound type while charging, but has an extra series field connected in series with a lighting switch. Thus all the lighting current passes through the series field, increasing the output of the device when running under load. The wiring is simple, consisting of a cable from battery to generator and another cable from the generator to the distribution switch. The normal capacity of the generator is 10 amp. at 7½ volts, equal to 75 watts.

The starting unit is separate and entirely independent, being mounted as illustrated at the left side of the motor,

Bosch starting motor for small cars, showing mounting on Ford flywheel



Bosch lighting and ignition system for small cars. Note horizontal magnet

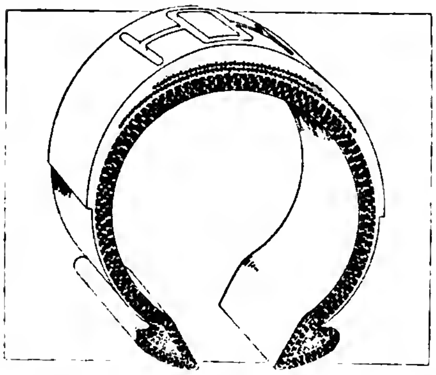
where it acts on a special split gear ring clamped to the flywheel.—Bosch Magneto Co., New York City.

Combination Tires

Combination tires are made with plain tread and in two styles of non-skid tread, both of the latter having depressed markings. Several layers of fabric are employed and in addition a double layer of fabric protects the cushion strip. The tread is of black rubber and a specially hand-constructed bead is employed which is said to be proof against rim-cutting or coming off the rim. Some of the list prices are as follows:

Size	Plain Tread	Hold-On Tread
30 x 3	$10.85	$12.70
30 x 3½	14.15	16.20
34 x 4	23.60	27.10
36 x 4½	33.35	39.20
37 x 5	38.85	48.90

The accompanying illustration gives an idea of the non-skid tread.—Combination Rubber Mfg. Co., Bloomfield, N. J.

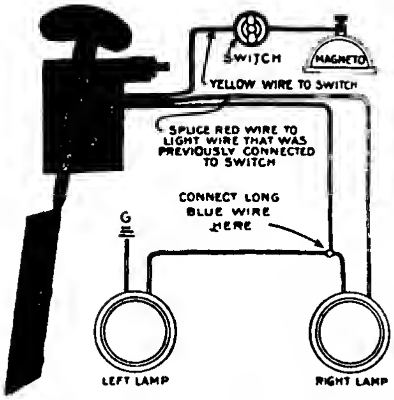


Combination Rubber Mfg. Co.'s depressed non-skid tread

New York Headlight Controller

With this advice the makers claim a Ford magneto can be made to deliver a brilliant strong light even when operating at the lowest speeds at which the car can run. The most novel feature of the device consists in the principle of utilizing the entire electrical output of the Ford magneto at all speeds below approximately 15 m.p.h. for the one headlight located on the left side of the car. Above this speed the two lights come into use, and at still greater speeds a resistance is automatically thrown into the circuits to prevent the lamp from becoming burned out. Every operation of the device is automatic, the driver having nothing to do with the system after it is once installed. The device depends for its operation upon the draught of air created by the fan, the instrument being placed about 8 in. to the rear of the fan, where it is secured to the top of the cylinder by means of one of the cylinder bolts. An arm which is counterweighted carries on one end an aluminum disk, which is in line with the left half of the fan. The air from the fan causes this disk to move away from it in direct proportion to the speed at which the motor is running. An adjustable spiral spring tends always to operate the arm and disk in the opposite direction. The arm carries a contact which forms a sliding connection or contact on three similar contacts secured in the solid metal base.

When the engine is turning at speeds below 15 m.p.h. the arm establishes connections to the one left lamp. As the speed increases to a point where the magneto is able to supply the two lamps with current, the air draft from the fan is sufficient to move the arm to the second contact, which cuts in two lights. A greater speed causes the device to throw in a resistance coil which prevents their being burned out. The device is simply installed.—New York Coil Co., Inc., New York City.



New York headlight controller for Fords

Harper Trailer

These trailers are built as No. 10, which has Timken roller-bearing axles for speeds up to 35 m.p.h., and No. 12 with plain spindles for speeds up to 20 m.p.h. Both models are 8 by 40 by 72 in., inside measurement, either with or without flareboards. Sills are ash and panels yellow poplar. Wheels are 34 by 1⅛ or 1¼ in., either steel or solid rubber tires being fitted. Axles are 1⅛ in., with a carrying capacity of 1000 lb., or 1¼ in., having a capacity of 1500 lb. Standard tread is 56 in. With steel tires the trailer weighs about 280 lb. and with rubber tires about 295 lb. Crating for shipment adds 100 lb. The Harper patent universal joint connection, as illustrated, is used. Standard finish is black with blue striping with lettering at extra cost, if desired. Prices are as follows:

	Steel Tires		Rubber Tires	
Trailer	1⅛-In.	1¼-In.	1⅛-In.	1¼-In.
No. 10......	$60	$62	$65	$68
No. 12......	52	53	57	68

Casey Running-Board Brace

By the use of the Casey brace the running boards of a Ford are prevented from sagging when heavy weight is placed on them. The brace forms a triangular suspension and prevents buckling of the cross rod that runs from one board to the other. It is easily applied without drilling or fitting and without special tools. The brace sells for $2.—Kansas City Automobile Supply Co., Kansas City, Mo.

The Price of Steel and of Automobiles

IT is an almost universal law of commerce that the price of an article bear some relation to the demand for it. If the demand is small the price is high, because it is troublesome to make a thing not often desired. If the demand is steady, competition enters the field and prices come down, reaching a level fair to the manufacturer and to the ultimate buyer. If, after a period of steady and well balanced supply and demand, the latter should suddenly increase an hundredfold, then the price goes up, because the more ardent purchaser willingly offers a premium for the goods he needs.

So to-day is the case of the steel market. Steel, the staple product of America, is in ever-increasing demand, but the curve of demand is more like a flight of steps, or the approach to some great mountain peak, than it is like a well-graded hill. When the country is prosperous, when everyone has money to spend, then the demand for steel is high. When trade is bad, when money is short, then the demand for steel falls off.

At the present moment we see the demand for steel at a fury never before attained, and for *two* reasons. One reason is that Europe's need has caused an immense increase in the exportation of steel products, and the other, *which is the greater of the two*, is that the prosperity *begotten of that exportation* calls for more and more steel to cope with the domestic demand begotten of the prosperity of the U. S. A.

Look on one hand and we see great manufacturing communities earning more money than ever before in history. These same communities, prosperous and with overflowing bank balances, turn naturally to the automobile as a most desirable thing to buy with a portion of their surplus and unexpected wealth.

Look on the other hand and we see the automobile manufacturer distressed that he has to pay more for steel in order to supply the demand on him created by the prosperity of those other persons who have gained their ability to buy automobiles by reason of the prices which other people are willing to pay for steel in other forms.

Examine the position of the employees of a shell factory. They are prosperous because of the foreign demand for the product they are making. Being prosperous they desire to possess automobiles, and the automobile manufacturer finds that the prosperity which creates the demand in this way also has increased the price he has to pay for steel.

Worth Is Not Price

A diamond has no market price; it is worth merely what people can be found to pay for it. In prosperous times diamonds are worth far more than in times of want. In a general trade slump the Kohinoor itself might be worth but a tenth of what it would fetch if put up to auction in times such as those we are enjoying to-day.

Prosperity is a good thing; none but a misanthrope can debate the question, but like most good things it has its price. A manufacturing country desires exports, and more exports, for exports represent direct money earned by the country as a unit, and if a country as a unit is exporting in enormous excess over its imports it is piling up wealth, so long as it obtains a proper price for the goods sent overseas.

America to-day is drawing from Europe incredible sums of money. The impoverishment of Europe is the wealth of America, so if American automobiles are to cost a trifle more the balance still remains well upon the credit side of the ledger. We are all making *much* more money either directly or indirectly, so it is rational to pay a *little* more money for our automobiles, since our very prosperity is the reason for that slight increase in price.

In the past six months we have seen automobile manufacturers decreasing prices in order to tempt a larger market and to be able to increase their outputs. To-day it is clear that the outputs would have been increased just the same without the drop in prices. Obviously then, the wise thing to do is to return all the way or part of the way to the old prices, till such a time as the price of steel decreases. Give the public the credit for a reasonable intelligence and an ability to understand a state of affairs that is making them, collectively, prosperous beyond all dreams.

Kansas City Show Is Largest on Record—Huge Crowds at Opening

Show Claimed to Have Larger Floor Area than Chicago—Exhibits Valued at $3,000,000—Tractor Show, Held Simultaneously, Also Attracts Many Visitors

KANSAS CITY, MO., Feb. 8—The annual motor show of the Kansas City Motor Car Dealers' Association opened to-day in the J. I. Case Building, Twenty-first Street and Broadway, with ninety-six motor car exhibitors and fifty-six accessory dealers having space in the four floors given over to the showing. Officers of the dealer association point out that the Kansas City show has twelve more car exhibitors than the New York exhibition and, using 140,000 sq. ft. of floor space, exceeds in size the recent Chicago show.

The show is the largest in history, with 192 vehicles. There are thirty-two commercial vehicles and fifteen electrics. Many dealers have already arrived from western Kansas, Oklahoma and northern Texas. Many retail sales were reported to-day in spite of cold weather, and much larger attendance than last year is looked for. Buying has been better last month than a year ago. Closed car business has increased heavily. A very large crowd appeared to-night, all four floors of Case Building being crowded.

"Kansas City for the last three years has been the largest motor car distributing center in the United States," E. E. Peake, secretary of the association, explained. "This, however, is the first year the show has been the largest in America."

The Kansas City Tractor Club also opened its first annual show, in a big tent on the Union Station Plaza, to-day. It has twenty-six tractor exhibits and forty-nine accessory makers, using 40,000 sq. ft. of space, and opened with good crowds.

The two shows this week, it is predicted, will bring from 50,000 to 60,000 visitors to Kansas City from western Missouri, Kansas, Oklahoma, southern Nebraska, northwestern Arkansas, and northern Texas, which is, roughly, the district served by the distributing agencies here. More prosperous this year than for several seasons, dealers expect heavy sales throughout the territory and already the hotels are crowded by the incoming visitors.

Convention Hall here has housed the show every previous year. But despite the fact that it was large enough to hold the biggest crowd that heard President Wilson on his recent swing through the Central West, it is too small for the motor exhibit. The Case Building, an eight-story warehouse structure near the new Union Station, was obtained this year, as it offered more space and probably will be retained for future shows.

The exhibits at the show are given a valuation of $3,000,000—the Southwest this year will pay attention to nothing that does not speak in millions.

The first floor in decorations is strictly American, the second modeled after the Monte Carlo gardens, the third has been named the Casino de Vichy, and the fourth floor has been converted into a Japanese garden.

Jordan Motor Car Co. Takes Detroit Office

KENOSHA, WIS., Feb. 8—E. S. Jordan, president of the new Jordan Motor Car Co., announced to-day that an engineering office has been established in the Goldberg Building, Detroit, where preliminary design work of the new car is being carried out. The company has not decided on a factory location as yet.

To Build Entz Transmission in Fort Wayne Plant

NEW YORK CITY, Feb. 8—The Fort Wayne plant of the General Electric Co. is being tooled up to manufacture the Entz transmission in large quantities. The Entz Motor Patents Corp., which was organized primarily to own the patents known as the Entz patents, covering an electric transmission unit, has also acquired other patents owned previously by the General Electric Co., which has acquired a substantial interest in the Entz corporation.

Studebaker to Redeem 5 per Cent Serial Gold Notes

SOUTH BEND, IND., Feb. 8—The Studebaker Corp. has given notice that it will redeem on March 1, 1916, all of its outstanding 5 per cent serial gold notes by the payment of 101½ per cent of the principal thereof, together with the accrued interest thereon. After March 1, 1916, all interest on these notes will cease.

Kelly-Springfield Tire Has $1,706,744 Balance for Dividends

NEW YORK CITY, Feb. 8—The Kelly-Springfield Tire Co. reports for 1915 a balance for dividends of $1,706,744, equal to 29 2/3 per cent on the $4,834,000 common stock, against 23 1/5 per cent on $4,000,000 the previous year. The gross profits were $2,880,080 as against $2,203,761 in 1914.

The balance sheet, as of Dec. 31 last, shows cash on hand of $705,051, against $380,415 in the corresponding period a year ago; total current assets of $3,581,605, against $2,717,405 a year ago and total assets and liabilities of $11,607,761, contrasted with $10,525,153 on Dec. 31, 1914.

The report for the year ended Dec. 31, 1915, is as follows:

	1915	1914
Gross profit	$2,880,080	$2.203.761
Oper. expenses, etc.	1,195,874	1,014,016
Net income	$1,684,206	$1,189,745
Other income	22,538	16,476
Balance for dividends	$1,706,744	$1,215,144
Dividend, sink. funds, etc.	727,664	373,451
Surplus	$979,080	$841,693
Previous surpl's adjusted	1,147,659	292,946
Total surplus	$2,126,739	$1,134,639

Studebaker Reduces Hours

SOUTH BEND, IND., Feb. 8—Effective March 1, the regular working hours in the local plants of the Studebaker Corp. will be reduced from 55 to 50 hr. a week, divided into 9 hr. a day for 5 days, and 5 hr. on Saturday. In order to adjust wages to the new working hours all piece rates and hour rates will be increased 10 per cent.

This action affects about 4000 men and will cost the corporation about $360,000 per annum. The present pay roll is about $300,000 a month.

Princess Motor Car Co. Capitalized at $1,000,000

WILMINGTON, DEL., Feb. 7—The Princess Motor Car Co. of Detroit, Mich., has been incorporated under the laws of Delaware, with a capital of $1,000,000, to manufacture, sell and deal in and with motor cars and all parts. The incorporators are O. C. White of Detroit, and Isaac N. White and Frank W. Barbee, both of Pittsburgh, Pa.

Hathaway Pres. Stanley Belting Corp.

CHICAGO, ILL., Feb. 8—C. E. Hathaway has resigned as Chicago manager of J. H. Williams & Co., maker of drop forgings, and has been elected president of the Stanley Belting Corp., Dundee, Scotland, with headquarters in Chicago.

A. L. Whittemore, also formerly with the Williams company as assistant to Mr. Hathaway, has been elected vice-president. John Laurence was re-elected secretary. A. G. List was elected treasurer.

Rankin Heads Mahin Advertising Co.

CHICAGO, ILL., Feb. 8—J. L. Mahin, founder of the Mahin Advertising Co., has sold his interests to W. H. Rankin, and retires at once from the presidency of the organization. Mr. Rankin has been vice-president of the company during the past seven years.

S. A. E. Sections Expect Good Meetings

Detroit and Indiana Sections Anticipate Large Attendance at February Gatherings

New York City, Feb. 7—On Feb. 16 "The Trend of Automobile Design" will be the paper read before the Detroit section of the S. A. E. by A. Ludlow Clayden, Engineering editor The Automobile, and on Feb. 25 F. A. Cornell will read a paper entitled "Anticipating Complaints" before the Indiana section.

The Detroit paper consists of a candid criticism of the chassis and cars seen at the National shows, and contains some suggestions concerning lines along which automobile engineers will have to work in the future. Particular stress is laid upon the untried possibilities of the heavy oil engine for automobile work.

Mr. Cornell's paper deals with a quite different subject, being a dissertation upon how best the service department of a factory can anticipate troubles and assist the car owner by a proper system which will insure that the troubles be the minimum, and the attention of service men throughout is asked for.

Auto Shipping Breaks All Records

New York City, Feb. 7—Although affected by the famine in freight cars, the automobile industry in January broke all records for the shipment of automobiles, the official figures supplied by the Traffic Department of the National Automobile Chamber of Commerce, showing 18,054 carloads for last month, as against 8369 carloads in January, 1915, an increase of 115 per cent.

This unusual increase during the winter months is looked upon as one of the most favorable signs of a big spring trade. Moreover, the dealers say that with convertible tops and the constant need of the service which automobiles supply, the marketing of motor cars is now conducted on almost as heavy a scale in winter as in summer.

Chalmers Sells Its Boston Branch

Boston, Mass., Feb. 5—One of the biggest motor transactions in New England was completed this week when the Chalmers Motor Co. of Massachusetts was purchased by O. L. Halsey. The latter had been handling Packard cars at Kansas City for six years, but as he was formerly a Bostonian he wanted to return to the Hub. So he sold out there. He is a brother-in-law of Alvan T. Fuller, who has the Packard at Boston, Portland, Providence and Manchester. Harry Pyke, manager of the Chalmers branch, has gone to Detroit to confer with the factory officials about a position. F. E. Sumner, who was wholesale manager for the Saxon Motor Co., has joined the sales force of the new company, and F. P. Allen, retains his place as manager of the organization, a position he held with the Chalmers branch.

Alliance Motor Elects Officers

Alliance, Ohio, Feb. 7—The annual meeting of the stockholders of the Alliance Motor Car Co. resulted in the election of C. C. Mummert, president; C. G. Kline, vice-president; S. L. Geiger, secretary; J. O. Ellis, treasurer and O. R. Mummert, general manager.

Legalizes Sunday Work in Bay State

Boston, Mass., Feb. 5—The Massachusetts Legislature this week passed the bill to allow motor dealers and garage men to sell supplies like oil, gasoline, tires, etc., and to do necessary repair work on Sundays. Under the law as it stood it was illegal to make any repairs or sales on Sundays, and a Springfield judge convicted a garage man for doing it, warning him and others in that city to refuse to sell anything in future.

Cars in Gallery at Boston Show

Boston, Mass., Feb. 5—The problem of how to house all the applicants for space at the Boston Automobile Show is not yet solved, although a partial plan has been worked out. For the first time there will be cars in the balcony this year. A few years ago a couple of dealers exhibited a few cars upstairs, but not very many. This year seven exhibitors have so far been given space there. It is more advantageous than going into another building, for the balcony circles the main hall so that the cars may be seen.

At the present time just 107 exhibitors of passenger cars and trucks have been allotted space, and there are applications on file for at least 40 more. There will be 74 different makes of passenger cars and 33 makes of trucks so that all told more than 400 machines will be on view.

U-W Pull-Out Line Sells for $3.50

New York City, Feb. 7—In a description of the U-W Pull-Out line manufactured by the Upson-Walton Co., Cleveland, Ohio, in The Automobile for Jan. 27, the price was given as $2. This should have been $3.50.

French Import Tractors

Mankato, Minn., Feb. 8—The Mayer Bros. Co. has contracted to deliver in a 5-year period 186 of its light traction engines to a Paris automobile importing firm. The first shipment is being put together and is to leave soon. Announcement was made to the stockholders at their annual meeting Jan. 26.

261,800 Miles Wins Hyatt Contest

Winner Gets $500—Fifteen Other Prizes — Average Mileage 156,814 Per Car

Detroit, Mich., Feb. 4—F. E. Slason, Plainville, Kans., has been awarded the first prize, $500, by the Hyatt Roller Bearing Co. in its mileage contest among car owners to find the one whose automobile has traveled the greatest distance with its original set of Hyatt roller bearings.

The winner had covered 261,800 in a 1909 Buick up to October, 1915, at which time the car was turned over to the judges of the contest.

Besides Mr. Slason, fifteen other contestants have been awarded prizes, and the winning cars covered a total distance of 2,512,435 miles, which is equal to more than 100 times around the world. The average mileage of the sixteen contestants was 156,814 miles or more than six times around the world.

Of the sixteen winning cars, six are Mitchells, four are Fords, two are Buicks, the other four being a Logan, a Maytag, a Hudson and a Flanders. The oldest car was the Logan, which was a 1916 model. One of the Buicks and one of the Fords were of the year 1908. The winning Buick, three Mitchells, the Flanders and one Ford were 1909 models. Three Mitchells, the Hudson and the Maytag were made in 1910, while two Fords were of the 1911 production.

The regulations of the contest which closed Nov. 1, 1915, provided that any car is eligible provided it had its original equipment of Hyatt roller bearings. The winner was to be the one whose car showed the greatest mileage, and he was to receive $500. The next five prizes were respectively $200, $100, $50, $30 and $20, the next ten to receive $10 each.

THE WINNERS

1. F. E. Slason, Plainville, Kans.—1909-Buick; 261,800 miles.
2. James Lewis, Shelton, Conn.—1909-Mitchell; 218,734 miles.
3. J. W. Norman, Paint Rock, Tex.—1909-Mitchell; 183,837 miles.
4. Sam Deck, Darlington, Ind.—1910-Mitchell; 175,875 miles.
5. J. D. Albright, Bowie, Tex.—1911-Ford; 172,683 miles.
6. Earl G. Druding, Ellsworth, Wis.—1909-Ford; 171,418 miles.
7. S. T. & E. R. R., Stockton, Cal.—1909-Mitchell; 160,100 miles.
8. Jacob Stark, Chicago, Ill.—1906-Logan; 148,150 miles.
9. J. J. Moore, Philadelphia, Pa.—1911-Ford; 147,751 miles.
10. John Fraser, Jr., Milwaukee, Wis.—1908-Buick; 139,523 miles.
11. Geo. R. Mason, Des Moines, Ia.—1910-Maytag; 135,000 miles.
12. J. M. Bertolet, M. D., Reading, Pa.—1910-Mitchell; 127,681 miles.
13. Jas. W. Hines, Minneapolis, Minn.—1910-Hudson; 120,256 miles.
14. Linus Kiene — 1910-Mitchell; 120,000 miles.
15. L. N. Burnett, Dallas, Tex.—1909-Flanders; 116,557 miles.
16. F. I. Wiltse, Oneonta, N. Y.—1908-Ford; 113,061 miles.

Carter Carbureter Forms Sales Dept.

H. C. Weed to Be Vice-President of Carter Co.—Will Direct Sales

NEW YORK CITY, Feb. 7—The Carter Carbureter Co. of St. Louis, Mo., has cancelled the selling arrangements which it has had with the H. W. Johns-Manville Co. of New York for two years past and has arranged to market its products this year through its own sales department.

The H. W. Johns-Manville Co. will continue to sell Carter carbureters and Carter gravity tanks, but will no longer handle the sale of these commodities to automobile manufacturers.

H. C. Weed, general manager of the carbureter department of the H. W. Johns-Manville Co. will continue to direct the sales policy of the Carter company, in the capacity of vice-president and general manager with offices at the factory in St. Louis.

The company will make a specialty of service, with factory experts located in every large city in the country under the direct supervision of the service department at the factory. Sales to the trade will be handled entirely through jobbers and general distributors, the policy of the company being to absolutely restrict the sale of its products to the jobbing trade. R. V. Wright, formerly connected with the H. W. Johns-Manville Co. has been made eastern district sales manager, with headquarters at Philadelphia. J. K. Dalton, formerly of the Stromberg Motor Devices Co., will have charge of the Middle West territory, with headquarters at Indianapolis. G. M. Bicknell, assistant engineer of the company, will have permanent residence at Detroit, and will take care of Carter interests there.

Bossert to Enlarge

UTICA, N. Y., Feb. 5—The Bossert Co., manufacturer of automobile pressed steel metal parts, has arranged for the construction of an additional two-story, 180 by 58-ft., factory building. Business in 1915 was better than in any previous year. Orders now on the books are far ahead of the record of 1915 and make the extension of the plant a necessity.

Salem Rubber Co. to Make Tires

SALEM, PA., Feb. 7—The Salem Rubber Co., a concern with an authorized capital of $600,000, will shortly start operations in Salem, Lawrence county, in the plant formerly occupied by the American Case & Register Co. The new company will have a working force of 150 men and a daily output of 250 automobile tires. A. E. Gordon, of New Castle, will be the general manager of the new plant. C. E. Meyer, of Pittsburgh, is financially interested in the new plant.

The new concern will manufacture a standard guaranteed tire with "Salem" as its trademark. Mr. Gordon will bring with him to Salem an organization of trained men. The chief financial support for the new enterprise will be secured in New Castle, Canton, Youngstown and Pittsburgh.

Rutherford Succeeds Raymond as Goodrich Sales Manager

NEW YORK CITY, Feb. 7—W. O. Rutherford has succeeded H. E. Raymond as sales manager of the B. F. Goodrich Co., Akron, Ohio. Mr. Raymond, who is second vice-president of the company, will continue actively as vice-president, exercising general supervision over sales and advertising policies. Mr. Rutherford has been connected with that company for seventeen years.

Lakeside Foundry 100% Stock Dividend

DETROIT, MICH., Feb. 7—The stockholders of the Lakeside Foundry Co. will receive a 100 per cent stock dividend to be paid from accumulated surplus. The capital stock of the company will also be increased from $40,000 to $120,000.

Hoffman, Sun Engineer, Resigns

ELKHART, IND., Feb. 5—R. C. Hoffman, engineer and designer for the Sun Motor Car Co., Elkhart, Ind., has resigned to devote his time to developing a semi-Diesel type of tractor motor.

Republic Output 600 Monthly

ALMA, MICH., Feb. 5—More trucks will be made and shipped during February by the Republic Motor Truck Co., according to general manager F. W. Ruggles, than during the first eighteen months the company was in business. The production schedule has been arranged on a basis of at least twenty-five trucks per working day and at least 600 for the month. Materials for an output of more than 800 trucks were on hand at the beginning of the month, it is said.

New Truck Co. for Bay City

BAY CITY, MICH., Feb. 3—A two-ton truck designed by Howard P. Woodworth, formerly with the Republic Motor Truck Co., Alma, Mich., will be made here by a new truck company now being organized. This was decided at a meeting of business men at the Board of Commerce. Ten men agreed to furnish capital and James R. Tanner was appointed to look after all the necessary preliminary work.

Crude Oil Price No Explanation

Secretary Lane Puts Onus on Standard Oil for Gasoline Price Increase

CHICAGO, ILL., Feb. 7—Word has reached Chicago that Secretary of the Interior Lane has reported to the Senate that the Standard Oil Co. is to blame for the existing high price of gasoline. While the secretary admits that the production of gasoline has not kept pace with demand, he says there is no relation between the price charged by the oil companies for gasoline and the price they paid the producers for the crude oil. He further declared that through their system of refineries and pipe lines, and especially because of their powerful financial backing, the Standard Oil companies are able to profit both on a rising and falling crude oil market.

The secretary's report was in response to a resolution passed by the Senate several weeks ago directing him to institute an inquiry. He submitted figures showing that production was 41,600,000 barrels in 1915, and that consumption in 1914 was 25 per cent more than 1913 and in 1915, 35 per cent more than in 1914. Exports of gasoline, he said, increased 500,000 barrels in 1914 over 1913 and 1,500,000 barrels in 1915 over the preceding year. Crude oil cost the oil companies less in 1915 than in 1914, he said. In conclusion, the secretary said that the increase in the price of crude oil between January, 1915, and the present was from $1.45 a barrel on the first date to $2.25 at present, gasoline rising in the meantime from 12 to 31 cents.

Protests are being made against the skyrocketing prices in several States, the latest to be heard coming from Missouri, where every car owner in the State is being urged by the independent oil dealers to use their influence with their Congressmen toward defeating the proposed bill for taxing gasoline.

Cram Goes to Overland

DETROIT, MICH., Feb. 8—J. M. Cram, for fourteen years with the Mitchell-Lewis Co., and who was vice-president and sales manager of the L. P. C. Motor Co., Racine, Wis., has joined the sales department of Willys-Overland.

Overland Makes Shipping Record

TOLEDO, OHIO, Feb. 8—The Willys-Overland Co. on Jan. 31 last established a new shipping record when 722 automobiles were sent out from its plant that day. During January, 1915, the total number of cars that left the factory amounted to 4613, as compared with 12,393 for the same month this year.

A year ago the daily shipments from the Overland factory averaged 150 cars, or less than one-fourth of its present output. The manufacturing facilities have been increased in one year so that it is now possible to build 1000 cars every 24 hr. The present floor space available for manufacturing purposes is 103 acres. This is fourteen times the size of the original plant when taken over by Mr. Willys eight years ago.

—

Sutcliffe Edison Advertising Manager

ORANGE, N. J., Feb. 7—Paul Sutcliffe has been appointed advertising manager of the Edison Storage Battery Co., Orange, N. J. Mr. Sutcliffe got his earlier advertising and selling experience in California. On coming East in 1912 he joined the Edison interests, but resigned at the end of a year to become secretary of the W. S. Hill Advertising Co., Pittsburgh, Pa. He has been in the advertising department of the Edison Storage Battery Co. for the past year.

—

Galion Co. to Make Tractor Plow

GALION, OHIO, Feb. 5—The Motor Driven Implement Co. of Galion, Ohio, was incorporated at Columbus recently, with $50,000 capital. The incorporators are E. P. Rayle, Dr. E. D. Helfrich, B. E. Place, S. A. Wheatcraft and H. L. Bodley. The principal output of the company has been in process of perfection for nearly two years, and is now ready for the market. It is a light draft tractor plow, with the plow built into the tractor, the whole to be built so as to sell at a reasonable price. The plow has been tested in all kinds of soil and under all sorts of conditions and is said to have stood the test in every instance.

—

New Capital for American Tire & Rubber Co.

AKRON, OHIO, Feb. 6—Stockholders and directors of the American Tire & Rubber Co. voted to reorganize the company with capital to be furnished by the Mauger-French Co. of Massillon, an investment brokerage firm. Contracts for the transfer of the stock, share for share, were settled and the deal was practically completed.

The American Tire & Rubber Co. has been completely overhauled during the past few weeks by H. A. Croxton and associates, a firm of engineers, hired by the American Tire & Rubber Co., to place its property on a basis so it could be considered by brokers for reorganization.

—

INDIANAPOLIS, IND., Feb. 4—The Premier Motor Corp. of Del. has announced that $1,710,000 of its total capital of $2,500,000, is to be represented in Indiana.

Great Northwest Wants More Cars

—

100,000 Automobiles Is Estimated Requirement of Farmers in Territory

MINNEAPOLIS, MINN., Feb. 6—More than 100,000 farmers in Minnesota are open to buy automobiles. Of the entire registration in the State on Nov. 1, 1915, more than 54 per cent are now owned by farmers. A study of nineteen towns from which cars are registered shows that the most cars are owned in towns supported chiefly by farming or dairying.

For six seasons the coming census of automobiles has been awaited with interest, each season by manufacturers and distributors as a basis for estimate of future sales. This annual digest has been issued for 1915 by the *Farmer*, St. Paul. It places the total registration on going to press at 93,111.

Of the total, when the figures were made, cars registered from Minneapolis, St. Paul and Duluth were altogether 20,541, based on a combined population of 722,871, or thirty-five to the car. Outside these big cities the estimated population of the towns is 640,177, and the registration of cars in the State outside the tri-cities is 64,852. On the basis of thirty-five to the car the actual town ownership of cars is 18,290, leaving 46,562 in the hands of farmers.

In the State there are 155,000 farms with an average wealth of more than $9,000. With the expectation that absence of cars on farms will soon be a rarity, the opportunity to sell automobiles is more than 100,000. Sales increased, according to the table, 33 per cent in 1915.

A number of other details concerning the Northwest territory are given on pages 267, 268 and 269. The tables below, perhaps speak more loudly still.

—

Firestone Rim Business Expands

AKRON, OHIO, Feb. 7—The rim factory of the Firestone Tire & Rubber Co. now occupies more floor space than the whole company did in 1910, according to figures just given out, on expansion of the business at the plant.

The demand for rims for the coming season will be for nearly 1,000,000, and this means a large addition to the present rim plant, the company says. The tire plant has been increased to give a daily output of 12,500 tires a day this year instead of 7500, last year's output. The biggest business in the history of the company is anticipated in 1916.

—

Firestone Heads Rubber Club

NEW YORK CITY, Feb. 3—The Rubber Club of America has elected the following officers: President, H. S. Firestone, Firestone Tire & Rubber Co.; first vice-president, Van H. Cartmell, Kelly-Springfield Tire Co.; second vice-president, H. L. Hotchkiss, United States Rubber Co.; and secretary, H. S. Vorhis.

Vanderbilt Cup Not for Speedway

Refusal to Grant Race to Corona May Reduce New York's Chances

CHICAGO, Feb. 7—Neither the grand prize nor the Vanderbilt cup will be hung up for speedway competition. This is the announcement brought west from New York by G. R. Bentel, manager of the Los Angeles speedway and representative of the Corona Road Racing Assn., who traveled across the continent in hopes of securing the grand prize for the Corona contest, which has been classified as a boulevard or semi-speedway race by the contest board of the A. A. A.

As a consequence, Bentel's long trip was futile as the Motor Cups Holdings Co., which controls both the grand prize and the Vanderbilt cup, refused to grant Corona's request for a grand prize race sanction. The ruling in regard to the historic trophies may alter plans of the New York speedway directors to hold the Vanderbilt cup classic on the Sheepshead Bay course this season.

Corona will run a grand prize race, however, which will be known as the Corona grand prize. In addition to the $12,000 in prize money that has been voted, the Flagler trophy will go to the winner. The contest will be a free-for-all and the distance the same as in 1914, 301 miles. The purse will be split as follows: First, $5,000; second, $3,000; third, $2,000; fourth, $1,000; fifth, $700 and sixth, $300.

Upon his arrival in Chicago yesterday, Bentel received a telegram from Corona acquainting him of the fact that the date of the Corona race had been changed from March 17 to April 8 so that the Corona event will not conflict with the series of meets to be held on the Los Angeles speedway, all of which will be run prior to April 1. The Los Angeles promoters already have received a sanction for a February 22 race and have reserved two additional dates in March. Each of the three events probably will be 100 miles in distance and for $5,000 in purses.

Indianapolis Seat Prices Lowered

INDIANAPOLIS, IND., Feb. 7—A general reduction in admission and seat prices has been made for the coming Memorial 500-mile race on the Indianapolis Speedway on May 30. This year the admission prices have been changed. Instead of the general admission being $2 at every entrance, this price will prevail only at the main gate. Entrance fee at the eastern entrance has been cut to $1. Prices for seats after one is in the grounds have been lowered. The list follows: Box seats in the paddock stand and Stand E formerly sold for $7 and $10. This year the prices for the same seats are $5 and $7. Box seats in Grand Stands A and B remain the same, $7 and $10. Reserved individual seats in these stands are $2.50, the same as last year. Reserved seats in Grand Stand C sold for $2 last year. This year they will be priced at $1. All other seats will call for the expenditure of $1.

Maintenance of Resale Prices Favorable to National Chamber Directors

WASHINGTON, D. C., Feb. 8—The board of directors of the Chamber of Commerce of the United States have voted that the report of a special committee of the National Chamber on the maintenance of resale prices shall be submitted to referendum. The committee had reported to the board that it was not able to present a unanimous report to the board.

A majority recommendation favoring legislation permitting price maintenance was signed by seven of the ten members, two of them, however, modifying their assent by the filing of a supplementary report. With the majority report came the comment that a National Chamber committee had rendered a report last February favorable to the principles of price maintenance and the majority members saw no reason in any way to modify the conclusions arrived at and given to the Chamber at that time.

"But on the contrary," the comment continues, "after additional exhaustive investigation by consulting a large number of organizations, composed of many thousands of members in all branches of trade and industry, as well as many individual producers, distributors and consumers, and after having collected evidence from a great many sources, we repeat the language of the committee's previous resolutions of February, 1915, as our report and conclusions, viz.:

" 'Your committee is convinced that legislation permitting the maintenance of resale prices, under proper restrictions on identified merchandise, for voluntary purchase, made and sold under competitive conditions, would be to the best interest of the producer, the distributor and of the purchasing public, or consumer.' "

Saxons in Strong Demand

DETROIT, MICH., Feb. 5—During January the Saxon Motor Car Co. reports to have received orders for 6792 cars for immediate shipment, which is more than double the former biggest Saxon month, May, 1915, when 3318 orders were received. Shipments of cars in January was 120 per cent greater than in the first months of 1915.

Many Suggested Laws for Mass.

Fifty Bills Affecting Automobiles to Be Discussed in Next Few Weeks

BOSTON, MASS., Feb. 5—There are about fifty bills affecting motor vehicles in one way or another before the Massachusetts Legislature at present. Hearings began on the first of them last week, and it is expected that before the show opens in March they will have all been heard so that the dealers will not be worried about them. The Committee on Roads and Bridges will hear the greater number of them. This committee last year did its work better than any previous committee that ever handled motor legislation. Senator John Haigis is the Senate chairman and Harry Foster the House chairman. Those who have watched the career of Senator Haigis since he entered the Legislature a few years ago believe that he will some day be Governor, for he has a most intelligent grasp of matters, and he knows how to handle men and problems without friction.

Women Drivers Unrestricted

At the sessions Tuesday the first surprise came when the Safe Roads Assn. withdrew its bill that would prevent women driving cars of more than 30 hp. There were nearly 200 women motorists on hand to oppose it. Hearings were held on bills to increase the penalty for driving cars while drunk so that the prison terms would be longer and the Highway Commission suspensions would be greater. The motorists felt that they were willing to do anything possible to check such drivers, but it was argued that legislation would not accomplish very much.

The suggestion was made by James T. Sullivan of the Bay State A. A. that a conference of the motor bodies be held to try to arrange some plan to eliminate the drunken, reckless driver and one was planned to take place.

There is a measure to make the Highway Commission examine every applicant for a license. Another would make the owner responsible for any damage caused by a chauffeur if the owner were in the car at the time. There are bills requiring the Highway Commission to appoint 500 road monitors; another to have all cars use safety devices on front and rear; one to have all vehicles light lamps half an hour after sunset as motor vehicles are required to do now; a bill to make all transportation companies note the maker's and the motor number of every car they handle to trace stolen machines; others call for bond by owners before being allowed to drive, and also for jitneys; for a State motor corps for the militia; for changing the registration fees; to prevent gasoline and kerosene being carried by the same wagon; to prevent contractors spreading tar over the entire width of the highway; to make the Highway Commission grant hearings before revoking a license; to allow motor cars to be operated on the island of Nantucket; to prevent motor cars being driven faster than street cars in cities and towns; to increase the fees on motor trucks; to establish a motor vehicle commission; to appoint motor patrolmen on the roads; to designate cross walks in cities and towns, etc.

There are other bills that have not yet been printed so that their contents are unknown. The motor representatives have been busy lining up to fight the adverse legislation and it is not expected that there will be any bills enacted that will seriously interfere with the motor industry.

Tractor Co. to Be Ford's Personal Property

DETROIT, MICH., Feb. 6—To-day the stockholders of the Ford Motor Co. assigned and quit-claimed to Henry Ford all their rights and interests in the farm tractor business which the latter promoted last year. It means that this business will be conducted as a personal business of Henry Ford and his son Edsel B. Ford, or rather by the firm Henry Ford & Son, which was formed last year.

It was first announced in THE AUTOMOBILE, May 13, 1915, that the Ford Motor Co. will make farm tractors, and in its issue of June 24, the detailed plans for the tractor business were given, it being stated among other things, that Mr. Ford hoped to employ 20,000 men and expected to build 500,000 tractors a year.

At the plant in Dearborn, Mich., where the first tractors were made, it is said that quite a number of new tractors have recently been completed, but only for further testing and experimental purposes. It will probably be many months before the Ford tractor will be ready for the market. It is being further improved, but full particulars will not be given out now.

Kelsey Wheel Increases Stock 50 per Cent

DETROIT, MICH., Feb. 4—The Kelsey Wheel Co., manufacturer of automobile wheels, rims, hubs, etc., has increased its capital stock from $1,000,000 to $1,500,000. Holders of the $600,000 common stock of the original capital will receive a 50 per cent stock dividend, payable from accumulated surplus. Of the new capital $600,000 will be retained in the treasury. The $137,000 outstanding preferred stock will be retired through purchase.

Registrations Up 53% in Colorado

28,254 Automobiles in 1915 Compared with 18,433 in 1914 —Dealers Used 1000 Cars

DENVER, COL., Feb. 3—Complete returns from the entire State just received and checked over by Secretary of State Ramer show 28,254 motor cars registered in Colorado for 1915, as against 18,433 for 1914. This is an increase of 9821 cars, or 53 per cent. Of this total number, 25,188 were for regular owners and 1001 for dealers, showing an increase of 324 over the number of dealers' licenses issued in 1914. Of the total registration, 8338 belonged to Denver. The total number of drivers' licenses was 3533, a substantial gain over the 2058 for 1914. The license revenue from motor cars, which goes to the State and county road funds, was $107,664.70, a gain of $37,282.70 over the $70,382 received from 1914 fees. A total registration of at least 40,000 is predicted for 1916.

There were 1643 licenses reissued for cars bought during the year by owners who took out their license originally for another car, as compared with 482 for 1914, indicating a heavy increase in new car sales to persons already owning cars.

While a surprising share of this increased showing in registration numbers and revenue is believed to be due to the rigid inspection of licenses adopted by Secretary of State Ramer, the bulk of the showing is clearly due to an immense increase in sales during the last year. This inspection uncovered 2071 cases where owners had either failed to take any license whatever or had registered their cars at wrong horsepower and thus paid a lower fee than the law required; 176 non-registrations and improper registrations under the dealers' class; 917 chauffeurs, demonstrators and other persons driving cars belonging to others without required drivers' license; and 685 cases where owners had bought other cars, often of greater horsepower and requiring a higher fee than the car originally registered, and had merely transferred their tag to the new car without having the license reissued and properly recorded. These cases brought the State $8,280 from the first class, $840 from the second, $917 from the third and $1,731.50 from the reissues brought in by the inspectors, making a total of $11,768.50 in fees dodged in different ways by car owners, dealers and drivers.

In a few cases, these evasions of the law took the bold and rather crude form of homemade license tags, which were detected through duplication of some number issued to another person, and through defects in painting, etc. Several taxicab companies, real estate firms and other concerns having a large number of cars were also caught with dealers' licenses and compelled to take out regular owners' licenses as required by law and to pay whatever additional fees were involved.

Weston-Mott Honors Its President

FLINT, MICH., Feb. 3—In a quiet way officials of the Weston-Mott Co., and of other concerns controlled by the General Motors Co., remembered to-day the twentieth anniversary of the connection of President Charles S. Mott with the first named concern. It was on Feb. 3, 1896, that the Weston-Mott Co. was organized, the interest of the Weston family having been bought out by the members of the Mott family. The business was originally started in 1884 in Jamesville, N. Y., wire wheels being made. In March, 1896, Mr. Mott was elected a director. In 1898 the business was moved into a new plant in Utica, N. Y. In June, 1906, a plant was built in Flint and the company moved there in 1907 and incorporated under the laws of Michigan. While the plant was in Utica, Mr. Mott was superintendent. From the time the new plant was started in Utica, Mr. Mott took an active part in the company, holding such positions as superintendent, general manager, vice-president and later president.

Detroit Steel Products to Enlarge

DETROIT, MICH., Feb. 5.—A large addition which will provide 60,000 sq. ft. more floor space will be erected at once by the Detroit Steel Products Co. At the annual meeting of the directors the following officers were elected: Walter S. Russel, president; Robert S. Drummond, vice-president; J. G. Rumney, secretary-treasurer and general manager. The officers and Leo M. Butzel, M. P. Rumney, and C. H. O. Meyer, form the board of directors.

The second of a series of conventions will begin Feb. 7. Instead of a single convention at which all the representatives of the company throughout the country take part, as in former years, there will be probably half a dozen conventions this year. At each of them there will be ten to twenty men coming from a certain district or section of the country. For instance, at next week's meetings there will be the representatives of the Detroit Steel Products Co., from New York, Boston, Philadelphia and other eastern cities.

KALAMAZOO, MICH., Feb. 2—It is stated that the Light Car Axle Co., Chicago, has leased part of the old Michigan Buggy Co.'s plant here, and will locate here within the next three weeks. About seventy-five men are employed.

Gasoline Continues Upward Trend

—

Census Bureau Makes Report of Petroleum Refining in U. S.—176 Plants

New York City, Feb. 7—Last week the general feeling with regard to the gasoline price situation was that things were rather uncomfortable and there was no relief in sight. To-day gasoline went up another cent to 23 cents, tank-wagon, in New York, and there are rumors of cent-a-week boosts for several weeks. "There is no money in gasoline even at 23 cents," according to one of the refining companies. As usual, Jersey City, across the Hudson, is just a cent behind New York. In Philadelphia there has been an increase of 2 cents, making the price 23 cents at the wagon; garages are charging from cost up to 26 cents.

In Boston the price, which was 23 cents last week, has gone up a cent to 24, making the retail prices 26 and 27 cents. Last winter gasoline was selling in Boston for 13 cents wholesale; the last increase is the eleventh since then.

In connection with the rising price of gasoline there is particular interest attached to the Census Bureau's summary for the oil refining industry for 1914 as compared with 1909. This report has just been made public and shows a marked increase of production—in some instances an enormous increase.

Production Increased 170 Per Cent

The 176 establishments reporting for 1914 used 191,262,724 barrels of crude petroleum, as compared with 120,775,439 barrels in 1909, the increase being 70,487,285 barrels, or 58.4 per cent. The cost of the crude petroleum, as reported for 1914, was $249,727,856, an increase of $97,420,816, or 64 per cent, over 1909.

The production of naphthas and lighter products, chiefly gasoline, increased from 10,806,550 barrels in 1909 to 29,200,764 barrels in 1914, or by 170.2 per cent, while the value increased from $39,771,959 to $121,919,307, or by 206.5 per cent.

The statement shows the production of casing-head gasoline in 1914 and includes a summary of the production of crude petroleum by fields in that year as reported by the United States Geological Survey.

The gasoline product of the petroleum refineries does not include casing-head gasoline condensed from natural gas at the gas wells. The total gasoline production, including casing-head gasoline, was 24,711,565 barrels of 50 gal., or 1,235,578,250 gal.

The production of lubricating oils here reported does not include that of establishments engaged in the compounding or blending of petroleum oils, but only the output of petroleum refineries.

Of the 176 refineries in 1914, 48 were in Pennsylvania, 38 in California, 23 in Oklahoma, 13 in Kansas, 9 in Texas, 9 in Illinois, 8 in New Jersey, 7 in Ohio, 6 in New York, 4 in Colorado, 3 in Maryland, 3 in West Virginia, 2 in Wyoming, and 1 each in Indiana, Louisiana and Missouri.

Velie Will Not Change Bodies

Moline, Ill., Feb. 4—The Velie Motor Car Co. has circularized its dealers to the effect that there seems to be some misunderstanding regarding the situation pertaining to model 15 cars. Actually the model 15s coming through the factory at this time are equipped with the same style bodies as have been used in the past. It is expected to furnish a different body for this chassis, but raw material deliveries are so uncertain that it is hardly possible to supply the new bodies before July 1 or thereabouts.

—

Aluminum Shortage Halts Plant

Manitowoc, Wis., Feb. 7—The first important instance of the effect of the rapidly diminishing supply of aluminum was the necessity encountered by the Manitowoc (Wis.) foundry of the Aluminum Castings Co. of closing down t
plant for several days to await the a
rival of new stocks of raw material. T
Manitowoc foundry, like all divisions
the Aluminum Castings Co., has be
working at full speed for several mont
to fill orders, principally for motor ca
ings and parts. The supply of raw
terial has gradually been diminishing a
the available supply advancing shar
in price. The company is assured
ample stocks for its requirements,
has met with some difficulty in gett
prompt deliveries. The delay caused
the temporary cessation of work has b
made up and deliveries of castings
going forward according to schedule.

Chevrolet Output To Be Doubled

Production To Be Stepped Up Monthly Until Plants Turn Out 460 Cars Daily

DETROIT, MICH., Feb. 9—President W. C. Durant has announced that within the next six months the daily output of the Chevrolet Motor Co., Flint, Mich., is to be doubled. It is at the rate of 230 cars a day now and is to be stepped up monthly until the plants are producing 460 daily in August. It is further stated that a new axle plant will be started here at once, while the work on the new assembling plant, an enlargement of the Mason motor plant and the new assembling plant in Oakland, Cal., also soon will be under way.

The assembling of the Chevrolet cars will be gradually concentrated at the assembling plants in New York City, Tarrytown, N. Y., St. Louis, Oakland, and Oshawa, Ont. All motors, axles and most of the parts needed will be made at the parent plant in Flint. In order to be able to get more workingmen the Chevrolet Co. will also put up about 100 homes.

Ascot Park Race March 5

NEW YORK, Feb. 9—The racing season will probably commence with the George Washington Sweepstakes, a 100-mile free-for-all on the Ascot Park Speedway in Los Angeles. A series of sprint races will be held at Ascot on March 5, and a 200-mile free-for-all on March 19. Prizes approximating $18,000 have been hung up for the three Ascot meets.

The drivers, while in the West, will be able to compete in the Corona Grand Prize, which will be held over the 2.7-mile circular boulevard on April 8. The Corona classic is for a purse of $12,000 and the distance is 301 miles.

George R. Bentel, well known in Pacific Coast racing circles, and Frank Lowry, who has been named starter of the four western races, are now in New York arranging details with the American Automobile Association.

Splitdorf Net Profits for 1915 Are $745,107.55

NEWARK, N. J., Feb. 5—The Splitdorf Electrical Co., this city, reports net profits for 1915 of $745,107.55, or a little over 16 per cent on its capital stock of $4,393,000. The assets amounted to $6,451,362.59, and the liabilities to $5,317,333.20, leaving a net profit of $1,134,029.39 to Dec. 31, 1915. The net profit to Dec. 31, 1914 was $388,921.84.

The company received $52,500 in dividends from its subsidiaries, which report earnings totaling $131,597.97, beside the dividends paid and excluding the operations of the Sumter Works, Sumter, S. C., belonging to the Apple Electric Co.

Locomobile Wins Patent Suit

PHILADELPHIA, PA., Feb. 5—Judge Buffington in the Circuit Court of Appeals sitting in this city reversed the decision of the lower court in the case of the Locomobile Company of America vs. Joseph W. Parkin, deciding the case in favor of the Locomobile Company. The case was decided in the lower court in favor of Parkin because of the alleged infringement of certain claims in a patent for a carbureter manufactured by Parkin. The decree was reversed on the grounds that no invention was involved in the patent and the cause was remanded with instructions to dismiss the bill.

Chalmers to Have New Branch

DALLAS. TEX., Feb. 6—Announcement was made in Dallas to-day that the Chalmers Motor Car Company of Detroit, Mich., will in the very near future establish a big branch house in Dallas. The company will also establish a warehouse in which will be kept the various materials: these will be sent to the various representatives in Texas. High officials of the company are expected in Dallas within a few days when a more detailed announcement will be made. This means a big addition to Dallas' Automobile Row, it is said.

Studebaker Plant in Dallas

DALLAS, TEX., Feb. 4—Contract has been awarded by Clarence Linz and M. B. Shannon of Dallas for the erection of a big brick building in Dallas to be occupied by the Studebaker company. This automobile concern, it is said, plans to establish a plant in this city that will cost upward of $150,000. The plant will be located on South Harwood Street and Santa Fe Avenue. The total floor space will be 128,000 sq. ft. It will be the largest assembling plant in the State, it is said, employing several hundred men.

Syndicate to Market $2,000,000 Peerless Truck Bonds

NEW YORK CITY, Feb. 8—About $2,000,000 in Peerless Truck & Motor Corp. 6 per cent convertible gold bonds are to be marketed by a syndicate, composed of Hodenpyl Hardy & Co., this city.

The notes are dated Nov. 10 and mature Nov. 10, 1925. They are convertible at par on and after Nov. 10, 1916, at the option of the holder into common stock, par value $50, of the corporation. They are part of a total outstanding issue of $5,000,000.

Texas Obtains Injunction

Automobile Manufacturer May Not Limit Territory of Dealer Is Court Ruling

DALLAS, TEX., Feb. 2—Indications are that the State of Texas has considerable evidence in its alleged anti-trust suits against the Olds Motor Works and Turner and Davis and Cadillac Motor Car Co., Houston Motor Car Co. and the Munger Automobile Co. of Dallas, as injunctions were granted to-day, Feb. 2, in the district court at Austin. Defendants must also pay the court costs. This means that an automobile concern has not the right to restrict its agents to the sale of cars in a specified district in Texas. The suits were filed two weeks ago through the attorney general's department. No penalties were asked. The State got all it asked for.

Whitaker an Automobile Patent Expert

WASHINGTON, D. C., Feb. 8—During his connection of several years with the United States Patent Office as assistant examiner, N. T. Whitaker examined hundreds of applications for patents for automobile structures, particularly applications on internal combustion engines. He was connected with the division of the patent office where patents on automobile inventions are classified and examined. He has given special study to all inventions pertaining to every form of the automobile industry. Since leaving the patent office, about a month ago, Mr. Whitaker has opened an office in Washington and is making a specialty of patent work.

$1,500,000 in Briscoe 7 Per Cent Cumulative Pref. Offered

DETROIT, MICH., Feb. 8—Andrews & Co. of this city, Cleveland and Chicago, is offering for subscription $1,500,000 7 per cent cumulative preferred stock of the Briscoe Motor Corp. The shares are offered at $105 with a bonus of 20 per cent in common stock. The capital stock of the corporation is $1,500,000 preferred stock and $4,000,000 common stock.

Tobin New Globe Tire President

TRENTON, N. J., Feb. 4—Horace B. Tobin was elected president of the Globe Rubber Tire Mfg. Co., this city, at the annual meeting of the company at Wilmington, Del., Feb. 1, succeeding W. H. Linburg. The other officers were reelected as follows: Vice-presidents, J. S. Broughton, H. L. Joyce; treasurer, H. B. James, and secretary and assistant treasurer, J. P. Hall.

Four More Tire Prices Raised

Kelly-Springfield Lowers Quotations 10 Per Cent—Swinehart Still Unchanged

New York City, Feb. 7—Kelly-Springfield tire prices have been reduced 10 per cent on the popular sizes, making the present list about 15 per cent higher than the old prices in effect before announcement of its rise on Jan. 1. The 30 by 3 size, plain tread, is now listed at $15.20 as compared with $16.35; 34 by 4 is $29.65, the former price being $32.95; and the 36 by 4 is now $31.50 as against $35, formerly. On the non-skid types, the 30 by 3 is $18.10, the 34 by 4 is $36.25 and the 36 by 4 is $38.20.

Nassau prices have been raised 10 per cent. Portage tires are also 10 per cent higher. The tubes have been raised 15 per cent. Braender has raised its prices 15 per cent. These prices apply only to the Eastern States, the quotations in the West being higher on account of freight rates. Combination prices have risen 10 per cent.

Swinehart is one of the few companies which still adheres to its old prices. It is stated that no changes in the near future are contemplated.

The following list of prices gives the present quotations on several of the popular-sized tires whose prices have been revised:

	Plain Tread		Non-Skid	
	New Price	Old Price	New Price	Old Price
PORTAGE				
30 x 3½..	$14.10	$12.80	$16.15	$14.70
34 x 4 ..	23.60	21.45	27.15	24.70
37 x 5 ..	38.85	35.30	44.65	40.60
BRAENDER

34 x 4 ..	29.65	32.95	.....	.....
36 x 4 ..	31.50	35.00	.....	.....
COMBINATION				
30 x 3 ..	10.85	9.85	12.70	11.55
34 x 4 ..	23.60	21.45	27.10	24.65
36 x 4½..	33.35	30.30	39.20	35.65

V Motors Oust Star Type in French Tests

Paris, Dec. 30—Perfection of the automobile organization has made it possible for the French Military authorities to become more exacting in their tests of aeroplane motors. Until recently motors were subjected to a 10 hr. bench test under full load, no motor being considered unless it had gone through this test without a falter. Under the new regulations, motors must undergo a 50-hr. bench test. This is divided into two stages: 25 hr. at nine-tenths load and 25 hr. at full load. The first motor to go through this test successfully was a De Dion Bouton eight-cylinder water cooled model. De Dion Bouton was the first to commercialize the eight-cylinder motor in France; it has been used on this firm's cars for more than three years, and attention has always been given to the same type of motor for aviation purposes. It was not until the war that the firm took up the aviation eight on a big scale.

There are a number of other new motors waiting to undergo their 50 hr. test. The majority of these are V-types, with either eight or twelve cylinders; a few are six-cylinder verticals. As the 10 hr. bench test under full load was looked upon as a serious undertaking, and was not passed by all competitors at the first attempt, the appearance of each engine for the 50 hr. test is being watched with more than ordinary interest. The fact that it is possible, under war conditions, to impose such a test, is proof that the authorities have developed output to such a degree that they can afford to refuse all but the very best motors. The fact that no more rotating cylinder motors are coming up for test, and that V motors are in a majority over all other type, is also significant as an indication of the trend of design.

Favor Horsepower Tax in D. C.

Washington, D. C., Feb. 5—The district commissioners have made a favorable report on the bill introduced in Congress by Representative Page, of North Carolina, to impose a special tax on automobiles in the District of Columbia, based upon horsepower. The commissioners, however, recommend that the bill be so amended as to provide for the elimination of the personal tax on motor vehicles.

The advisability of providing for a double tax is questioned by the commissioners. They believe that only one tax should be imposed, the amount of that to be determined on the horsepower basis. It is declared the double tax proposed by the bill would be excessive and burdensome. They say, for instance, the owner of a 25-hp. car valued at $500 would, under the terms of the bill, be required to pay annually a license tax of $7.50 and a personal tax of like amount. Because of the limited area in this jurisdiction, whether a car is used either for business or pleasure, it is pointed out, it is practically necessary to have a Maryland tag. This would mean, it is declared, in addition to the $15 paid by the owner of the car under the bill, a further payment of $15 would have to be made for the Maryland license. This amount the commissioners believe excessive and burdensome and therefore the elimination of the personal tax was recommended.

Municipal Cars Need License

Only Fire and Police Department Machines from License and Speed Laws

Milwaukee, Wis., Feb. 8—The question of whether or not public motor vehicles are amenable to the statutes requiring the licensing of such vehicles or the rules of speed, has practically been settled in Wisconsin by an opinion of the attorney general. Marc Catlin, district attorney of Outagamie County, Wis., asked if it is necessary for municipalities to register and obtain licenses for municipally-owned cars, and if such cars could exceed the established speed limits of 15 miles in cities and 25 m.p.h. in the country.

The attorney general states that fire and police departmental vehicles are exempt from both the licensing and speed limit requirements, but cars owned by cities and used for other municipal departments or divisions are not exempt from the State law. The opinion is based on the acknowledged principle of public necessity, which requires excessive speed. Fire and police cars are so distinguished as such that license plates are not needed to identify them.

New York State Registrations Increase 36 Per Cent

New York City, Feb. 3—Automobile registrations in this State increased 36 per cent in 1915 over the preceding year. Chauffeur licenses increased 21 per cent and the amount of money paid by owners increased 24 per cent. With the money from fines included, the total from the operation of motor vehicles to be set apart in 1916 for the maintenance of improved highways will be close to $2,000,000.

All told, motoring credentials were issued to 316,185 persons. Of this number, 231,831 were owners, representing 208,421 passenger cars and 23,411 commercial vehicles; 82,153 chauffeurs were licensed and 2201 dealers received certificates. The fees aggregated $1,913,175. The 1914 credentials totaled 235,602; passenger cars, 151,030; trucks, 17,193; chauffeurs, 66,636; dealers, 1743. The fees amounted to $1,529,852, a big increase over 1913.

Maxwells Cheaper in Canada

Windsor, Ont., Feb. 5—Canadian prices of the Maxwell have been reduced by the Maxwell Motor Co. of Canada, Ltd. The touring car is now listed at $850 instead of $925 and the roadster sells for $830 instead of $900.

Detroit Fights Mich. Auto Law

Validity is Upheld in Test Case in Wayne County Court

DETROIT, MICH., Feb. 8—To-day the Wayne County Circuit Court upheld the new Michigan automobile tax law as being constitutional. The case will, however, be carried to the supreme court by the City of Detroit. Every one of the city's claims and reasons given that the law should be considered invalid was decided adversely by the judges. Should the highest court also uphold the law, it means that $15,000,000 in personal property will be taken from the city's assessment rolls. According to this new law motor vehicles are taxed according to horsepower and weight. The money raised from the tax goes into the State's treasury and no other tax on automobiles is to be levied, which deprives the city of Detroit of a large amount formerly collected. One of the city's aldermen and the city prosecuting attorney filed suit against the Detroit Board of Assessors asking the court why a peremptory mandamus should not be issued by this court against the assessors.

Among the many reasons given why the new auto tax law should be considered invalid are the following: That the law discriminates in favor of manufacturers and dealers; that those in the taxicab business and manufacturers and dealers in other lines of business who own large numbers of motor vehicles are required to pay more taxes or a greater amount than the automobile manufacturer or the dealer in automobiles; that the value of the automobile is not taken into consideration in fixing the tax, for instance a motor vehicle several years old of high power is taxed more than a new automobile of less horsepower, yet of greater value, etc.

Georgia Legislature Sets 30 M.P.H. as Speed Limit

SAVANNAH, GA., Feb. 3—A number of radical changes in the automobile laws were made in the motor vehicle act at the recent special session of the legislature, and motor car drivers will have many new things to learn in order to comply strictly with the law.

The State law has no effect on municipal laws not in conflict, but sets a State speed limit of 30 m.p.h., with due regard to width, grade, traffic and common use of the highway. Ten miles an hour is the limit on curves, bridges, railroad crossings, deep descents, etc.

A provision of the law, applying both to automobiles and motorcycles, and based on laws previously in force in several cities, prohibits the passing of any street car, interurban or other passenger train, while the same is standing still for the purpose of taking on or letting off passengers.

The provisions requiring the driver of a motor vehicle to slow down or stop when signalled by the driver of a horse-drawn vehicle and requiring motor vehicle drivers to slow down and give warning by their horns when approaching horse-drawn vehicles, are included in the act.

Any violation is made a misdemeanor.

Electrics Grow in England

NEW YORK CITY, Feb. 7—According to reports received by the Electric Vehicle Assn., recently from an English engineering firm, Heenan & Froude, Ltd., the use of electrics there has increased greatly in the past year, the number from 150 a year ago to 660 to-day. The use of electrics has been stimulated to a great extent by the war, for due to the numbers of men who have been taken from commercial occupations by the wholesale enlistments, the majority of the truck drivers in England to-day are women. The electric is simpler to operate than the gasoline truck, and therefore better adapted to use with female labor.

Another effect of the war has been to effect almost universal withdrawal of certain classes of gasoline trucks, through commandeering, so that to protect themselves, many firms have adopted electrics, for which the government has no need.

3,000,000 Hayes Wheels for 1916

JACKSON, MICH., Feb. 5—During 1915 there were made at the local plant of the Hayes Wheel Co., a total of 1,723,490 wheels, or more than twice as many as in 1914 and more than five times as many wheels as in 1913. There were on the average 1000 men on the company's payroll during the year, but at times the number of shop workers was close to 1400.

The company expects that its estimate of 3,000,000 wheels for 1916 will be below the actual output when the year ends. The production has been remarkably rapid. In 1909 only 81,416 wheels were made at the plant; in 1910 the total was 145,660; in 1911 it was 299,576; in 1912, 322,599; in 1913, production was 333,523; in 1914 the total was 844,609. The total production during those seven years was thus 3,750,872 wheels, or at the rate of four wheels to an automobile, wheels for 937,718 automobiles.

Besides its main plant here, the Hayes company operates a large plant in Anderson, Ind., and has its hub factory in Albion, Mich. These plants employ several hundred men.

Britain Prevents Driver Shortage

London Omnibus Co. Institutes Army School—Lighting Restrictions Very Severe

LONDON, Jan. 15—No more automobile drivers can now be enlisted direct into the mechanical transport service of the British army. The shortage of drivers for civilian purposes has become so acute that users have protested and pointed out that the essential trade of the nation is likely to be paralyzed if more skilled drivers are taken off their ordinary jobs and put into the army. In consequence of this the army has undertaken to train its own drivers and for this purpose has entered into an agreement with the London General Omnibus Company.

At the main depot of this concern recruits, many of whom have never previously sat behind a steering wheel, are now being initiated into the mysteries of the internal combustion motor and taught to drive in regulation convoy formation. The Omnibus company has all the machinery necessary for this training and ought to be able to turn out efficient men in bigger quantities than is possible by any other group. It is understood that these recently trained men will be used to dilute the ranks of skilled drivers. Thus no formation will be composed entirely of new men, but a certain proportion of old and experienced drivers will be retained in each.

No information is allowed to get out regarding the number of men who are being trained in this way, but it is known that the force is considerable. One result of this scheme will be a certain cash saving. Specially enlisted drivers, thousands of whom were taken on during the first months of the war, were paid at the rate of $1.44 per day; the men who are being trained to drive get 24 cents.

Darkness Almost Absolute

During the last few days drastic anti-lighting regulations have gone into force in the greater part of England. It requires a lawyer's training to understand the details of the order, for it is divided in a complicated manner into schedules and the whole of the country divided into areas, each one of which has its special restrictions. Briefly, no brilliant lights are allowed anywhere in England, and around the coast is a strip varying in width from six to 100 miles, within which automobiles must reduce lights to a mere glimmer. Even at Warwick, Coventry and Leamington, in the heart of England, special regulations are in force against lights on vehicles. In the London district headlights are tabooed and side lamps have to be reduced in intensity until they are absolutely useless to the driver. While automobiles have to reduce their lights, other vehicles which formerly carried no light at all must now display a glimmer at the rear. This applies to bicycles, which must show a white light in front and a red light behind, and also to baby carriages.

Automobile drivers are protesting energetically but uselessly against the new regulations. Wherever possible the simplest plan is not to use an automobile at all after dark, but this is not possible in the case of commercial vehicles, and is only applicable with difficulty to certain professions. Doctors are threatening that they will not respond to night calls if there is not some relaxation in the lighting regulations.

There is no doubt that the British authorities have become scared as the result of the last Zeppelin raids over various parts of the country. Lighting has now been reduced to such a degree that the remedy is undoubtedly worse than the disease. Many towns in the heart of England are darker than French towns within artillery fire of the German lines. The London restrictions regarding automobile lights are much more severe than those in Paris and district, although the French capital is only sixty miles from the German front line trenches.

—

Britain Makes Accessories Contraband

WASHINGTON, D. C., Feb. 5—According to a proclamation of Jan. 27 the British Government has made several changes on its lists of absolute contraband, among them being, in regard to item 26, motor vehicles, etc., "there shall be added after the word 'parts,' the words 'and accessories.'"

Overland Features Securities

—

Common Rises 19 Points—Studebaker Stronger—General Motors Down to 445

NEW YORK CITY, Feb. 8—Automobile securities last week were fairly active with a majority of them subject to large gains and losses. Violent trading in these stocks has subsided during the past few weeks. Willys-Overland during the latter part of last week was active, reaching 220 on Saturday with a 19-point gain. This issue together with a 10½-point gain in Packard common, featured the stock exchange activities in automobile stocks. Studebaker pulled itself out of last week's loss by registering a 4-point gain on its common and 1 point on the preferred. These stocks have been active on account of dividend action taken by the directors of the company this week. Maxwell common and second preferred were strong last week with substantial gains.

General Motors Drops 15 Points

Losses last week ranged from a fraction to 15 points. General Motors, which has been steadily declining during the last few weeks dropped 15 points to 445 with little activity. Chalmers common went down 10 points. Kelly-Springfield common and the new common declined 8 and 2 points, respectively. Incidentally a ruling has been made in regard to the new common stock of Kelly-Springfield by the New York Curb Market Assn. This ruling states that Feb. 8 shall be the date of delivery in settlement of all
standing when, as and if issued
tracts in the new $25 common stoc
that company, without further no

*Par value $10. †A

No material changes in prices in crude rubber occurred last week. This product is, however, more active with a firmer tone. Reports from London state that there is now a more plentiful supply of spot rubber, which is calculated to remove all apprehension among consumers for the near future. Para is now quoting at 75 while Ceylon Pale Crepe is a little higher at 83.

Gasoline in this city went up 1 cent yesterday in price to 23 cents a gallon, wholesale. Jobbers throughout the city are selling gasoline at prices running from 25 to 28 cents.

Copper Rise Affects Carbureters

CHICAGO, ILL., Feb. 5—What the increased metal prices is costing the motor car and accessory business is well indicated by the increased price of copper now selling at 26 cents per pound as compared with 14 cents in June. As a result of this increase the carbureter industry will during the coming calendar year pay approximately $750,000 additional for copper alone. This bill would be much greater were it not that many of the carbureters which were water jacketed last year are made without water jackets this season, the result being considerably less copper used in the casting.

Averaging the copper increase at 10 cents per pound, which is conservative, and calculating on 1,200,000 carbureters being needed for 1916, for cars, motorcycles and motorboats, and allowing an average of 5 lb. per carbureter, the total of 6,000,000 pounds of copper is obtained. This at 10 cents per pound increase gives a total advance of $600,000.

Holland Prohibits Rubber Exportation

THE HAGUE, Jan. 27—The exportation of rubber from Holland is prohibited by royal decree to-day. It is understood that as this measure will cut off exports to Germany, Great Britain will order no further interference with shipments of rubber to Holland. In the past rubber cargoes have been held up until it was proved conclusively that they were not consigned to German agents in Holland.

Russell-Overland Merger Made

Deal Long Talked of Now Complete—New Co. is Willys Overland, Ltd.

MONTREAL, CAN., Feb. 3—T. A. Russell of Toronto was a guest of the Montreal Automobile Trade Association on the occasion of the opening of the automobile show Saturday. Mr. Russell stated in an interview that the amalgamation of the Russell Motor business and the Willys-Overland of Canada has now been completed. A charter has been granted for the new company, to be known as Willys-Overland, Limited, of which John N. Willys is president, and Mr. Russell, vice-president.

The factory at West Toronto is being extended and enlarged with the idea of taking care of exports of Overland cars for the British Empire, as well as the Canadian trade, so as to secure a greater volume of production. The policy of maintaining branches with service stations in each province will be continued. Commencing with Feb. 1 the Russell branch in Montreal will take over the combined Overland and Russell business for the entire province of Quebec. J. R. Marlow will manage the business as formerly.

For the present the branch will remain at 5 Park Avenue and will be known as Willys-Overland, Limited, Montreal branch. A track warehouse has also been secured in the shipping district, and it is intended to keep up factory production during the winter months, sending the cars into storage for early spring shipment. In this way 300 to 400 cars will be accommodated in Montreal.

Chandler Stock on 6 Per Cent Basis

CLEVELAND, OHIO, Feb. 7—The Chandler Motor Car Co., this city, has declared a quarterly dividend, payable April 1 to stockholders of record March 7, of 1½ per cent on the stock, thus placing it on a 6 per cent annual basis. The company has no bonds or preferred stock outstanding, and the directors state that they believe the 6 per cent rate is conservative as earnings before April 1 will be equal to 6 per cent on the stock.

On Feb. 4, the company had a cash balance of $1,593,675, which is equivalent to more than $20 a share on its outstanding stock. Sixty cars are being shipped daily, and the output will be materially increased by March 1.

Convention to Discuss Ohio Laws

AKRON, OHIO, Feb. 6.—Reforms in Ohio's traffic and highway code are to be discussed at the annual convention of the Ohio State Automobile Association, which is to be held at Akron, March 31 and April 1.

It is forecast that another movement will be inaugurated to have a general lighting law enacted in Ohio. Since the last session of the legislature there has been a considerable increase in sentiment for the carrying of lights by all vehicles. A recommendation to this effect has been made by State Highway Commissioner Cowen, and the motor organization, in combination with other associations, will seek to have this enacted into the state code.

Vesta Clutch Proves Good

(Concluded from page 284)

are not slid into mesh; consequently there is no clashing or grinding of the gears.

After reaching a speed of 20 m.p.h., the neutral button was pushed in, which broke all electrical connections in the car. It was then demonstrated that the centrifugal force was sufficient to drive the car, as well as to pick up to any higher speed desired, this being done without the aid of any electric or magnetic connection whatever.

Threading the city's traffic at a time when the homeward-bound motorists and pedestrians and the long lines of street cars offer the severest test of a car's handling qualities, we negotiated the streets, at a snail's pace, stopped and started again in obedience to the policeman's whistle and did it all on high. Also we did it with the smoothness and ease of an electric.

In just what way the Vesta Accumulator Co. will market the new device is not fully determined as yet. Officials express the intention to license the Morrison patents to car builders. In addition it is expected that the Vesta people will be building a car before the middle of summer, which will have the new system as the feature.

Factory Miscellany

Covert Motor Vehicle to Build—A contract for the erection of a four-story building at Lock and Grand Streets, Lockport, N. Y., has been awarded by the Covert Motor Vehicle Works. The building will be of concrete and will be 150 by 150 ft.

Tire Plant for Wakefield—T. E. Dwyer has succeeded in getting the Motor Tire Reconstruction Co. of New York to build a factory at Wakefield, Mass., for its New England branch, work being started on a structure on Broadway so designed that it may be enlarged from time to time.

Goodyear to Build Garage—The Goodyear Tire & Rubber Co., Akron, Ohio, has purchased a large tract on Market Street, opposite its plant, where a large garage is to be erected. Tentative plans call for an expenditure of $50,000 for the garage. The B. F. Goodrich Co. took similar action some time ago, having purchased a site upon which a large garage is being erected.

Celfor Tool to Enlarge—Several thousand dollars are to be spent by the Celfor Tool Co., Buchanan, Mich., on different enlargements of the plant. There will be a new shop building, a new office building, a storehouse, a new boiler plant and a 73-ft. smokestack. It will take about four months to complete the enlargements.

Continental Rubber Co. Formed—L. J. Weadock and C. E. Sprague of Toledo; G. W. Doerzbach, J. J. Daach, J. T. Sloat and Sidney Frohman of Sandusky, have incorporated the Continental Rubber Co., Sandusky, Ohio, with a capital of $500,000, to manufacture automobile tires. The company has made arrangements to take over the now unoccupied plant of the Erie Reduction Co., in the southwestern outskirts of the city.

Briscoe Building—Construction of a new one-story office building, 300 ft. long, will be started shortly by the Briscoe Motor Co., Jackson, Mich. An addition is now being erected to the motor department, also a one-story stock room, between the motor and assembly rooms. Gradually other enlargements will be made and by the end of July it is expected that there will be room to give employment to at least 2000 men.

Battery Plant for Peoria—Frank B. Kamarke, will open a manufacturing plant in Peoria, Ill., for storage batteries. It is claimed that batteries can be constructed as economically in central Illinois, as in the East. The plant will be located on Knoxville Avenue and will be ready for business early in February. Mr. Kamarke was for a number of years connected with the Fashion garage of Peoria and has specialized in batteries.

K. C. Tire Plant Progressing—The work of remodeling the factory building recently leased by the newly-organized Kansas City Tire and Rubber Corp., Kansas City, Mo., has gone ahead so successfully that the announcement has been made that the company will be producing five hundred tires daily within the next month. The company also controls a plant in Chester. It will be continued as a part of the Kansas City company, manufacturing the Chester and Traveler tires. The local plant is being constructed with a capacity of one thousand tires daily, but this output will not be attempted for several months. Five hundred men will be employed here.

The Week in the Industry

Anderson Joins Sun—John Anderson has joined the Sun Motor Car Co., Elkhart, Ind., as assistant factory manager. He formerly occupied a similar position with Chandler Motor Car Co., Cleveland.

Jones Beaver Superintendent—Frank Jones has been engaged by the Beaver Manufacturing Co., Milwaukee, Wis., as factory superintendent, succeeding W. A. Carroll, resigned. Mr. Jones took charge Feb. 4.

Sehl Joins Studebaker—J. P. Sehl, commercial body designer, Pierce-Arrow Motor Car Co., Buffalo, N. Y., has resigned to accept a position in the body designing department of the Studebaker Corp., Detroit.

Corman Makes New Connection—E. W. Corman, who was advertising manager of the Saxon Motor Co., has become sales and advertising manager of the Wetmore-Quinn Co., Detroit distributor for the Saxon and Paige.

Bowman White's Columbia Mgr.—F. P. Bowman, formerly of Chicago, Ill., has succeeded R. D. Lampert of this city as manager for the White Co., Cleveland, Ohio, in Columbia, S. C., handling the State. Mr. Lampert has engaged in business for himself.

Grimes Joins National—C. P. Grimes will on Feb. 15 become assistant in charge of the experimental department of the National Motor Vehicle Co., Indianapolis, Ind. Mr. Grimes has for the past 4½ years been connected with Wheeler & Schebler, Indianapolis, in the capacity of technical engineer.

New Braender Tire Managers—The Braender Rubber & Tire Co., Rutherford, N. J., has opened branches in Chicago, Ill., at 1350-54 South Michigan Avenue, and in Philadelphia at 1327 Race Street. The Chicago branch is under the management of W. J. Heathcock and the Philadelphia branch is under W. L. Porter.

Smith Heads American Malleables Office—The American Malleables Co. has opened offices at 1607 Kresge Building, Detroit, Mich., in charge of P. G. Smith, assistant sales manager of the company. The company has two plants, located at Lancaster, N. Y., and Owosso, Mich., and makes a specialty of nothing but malleable castings for the automobile trade.

Elwood Joins Remy—J. L. Elwood, formerly superintendent of the Eureka Electrical Mfg. Co., North East, Pa., has been appointed director of service for the Remy Electric Co., Anderson, Ind. Mr. Elwood has been engaged in the electrical manufacturing business for quite a number of years, having previously been with the Remy company in the production end of the business.

Motor Men in New Roles

Zeigler Co. Starts Operations—The Zeigler Manufacturing Co., Alexandria, Ind., is just starting operations. It has secured the American Wheel Works plant at Alexandria, Ind., which is well equipped for the manufacture of steel stampings and machine products, suitable for the automobile trade. Sales offices have been opened at 910 Merchants' Bank Building, Indianapolis.

Radford Succeeds Gloetzner—W. H. Radford has been appointed assistant engineer in charge of design by the Chalmers Motor Co., Detroit, Mich. He succeeds A. A. Gloetzner, who recently resigned.

K. M. Wise was appointed assistant engineer in charge of the experimental division. He was formerly with the Studebaker Corp. and the Crucible Steel Co. of America.

New Interests in Cleveland Cole—S. S. Mier and E. J. Arnstine have secured a controlling interest in the Cole-Cleveland Co., Cleveland, Ohio, distributor for Cole cars in sixteen counties in northern Ohio. Mr. Mier has been made president of the company and Mr. Arnstine secretary and treasurer. J. M. Smith, former local manager of the company, will continue with it. There will be no change in the line or in the territory and the policy of the company will be continued as in the past.

Fagersten Jeffery Foreign Rep.—Wallis Fagersten of Rockford, Ill., has accepted a position with the Thomas B. Jeffery Co., Kenosha, Wis., to enter its foreign service as traveling representative. He will spend two months at the Kenosha factory in order to become acquainted with the manufacture of trucks suitable for army service, and will spend most of his time in Russia and France meeting purchasing agents of those governments and supervising deliveries.

Changes in Bearings Co. of America—The following changes have recently been made in the Bearings Co. of America, New York City: J. W. Hertzler, who has been for several years past Western representative of that company, has been appointed assistant manager, and is now located at the factory of the company in Lancaster, Pa. Mr. Hertzler is being succeeded in the Detroit office at 604 Ford Building by W. C. Little, who has represented Brandenburg & Co. and the Buda company in that territory.

Changes Planned in Mid-Continent Tire—Several changes probably will be made soon in the directorate of the Mid-Continent Automobile Tire Co., now operating a plant in Wichita, Kan. R. E. Price of Denver already has retired from the company and his place has been taken by A. O. Rorabaugh of Wichita. Most of the stock is owned in Wichita and it is planned to enlarge the directorate from five to nine and fill it with local business men. The plant will have a capacity of about 400 tires daily.

Albright and Williams Make Changes—W. D. Albright, who for the past two years has been manager for the Portland, Ore., branch of the B. F. Goodrich Co., and C. H. Williams, manager of the Portland branch of the Goodyear Tire & Rubber Co., have both received new appointments. Mr. Albright is now Northwest manager of all lines of the Goodrich company, with supervision over all of Oregon, Wash., northern Idaho, western Montana, British Columbia, Alberta and all of Alaska. Mr. Williams has been named manager of the Goodyear branch in Chicago, and J. A. Leatherman has assumed management of the Portland branch.

Boston Trade Changes—E. A. Francis, formerly assistant manager of the wholesale branch of the Saxon Motor Car Co., Detroit, has been made manager, taking the place of F. S. Sumner, who resigned recently to join the O. L. Halsey Company, Chalmers dealers.

F. C. Stetson has been placed in charge of the new tire department handling Mohawks at the Green & Swett Co. on Boylston Street.

Howard Blossom has been appointed manager of the wholesale department of the Jackson Motor Car Co. of New England, taking the place of A. C. McIntyre.

J. W. Bowman, one of the pioneers in the Hub, has added the Daniels Eight to his Velie line.

Bradford Kinsley has been placed in charge of the commercial department of the Coburn-Draper Co., Maxwell agent.

A. C. White, Jr., has resigned from the New England branch of the White Company and taken on the agency for the Vim line.

New Quarters for N. Y. Chandler—The Brady-Murray Motors Corp., New York City dealer of Chandler cars, has practically completed the removal of its service station and stock room department from the old quarters at 245 West Fifty-fifth Street to the new quarters at 1886 Broadway.

Dallas Items—Special representative Louis Goodlet of the Lewis Spring & Axle Co. was in Dallas recently and practically completed arrangements for the handling of the Hollier Eight.

The Johnson Shock Absorber Co. of Texas has established headquarters at 1305 Young Street, Dallas. A. D. Crum is in charge. The Dallas house will carry a full line of Johnson absorbers.

The A. B. Auto Supply Co. is the latest addition to automobile row in Dallas. C. R. Rodeman, formerly with the Firestone Tire & Rubber Co., is in charge. The company has acquired the business of the Walter Barnes Rubber Co. and will carry a full line of automobile supplies.

The Atlas Tire Co. of Kansas City has established an office in Dallas at 2006 Commerce Street.

New Chase Co. in Chicago—L. P. Rasmussen & Co., 2419-2421 South Park Avenue, Chicago, has taken over the Chase line in the Chicago territory. Heretofore the Chase has been represented in Chicago by the Chase Motor Truck Sales Co., a local company organized by H. T. Bouldon, general sales manager for the Chase Motor Truck Co., Syracuse, N. Y., and was conducted as a factory branch. The new dealer will take over the line at once and the factory salesroom at 2027 South Michigan Avenue will be vacated. L. F. Stevens, who has been acting as Chicago manager, will remain with the Chase organization as division sales manager, with headquarters in Chicago.

Cleveland News Items—The Apperson-Cleveland Co., Cleveland, Ohio, has moved to its new quarters at 2352 Euclid Avenue, where handsome salesrooms and a very complete service station have been prepared.

The Cleveland Automatic Machine Co. has purchased 3500 sq. ft. of land adjoining its present factory at 2269 East Sixty-fifth Street, where an addition will be built.

E. R. Johnstone has taken charge of the service department of the Guarantee Auto Repair Co., and will also be an instructor in the Ohio Automobile School which is owned by this company.

G. A. Guyman, for some years special representative of the G. M. C. truck in Ohio, has become associated with the Packard-Cleveland Co.

C. C. Burneet has taken charge of the used car department of the Hudson-Stuyvesant Motor Co. He was formerly sales manager of the used car department of the Cadillac Motor Co.

Baltimore Trade News—The Ford Motor Car Accessory Co., 1411 North Charles Street, Baltimore, Md., is the latest accessory house to enter the local field. I. R. Rollins is manager, and besides conducting the accessory factory the new concern will buy and sell used Ford cars. A repair department will be conducted with free service for their customers, and special prices will be made to new customers. The firm has also secured the agency of the Boston starter for the State of Maryland.

The Motor Car Co., Maryland and Mt. Royal Avenues, Baltimore, Md., distributor of the Overland and Willys-Knight, has found it necessary to acquire additional space and has leased a large building at 1018 Guilford Avenue, this city. The new building will be used exclusively for a repair and service department and contains 18,000 ft. of floor space, with the acquiring of which the Motor Car Co. has one of the largest plants in the South for the handling of business. Cuba, Porto Rico and South American points are supplied by this firm.

The Tire Mart, F. Morrison Boyd, president, Baltimore, Md., has acquired the agency of the Gordon and Ideal tires, manufactured by Gordon Tire & Rubber Co., Canton, Ohio. D. C. Turnbull has joined the Tire Mart sales force.

The Baltimore Oil Engine Co., Baltimore, Md., has been incorporated under the laws of the State of Delaware and will establish a large plant for the manufacture of internal combustion oil engines under the Wygodsky system. A. W. Gieske of Baltimore is president of the company.

The Rutherford Tire Co., Rutherford, N. J., has leased 1950 Linden Avenue, Baltimore, Md., and will establish a branch.

The Rowan Electric Mfg. Co., Baltimore, Md., has been incorporated with $25,000 capital stock by J. S. Rowan, 208 North Holliday Street, B. H. Cram and A. B. McElderry, to manufacture, buy and deal in an automobile starter, valves, etc.

Missouri News Items—The Diamond Motor Car Co., St. Joseph, Mo., has taken over the $15,000 garage and salesroom of the St. Joseph Automobile Co. at Eleventh Street and Frederick Avenue. The St. Joseph company probably will be disbanded, although no definite announcement has been made. It formerly held the agencies for the Hudson, Maxwell and Marmon cars, the Detroit electric, and the G. M. C. truck in northwest Missouri and northeast Kansas. The Hudson agency has been taken over by the Diamond company and the G. M. C. truck by the Holliday Motor Co. Disposition of the other agencies has not been announced.

L. W. Smith, who was manager of the St. Joseph company, will be associated with the new company.

The Farmer Auto Co., agent in this territory for the Ford line, will move into the quarters made vacant by the moving of the Diamond company.

The Franklin Motor Car Co., Kansas City, will move in the near future from its present location, 3340 Main Street, to new quarters recently leased at 1916-18 Grand Avenue. The company's storage and salesrooms will be practically doubled by the change.

Several changes in locations have been made by Kansas City distributing agencies within the past few weeks. The Bush-Morgan Motor Co., agents for the Paige, has leased the three-story building at 1508-10 Grand Avenue, formerly occupied by the Moriarty Motor Co. That company has moved to the new four-story building constructed for it at Twenty-second Street and Grand Avenue.

Hall Bros. & Reeves, agents for the Bull tractor, have taken the building at 1526 McGee Street. The Chalmers company factory branch has taken new sales quarters at 1506-8 McGee Street, and the factory branch of the Chandler company will move to 1830 Grand Avenue. The R-C-H Co. also has taken new quarters, now being located at 1714 Grand Avenue.

Missouri Haynes Co., Kansas City distributor for the Haynes, Marion and Paterson cars in this territory, will move to larger quarters at the southwest corner of Sixteenth Street and Grand Avenue. The Serlis Motor Car Co. also will occupy the same building.

The Serlis Motor Car Co. is the recently organized distributor for the Briscoe there and has maintained temporary quarters at 1702 Grand Avenue. E. L. Reed, formerly sales manager of the Pathfinder agency in Los Angeles, heads the new concern.

Takes Over Chevrolet Retailing in S. Cal.—An important deal in southern California motor circles was completed yesterday when the Chevrolet Sales Co. officially took over the retail distribution of the Chevrolet in that territory. The new company has strong financial backing and is closely allied with the Chevrolet Motor Co. of California which controls the entire Pacific Slope and the Islands of the Pacific.

R. C. Durant, who is identified with the larger corporation, also becomes a prominent figure in the retail corporation. S. F. Seager, who is well known on the Pacific coast on account of his connection with the Oldsmobile company which controls the Coast territory, is another official prominent in the affairs of the new corporation. Both Durant and Seager will continue in the other corporations while the retailing of cars throughout the territory will be entrusted to a corps of trained men.

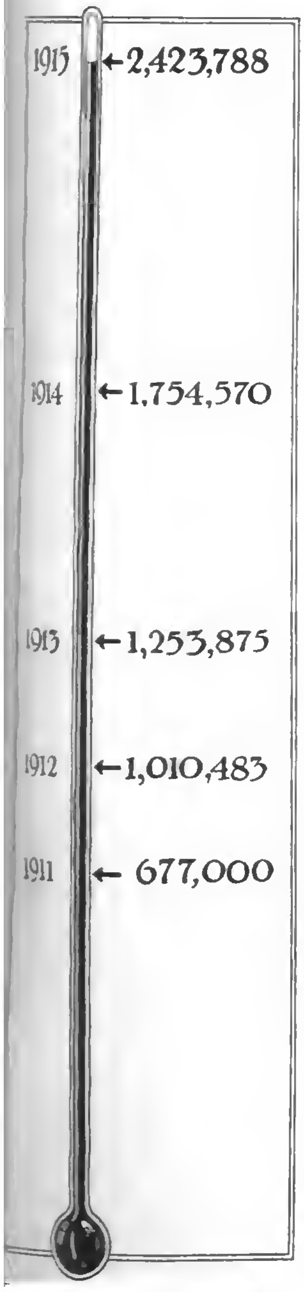
Vol. XXXIV NEW YORK—THURSDAY, FEBRUARY 17, 1916—CHICAGO No. 7

The AUTOMOBILE

United States Has 2,423,788 Cars

1915 Registrations Show Increase of 686,998 Cars and Trucks, or 39.6 Per Cent Over 1914—One Car to 42 People

By Donald McLeod Lay



Illustrating the remarkably [illegible] ratio of increase in automobile and motor truck registrations in the United States [illegible] of the past five years

DURING the calendar year of 1915 there were registered 2,423,788 automobiles and motor trucks in the United States. This total does not include duplicate registrations; at least, all available duplicate registrations have been deducted. The gain in registrations over 1914 was 686,998, which means an increase in the year of 39.6 per cent. Over $4,000,000 was spent in thirty-four States for registration fees alone.

This is a much greater increase than 1914 showed over 1913, when the added registrations for the year totaled 482,915 vehicles. In a word, 1915 showed a 44 per cent greater registration than 1914. Registrations Dec. 31, 1914, were 1,736,790.

Reverting to the grand total of 2,423,788 motor vehicles registered up to Dec. 31, 1915. Taking the latest census department estimate our Government places the population of the United States at 101,208,315 as of Dec. 31, 1915. Taking these two totals as official we have one machine for every forty-two persons in the country.

Considering the gain of 686,998 automobiles and trucks made during 1915, this figure of increase in registration must not be confused with figures of automobile production or manufacture during the calendar year. A conservative estimate has placed the total number of automobiles manufactured at 892,618, this including over 50,000 motor trucks. The number of vehicles registered during the calendar year is naturally much lower owing to the large number exported, also to a considerable number of old cars that have been scrapped or put to other uses and to many cars manufactured during the last three months, many of which are in storage at dealers' warehouses ready for quick delivery when the buying

Standing of the States in automobile and motor truck registration. All duplicate registrations have been deducted

Distribution of automobiles and motor trucks in the various States, all duplicate registrations being deducted

season opens under the influence of approaching warm weather.

Analyzing the gain of 686,998 registered vehicles during the year, many will be surprised to know that considerably more than half of these registrations were recorded in the last six months. The figures are:

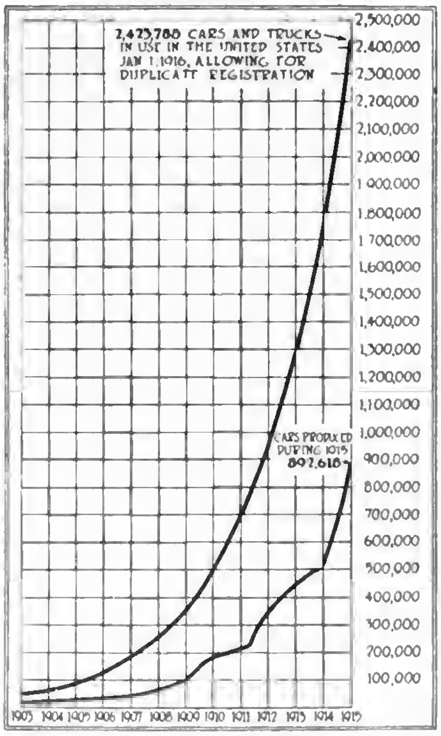
Gain in registrations to July 1............334,113
Gain in last six months....................352,885

Thus it is seen that a practically uniform rate of registration obtains throughout the year, in spite of the heavier selling and re-registration peculiar to spring.

During 1915 several changes occurred in the standing of States having over 100,000 cars and trucks registered. New York continues to lead with 212,844. Illinois keeps second place with 182,290. Ohio, however, has supplanted California in third place with 179,767, as against the Golden State's total of 163,801. Pennsylvania is still fifth with 150,729, followed by Iowa with 139,808; but Massachusetts has yielded seventh place to Michigan, which has jumped up into the 100,000 class with 114,845.

Nine States have between 50,000 and 100,000 cars and trucks, Indiana leading with 96,915, having passed Minnesota, which was one place ahead of it at the end of 1914. Minnesota now has 91,829, while Texas is credited with 90,000. Massachusetts follows with 89,133, and Wisconsin has 81,371; Missouri shows 76,462 registrations and Kansas 74,956; New Jersey has 67,556, and Nebraska registrations total 59,140.

Twenty-five States have registrations varying from 50,000 down to 10,000; Connecticut having 38,950 and the District of Columbia 10,200. In the group with registrations under 10,000 there are eight States, A kansas, Utah, Arizona, Idaho, New Mexico, Delaware, Wy ming, and Nevada. Since registration statistics were fi available the last three States have held this order, th gains being in practically the same proportion each ye Nevada has the fewest cars of any State in the Union, total registration for 1915 being 2177, a gain of 690 o 1914, which is not a bad showing since its population Jan. 1, 1916, according to the estimate just issued by census bureau, is only 104,732.



Registration and production of automobiles and motor trucks in the United States since 1902. Note the uniform upward sweep

Although the majority of the Sta were unable to give statistics cover the number of gasoline cars and tru as compared with electric cars trucks in use, it was possible to obt fairly complete statistics regarding registration of non-residents and registrations due to change of ow ship, etc. These reports show a t of 19,134 cars registered in more t one State, while the number of re-re trations is 55,682. The respective ures for the various States have deducted from the total registratio each instance to secure the actual ber of cars and trucks in use.

Eliminating Duplicate Registration

These statistics have been sec from the State registration officia all cases except the District of Co bia, Mississippi and Texas; all dup tion of registration owing to the car being registered in more than State, cars changing ownership an quired to be re-registered on tha count, etc., is deducted. The sourc information of the three sections tioned are given in the footnote a bottom of page 305.

Taking up the gains made by the various States over their respective totals for 1914 and making allowance for duplicate registrations, Ohio shows the largest increase with 58,502, although it is in third place in the list of total registrations. Ohio has one car to every twenty-eight persons, according to the estimate of the United States census bureau of population up to Jan. 1, 1916.

New York is a close second with 56,671, giving the State a total of 112,844, or one car to every forty-eight of its population.

Illinois, which is second to New York in total registration, as shown in the table on page 303, gained 51,150 cars and trucks during the year, having one to each thirty-three persons.

Pennsylvania is next in order with an increase of 43,588, or one to every fifty-six of its population.

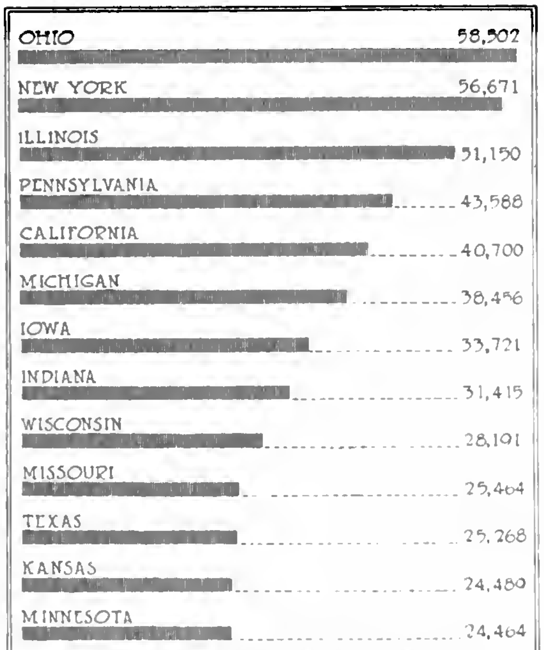
California, which leads Pennsylvania in the total number of vehicles, being in third place, follows the Keystone State in the order of increased registration, having 40,700 to its credit, while its car-to-population ratio is second only to Iowa's, there being one motor vehicle to every eighteen persons.

Michigan ranks sixth, although it follows Iowa in the total number of cars registered, its gain for 1915 being 38,456, while its car-to-population ratio is one to each twenty-six inhabitants.

Iowa follows Michigan in the order of increased registration, showing 33,721, while its car-to-population ratio is the highest of all the States, there being an automobile or truck to every sixteen of its population.

Indiana is the only other State to show an increase of over 30,000 cars, its gain totaling 31,415; the Hoosier State has a motor vehicle to each twenty-nine inhabitants.

A comparison of the tabulations showing total registration



Thirteen States show gains of over 20,000 cars and trucks in 1915

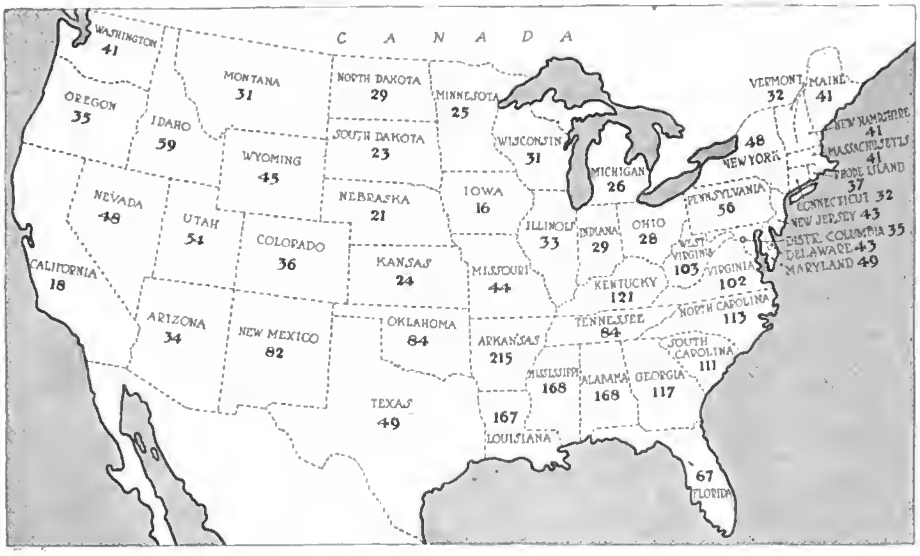
NOTE.—Approximately 3,500 steam cars and 350 steam trucks included in the gasoline vehicle statistics. *Number of cars owned by residents of other States. **Number of cars re-registered owing to change of ownership, etc. ***Not listed separately by registration officials. †Estimated by State registration officials. ††Estimated on basis of population with reference to last registration. §Statistics furnished by Clarion-Ledger, Jackson, Miss. §§Previous estimate considered high by Commissioner. Electric cars and trucks are usually included among gasoline registrations.



Illustrating the population-to-car ratio in the various States. The figures represent the number of people to each automobile or motor truck in the States. The population statistics on which these population-to-car ratios are based are the estimates of the United States census bureau of the population of the various States up to Jan. 1, 1916

and increased registration for 1915 brings out the practically constant ratio of increase in these leading States.

Eight States Gain 10 to 30,000

Eight States show increased registration varying between 10,000 and 30,000. Of these, Wisconsin has the largest gain, registering 28,191 more cars and trucks than in 1914. In this State there is one motor vehicle to every thirty-one persons; Missouri gained 25,464, or more than a number of States ranking higher in the list of total registrations, while its car-to-population ratio is one to forty-four; Texas has an estimated gain of 25,268, there being forty-nine persons to each car and truck in the State; Kansas and Minnesota show the next largest gains, Kansas having 24,489 and Minnesota being credited with 24,464, Kansas having twenty-four persons per car and Minnesota twenty-five; Oklahoma shows 18,255 added registrations, having one car or truck to each eighty-four inhabitants, while the registration officials estimate that there are 5000 cars in the State which their owners have failed to register; Massachusetts and Connecticut show nearly the same gain, Connecticut having 12,732 while its car-to-population ratio is one to thirty-two, and Massachusetts showing 12,301 added registrations, with forty-one persons to each car or truck.

The remaining States show gains varying from Nebraska with 9140 down to Nevada with 690. Thirty-two States show a ratio of not more than fifty persons to each car or truck; seven show between fifty and 100 persons per vehicle, six have between 100 and 150 population per car, and only four run as high as 150 to 215. Arkansas has but one car to each 215 persons, the other three States, Mississippi, Alabama, and Lousiana, having one to 168, 168 and 167 respectively. Probably one reason for this is that the region in which these States lie is largely inhabited by an impecunious negro element, swelling the total population, although unable to purchase automobiles.

245,363 Chauffeurs

Several of the States were able to give the number of chauffeurs registered during 1915, the total being 245,363, or several times the standing army of the United States. It must also be considered that this represents the total in only seventeen States, eleven not requiring chauffeurs to register and twenty-one States being unable to furnish the number. New York, of course, is far in the lead, with 81,266, Pennsylvania being second with 36,747, closely followed by Massachusetts, which has 34,736. Illinois has 22,995 and New Hampshire 17,383, while Ohio is credited with 14,216.

Returns from thirty-four States show receipts from automobile, motor truck and chauffeur registrations of $4,188,755.16. New York leads in fees as well as in registrations, its motorists having paid $1,874,075.50 to the State during 1915. Pennsylvania is second with $1,665,276.50. Iowa has $1,510,745.82 in fees to her credit, while New Jersey automobilists and those visiting the State surrendered $1,062,922.96, and Massachusetts, another great touring State, shows receipts of $1,054,704.50. These are the only States whose fees passed the $1,000,000 mark, although Ohio received $983,789.38 and Illinois $924,905.74.

People are continually pointing to the rapid increase in automobile and motor truck production, demanding what is to become of the enormous motor vehicle production each year. They state that the buying power of the United States has been exhausted or is rapidly nearing its limit so far as motor vehicles are concerned. They warn against continued expansion, holding up the menace of over-production to the industry and prophesying all sorts of disastrous consequences as inevitable if the present rate of progress is sustained. The registration statistics form the foundation for conclusions which indisputably refute all the contentions of these pessimistic prophets. During 1915 the production of automobiles and motor trucks by the manufac-

Dealers, Garages, Supply, Repair and Charging Stations in the United States

turers of the United States reached a total of nearly 900,000 vehicles, a goodly percentage of these being exported to Europe, Asia, South America, in all, eighty countries in different sections of the globe, the number of cars and trucks shipped abroad increasing each month as shown by the government export statistics, the increase for the year being 250 per cent while their estimated value is $100,000,000.

Nearly 2,000,000 Gain Since 1911

The tremendous buying power of the country is well illustrated by the phenomenal increase in the number of automobiles and trucks in use in the United States since 1911. For that year a total of 677,000 was recorded, which, during 1912, jumped to 1,010,483, a gain of 333,483. In 1913 the total was 1,253,875, or 243,392 more than were recorded as being in use during the preceding year. As shown by the 1914 and 1915 statistics mentioned above, the increase in the number of vehicles in use from 1911 to the end of 1915 is 1,746,788, or practically the total number of cars and trucks in use in this country a year ago. In other words, the gain in car and truck registrations during 1915 is almost as large as the total number in use at the end of 1911.

Taken in conjunction with the yearly production statistics, the registrations are specially significant. In 1911 American automobile and truck manufacturers produced 209,957 cars and trucks, their annual output increasing rapidly with each succeeding year. In 1912 a total of 378,261 vehicles left their factories, increasing to 450,000 in 1913, and for 1914 the figure of 515,000 given by the National Automobile Chamber of Commerce was held to be so conservative that it was from 5000 to 15,000 below the actual production total for the year. The Chamber estimated that 30,000 of the number given were commercial vehicles. During 1915 the same authority gives a total production of 892,618 cars and trucks, of which 842,249 were passenger cars and 50,369 were commercial vehicles. Over 200,000 freight carloads of automobiles were shipped during that year.

$691,778,950 in Cars and Trucks

The total retail value of the automobiles and trucks built in the United States in 1915 was given as $691,778,950, of which $565,856,450 represented the passenger cars and $125,992,500 the commercial vehicles.

It was pointed out in THE AUTOMOBILE for Aug. 12 that the statistics for the first six months of 1915 showed that the sale of automobiles to farmers and people living in small communities was rapidly increasing. This tendency was continued throughout the year, and it is significant that such agricultural centers as Illinois, Iowa, Indiana, Minnesota and Wisconsin are well up toward the top of the car registration list. Farmers are coming to realize more and more that the automobile possesses greater potential possibilities for the development and broadening of their lives and business opportunities than any other factor. In fact, it is really more valuable to farmers than to any other class of people, as it brings them more closely into touch with the centers of population where they buy and sell than is possible with any other form of conveyance. In addition to this there is the important phase of the situation presented by the facilitation of social activity in rural districts rendered possible by the automobile. Farm life can no longer be described as unavoidably dull and lonesome as practically every aspect of it has been brightened by the influence of the automobile.

The continued rainy and stormy weather in some sections

Average for U. S.			42.00

of the country during the early part of 1915 had a very bad effect on the standing crops, road conditions and numerous other factors which must always be considered as influences on the automobile market. In view of these conditions the marked increase in registrations in these districts is especially significant as indicating their general prosperity and buying power.

A factor of the 1915 car and truck market was the export business with European belligerents. This demand in addition to the large domestic sales rendered necessary the extension of factory facilities by practically every automobile, motor truck and parts manufacturer in the United States. This activity has already been summarized in THE AUTOMOBILE for Dec. 23.

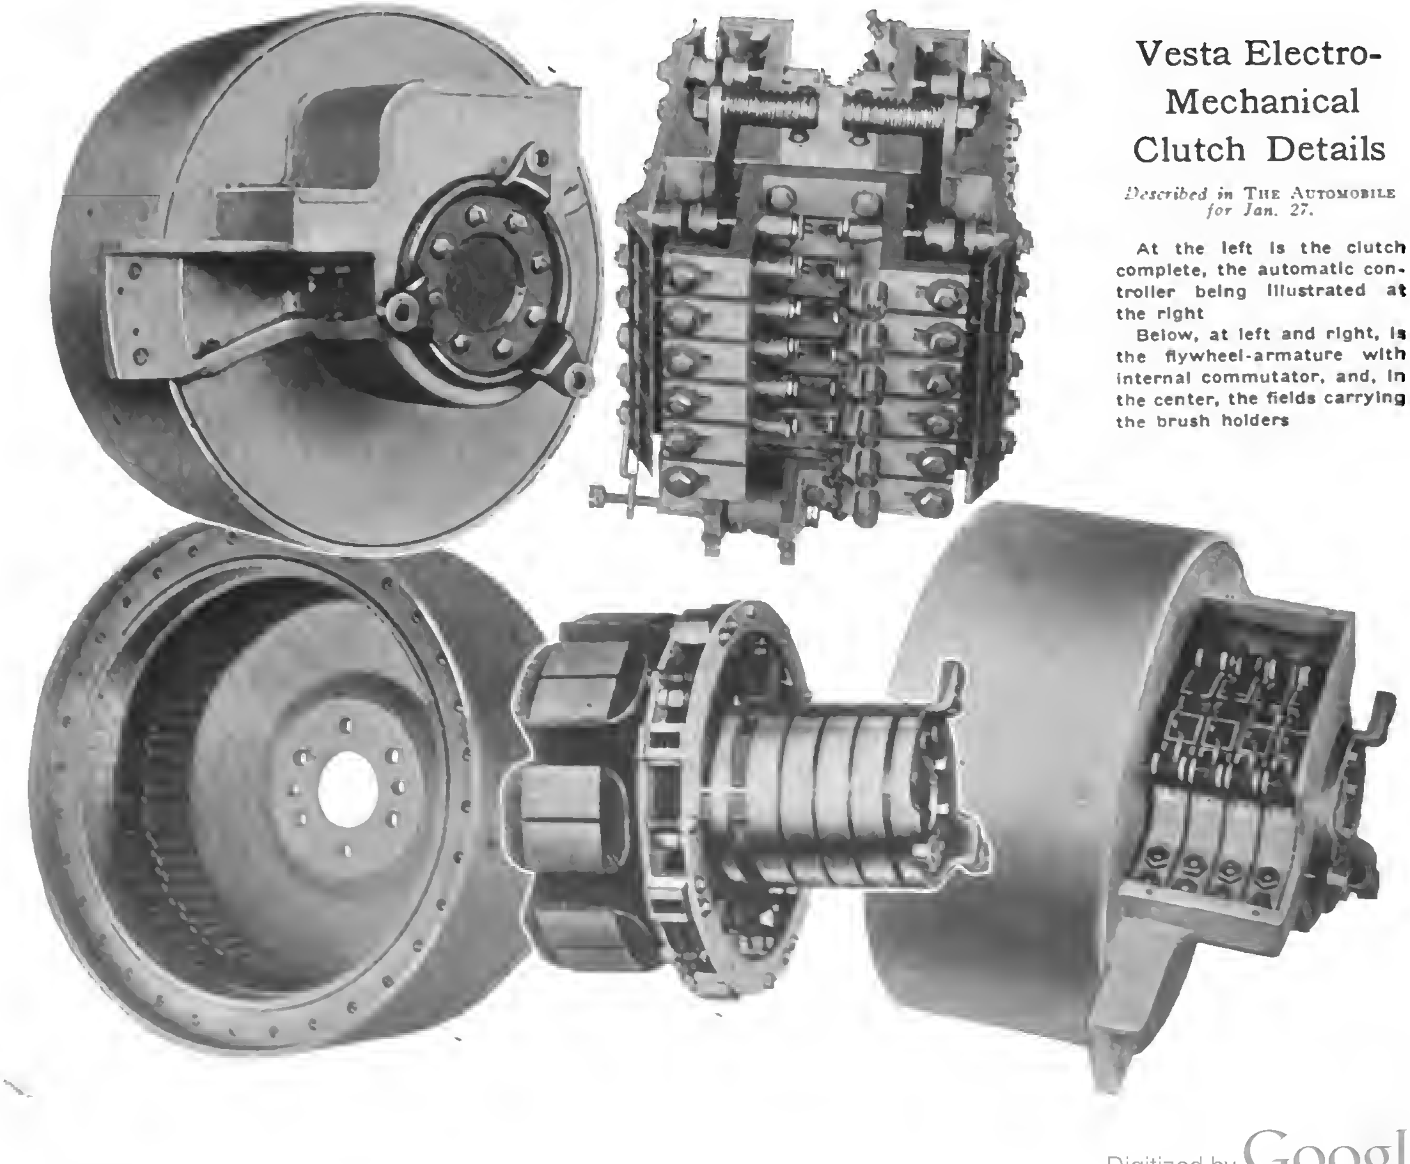
20,458 Dealers in United States

According to statistics compiled by *The Automobile Trade Directory*, there were 20,458 automobile dealers in the United States at the end of 1915, garages numbered 18,560, repair shops 7160, supply dealers 1102 and charging stations 1439. The total is given as 31,793, a number of the dealers keeping garages or repair shops, etc., so that the total does not tally with the sum of dealers, repair shops, supply dealers and charging stations. The distribution of these establishments throughout the various States is shown in the tabulation on page 306. The same authority gives the total number of manufacturers of automobiles, motor trucks and motors as 512. This total does not tally with the 230 manufacturers of automobiles, 267 truck makers and sixty-one motor builders because many of the automobile manufacturers build trucks as well. The distribution by States is given in the table on page 307, twenty-nine States and the District of Columbia being represented.

In the tabulation at the bottom of page 305 are given the total registrations, including non-resident registrations and number of cars re-registered owing to transfer of ownership, etc. In the tabulation on the opening page these duplicate registrations have been deducted, leaving the statistics for each State as accurate as it is possible to make them under the recording system at present in use in most of the States. Very few of the States have registration systems permitting them to give complete information relative to the number of cars of various types, such as gasoline passenger and commercial, electric passenger and commercial, etc. In fact, the majority are able to give but one figure, which is the total number of automobiles and motor trucks in use in the State, irrespective of methods of propulsion.

Nine States Have New Laws

Nine States have new automobile laws passed during 1915, these being California, Delaware, Florida, Michigan, Nebraska, New Jersey, Oklahoma, Tennessee and Washington. Perennial registration still reigns in the District of Columbia and Utah, while Texas has both local and perennial registration. Only one State, South Carolina, now has purely local registration, Louisiana having joined the majority with State registration during 1915. Triennial registration, or registration every three years, is still found in Minnesota. The general tendency in automobile legislation may be characterized as toward sane and reasonable measures, as contrasted with previous years when freak bills were much more numerous.



Vesta Electro-Mechanical Clutch Details

Described in THE AUTOMOBILE *for Jan. 27.*

At the left is the clutch complete, the automatic controller being illustrated at the right

Below, at left and right, is the flywheel-armature with internal commutator, and, in the center, the fields carrying the brush holders

Trend and Possibilities of Automobile Design*

An Analysis of Designs Seen at the Shows—Future of Two Stroke and Crude Oil Motors

By A. Ludlow Clayden and L. V. Spencer

THE effect upon the French trade of dropping their exhibition as an annual affair, in going three years or more without it, was to let French automobile design drop back, allowing England to take the lead. Perhaps it was not an effect, but merely the two things happened simultaneously, but however this may be, there is absolutely no doubt that the quality of French engineering improved a great deal within two years of the resumption of annual shows.

In America we are liable to think that all engineering that matters can be seen in Detroit, that the Detroit engineer has no need to go to New York or to Chicago, because he knows it all beforehand; but *does he?* There are two good reasons for believing that he does not. One is that Detroit, important though it is, is still not absolutely everything in the automobile world, although it forms the larger part; and the second reason, which is far the more important, is that even a Detroit engineer has no opportunity to get a true perspective of progress unless he sees his own car and his competitor's alongside. It is possible to see any number of things one or two at a time and never get a clear view until all of them are seen together. So while it *is* possible to study most of the cars that matter, right here in Detroit, it is impossible properly to appraise them unless they be gathered in groups of hundreds together.

Shows in America

The American show as a spectacle loses greatly on account of the lack of buildings with a single large spread of floor. It is much less impressive at first glance than either the British or French show. Of course, the latter is housed in one of the finest buildings in the whole world, such a building as Chicago and New York ought to possess and no doubt will some day; but it is not fair to blame the building on the exhibition.

Taking, therefore, the stands in detail, the American arrangement is very good indeed. The decoration is much less costly than the uniform schemes used in Paris, and usually the British exhibitor with his individual decoration and equipment spends far more. There is one advantage in the British system, this being that the wealthy manufacturers are able to emphasize their prominence in the industry by using a really fine stand, and the less important firms appear as such. Here the small maker seems to obtain too much prominence. One might sum this up by saying that individual-stand decoration and the division into space sections in accordance with earnings, as used this year, do not seem to be completely effective.

From the merchandising viewpoint the American show leads by an immense distance. It is far easier to obtain information about an exhibit here than in England or France, and though there are plenty of inefficient salesmen to be found on the stands, they are a minority instead of being a 99-per-cent majority. Combine the Parisian grand palace, the individual-stand decorations of London, and use American salesmen, and one would have the ideal show from the spectacular and merchandising viewpoints.

As an engineering display, there is nothing to choose between America and France, but the palm goes to England, *solely for the reason that the Olympia show is the most thoroughly representative.* In London there appear all the British cars, all the French and Italian cars that are of any importance, and quite a number of American cars. At Olympia the cars of all nations are on view.

Leaving all consideration of price on one side, American automobile engineering has reached a high pitch of development as compared with the rest of the world, so in offering criticism it is with the idea that by being dissatisfied with what we have it may be improved still more. A state of perfect contentment with the automobiles of 1916 is greatly to be desired on the part of the user, but it would be most unwise on the part of the engineer. We are not going to be at the end of passenger car chassis development within ten years, nor within fifty.

During the past year we have seen a situation unparalleled in the history of the industry, because we have been trying both to increase the volumetric efficiency of engines while simultaneously trying to cheapen them. This attempt has been successful almost entirely by reason of greatly improved design. Positive figures are lacking, but it is safe to say that never before have so many completely new engines been designed in a single year.

The Ideal Size of Cylinder

It is very tempting to examine the motors of the cars at the 1916 shows and to argue therefrom that the idea of limited individual cylinder capacity has been vindicated. The idea that the eight, the twelve and the six, to say nothing of the four, have each their proper place in the sphere of things, assuming that there is a best individual cylinder size, is well borne out by the shows; but a true critic must not trust his own judgment and must not be tempted to allow appearances to sway his judgment. Thus, trying to eliminate prejudice in favor of a cherished idea, it seems that the cylinder question must wait a year or two before it is settled.

One thing is without doubt, and this is that the much better performance of the average six is due to the coming of the eight and twelve. The six-cylinder engine, as seen on show chassis, is much neater, much more compact and distinctly better finished than was the average six of 1915, and the performance on the road and the speedway of the 1916 sixes shows that this appearance is not misleading. Mr. Howard Coffin said on board the Noronic this last summer that he thought the coming of the V-motor would force American manufacturers to produce some *good* sixes, and certainly they have done it. Are we at the end of development along this line? It is easy to say no and almost equally

---

*Extracts from a paper to be presented at the meeting of the Detroit Section, Society of Automobile Engineers, February 16, 1916.

as easy to say yes; but he would be a bold man that would dare to stake his fortune one way or the other.

It was only when the twelve was evolved that the cylinder question could reach its limit. There is nothing to be gained in theory, in going beyond this number, unless we turn to rotating cylinder engines of the Gnome type, so now at last we have all possible sorts of cylinder arrangement before us, from four to twelve. For the first time the cylinder question can be left to the public to work out for themselves, and how they will do it no man knows. The engineer seeks certain qualities of performance and he knows he can get them by different means with different sorts of engine. It is for the individual to choose his means, to choose what qualities he will sacrifice in order to gain other qualities. It has come to a game of give-and-take, with all the cards on the table.

Importance of Condition

Now, while there is nothing more satisfactory than the small-cylinder four in a little car, it is absolutely essential that it be kept in good trim, or the power falls off woefully, and in the same ratio an eight or twelve with minute cylinders will need to have its valves maintained in proper adjustment, to have every detail kept in proper condition.

Much has been written about accessibility and much more been talked during the past year, but however necessary it may be to maintain, from a sales point of view, that eights and twelves are easy to keep in good tune, an engineer cannot blink the fact that an L-head engine of V-formation is horribly inaccessible as compared with a vertical-cylinder engine of the same standard of engineering. The main factor in keeping the little cylinder at good efficiency is maintenance of proper tappet-adjustment. The average owner of an automobile, whether in this country or any other, is not capable of adjusting the ordinary kind of tappet with a set screw and lock nut. The smaller these parts and the smaller the valves, the more difficult does the adjusting process become. On a vertical engine where the valve stems are quite clear, the average man cannot tackle them, on a V-engine his case is infinitely worse. Thus there is reason to believe that the success of the small eight and of the small twelve is largely bound up with the possibility of improving their ease of adjustment.

In an overhead-valve engine with valve adjustment on the rocker fulcrums it is possible to adjust the tappets while the engine is running, and the job can be done quickly and easily by the least skilled, once the method has been explained, and it can be explained easily in writing without demonstration. There are many pros and cons for the valve-in-head construction, but if so facile an adjustment can be provided for this type of engine, why not for the L-head variety? We have held to the old-fashioned methods too long, so valve mechanism, especially as regards adjustability, may be written down as one of the problems of automobile-engine design that remain to be overcome.

Lubrication Could Be Improved

Another part of engine design that is imperfect is lubrication, though this is being improved by slow degrees. Signs are not wanting that a proper proportioning of the oil supply to the pressures prevailing in the engine at the moment is a growing ideal, and its general adoption cannot fail to bring about a considerable oil-economy together with a decrease in the rapidity of carbonization. In this connection it may be questioned whether the most advantageous feature of the aluminum-alloy piston will not ultimately be found to be the ability to make it long without greatly increased weight. This matter of long or short pistons, of the long piston as a preventive of overlubrication of cylinders, versus the short piston with other means for keeping down the oil, must be thrashed out this year. This year we have got to do our utmost to evolve some standard pistons, for the modern methods for making pistons would be facilitated enormously by the creation of a half dozen standard sizes. The problem is difficult, but it is not nearly as difficult as many others the S. A. E. has tackled successfully.

Troubles of Thermo-Syphon Circulation

Turning to the cooling system of the engine, we see syphonic circulation,—or, more correctly, convection cooling—growing in favor, but study of the cars at the shows discloses the fact that the pump has often been discarded without proper appreciation of the conditions under which a convection system of cooling works. In a system of this sort we have always the hot water at the top, and the cold at the bottom, and if the cylinders are situated at a level with the middle of the radiator they will have approximately the same temperature as the middle of the radiator; in other words, the part of the radiator below the level of the cylinder jackets is useful only as a water tank and has little value as a radiator. With convection cooling a high radiator and a low-placed motor are essentials for success unless a great deal more water is carried than is really necessary. Another much-neglected point is the necessity for providing a good head of water at the top of the radiator. As soon as enough water has evaporated to uncover the outlet pipe from the cylinders at the point where it enters the radiator, circulation theoretically ceases. Practically, it does not cease for some time longer, because the water around the valves boils vigorously and the steam thus formed throws the water into the radiator by a splashing action like a kettle boiling over through the spout. Modern ideas of beauty make it difficult to provide a water container at the top of the radiator that is at least 4 or 5 in. deep, and 4 or 5 in. of water are essential if a convection system is to be really satisfactory.

Aluminum and High Temperature

A review of this kind would be incomplete without some mention of the aluminum engine, but so much has been written concerning it that there is no need for lengthy recapitulation. Its future seems to be entirely bound up with the price of aluminum. Let aluminum come down to under 20 cents a pound, and its cost would be little greater than that of cast iron, when the greater ease of machining is considered. There are a few optimistic spirits who think it is only a matter of finding the correct alloys to be able to use an aluminum cylinder and piston without an iron liner, but whether this be so there seems little doubt that the aluminum cylinder is going to make it easier to keep the small multi-cylinder engine in good order. When dealing with high pressures and temperatures, such as prevail in engines with a large power-size ratio, nine-tenths of the trouble is due to heat. Now, the parts from which we want to remove heat with the greatest possible rapidity are the valves and the pistons. The success of the aluminum piston in racing is explained by the fact that its head keeps cooler than that of an iron or steel piston. The walls of the aluminum piston may be actually hotter, but the better conductivity enables the *maximum* temperature at any part of the engine to be kept within bounds. So with the aluminum cylinder, the temperature of the water should be the same as with iron castings, but the difference in temperature of the parts exposed to greatest heat, which are the valve ports, and the parts best cooled, will be smaller. In other words, the aluminum cylinder ought to allow us to use a high efficiency engine with a smaller liability for trouble.

Aluminum may possibly develop some defects after long use as a cylinder material. We may find that it deteriorates with prolonged heating, but experiments have been made for long enough now to make this doubt a very small matter. Cheap aluminum is all we ask to enable us to save weight and increase efficiency without increasing liability to trouble.

There are plenty of other points about engines outside the number of cylinders they may possess. Foremost in impression after looking at a show is the number of detachable cylinder-heads, and this seems a step forward from two viewpoints. First, as befits the engineer, the theoretical may be mentioned, and this is that it is easier to cool the spark plugs properly when they screw straight into the waterjacket than when they are attached to uncooled valve-caps, and the elimination of valve-caps ought to increase slightly the volumetric efficiency of the engine.

Secondly, as befits the commercially minded, the detachable head is a simply prodigious advantage to the owner who wants to grind his valves or scrape his cylinders and pistons. In nearly every case half this advantage is thrown away by making the detachable head in one piece. To lift a single-piece head off a good-sized six needs some effort, and it is a clumsy thing to handle when it is off; whereas, if it is divided into two portions, either is readily handled. Also, the amateur is none too skilled in making gas-tight joints, and the larger the single gasket, the more likely is he to go wrong.

Having due regard to the fact that the forming of carbon deposit is the chief trouble from which the owner suffers, it seems wise to make a feature of the easiest possible means for opening up the combustion space of the cylinder, and this is a point of design that has hardly been touched. Even where a divided detachable-head is used the number of nuts to be unscrewed is excessive, and there surely ought to be some easier way of securely attaching a loose head-piece than by nuts and studs.

Manifestly a dog piece with a single screw, like a tappet retainer, is not practicable, since it calls for too great a rigidity on the headpiece itself, but there are two unexploited alternatives. Could not the nuts and studs be replaced by cams operated by a small lever, or probably still more simple, could not a system be devised whereby the driving in or out of a few small wedges with a hammer would suffice to secure or to release the head? The day has come when the owner's convenience in this sort of way is more worth studying than any other new thing that offers.

Broad Trends in Motor Design

One thing stands out prominently above all others, and this is that all automobile development has been toward smaller cylinders and higher speeds. To this development there must be a limit, as to all other things, and it is difficult to see when we have reached it and when we have passed it. To-day, taking a very broad average of the whole world, it certainly appears that the 3 to 3.25-in. bore and the 4.5 to 6-in. stroke were the economical limits. That a compression of about 75 lb. gage was a happy mean, that a horsepower peak at about 2000 ft. per minute piston speed was the all-round best thing. Leave every factor alone, and one might venture to say that these things positively are correct, but we cannot tell what will happen to bring in another factor.

For example, during the year the number of cars with overhead valves has decreased, but this may easily be misleading when endeavoring to estimate the trend in valve construction. Those that have gone have mostly been old designs, old types that were not so good as the modern. Simultaneously we see several new overhead designs produced that are infinitely superior to the old types. The latter have not yet had time to make their influence felt; it will take a couple of years more for them to establish themselves or to fade away, and so the trend figures again must be examined with care.

Will Concealed Parts Increase?

A point worthy of consideration and of debate is how much further the inclosure of accessories is going to be carried. Block cast, integral cylinders and crankcase as universal practice in automobile engineering seems a certain development, especially if we get the aluminum cylinder as conventional design. The better cooling now generally provided, again to be assisted by aluminum cylinders, will draw us back again toward the integral exhaust manifold, as it has made conventional the integral intake passage. The bell housing is destined to become universal, unless trends are altogether wrong up to date, and control mechanism of all sorts is being steadily unified into some sort of assembly that is complete in itself. One may ask whether we shall borrow further from the Italian school of automobile engineering, and inclose the electrical apparatus, as is done on the Fergus car, or whether the housing for the steering gears will become integral with the crankcase? There is, however, one detail of the engine that may possibly be separated from the unit of which it is now usually a part, and this is the oil pump. As temperatures in the combustion chamber are increased, the necessity for cooling the lubricant increases. Cold oil is vastly more efficient than hot oil, as has been demonstrated beyond question. In the Stutz racing engine the oil pump is a separate assembly and the whole pump is exposed where it obtains the advantage of the air current.

New Transmissions Important

While interest centers mainly upon the engine, it must not be forgotten that there are other parts of the chassis equally worthy of consideration. That the present form of gearbox and clutch will change but little in the next few years is almost certain; it is as certain as anything can be in so rapidly expanding a branch of engineering; but electric transmission is not to be dismissed with a scornful smile.

To-day the gas-electric system is in the same state of infancy that the internal-combustion engine was in 1900. There are a few enthusiasts who believe in it, and they may be just as correct in their belief as was the similar small band who believed in the motor car sixteen years ago. In 1912 there were many good engineers who thought we had developed the automobile nearly to the limit, and how wrong they were time has shown. The electric transmission enables us to get rid of the need for providing the amount of excess power necessary to give the high-gear performance now considered necessary. It allows the minimum speed of the gasoline motor to be several hundred revolutions per minute higher, so easing the carburetion problem, and it allows higher average gearing to be used with a large engine, or a smaller engine with the same gearing we have to-day.

Faults of Brakes and Steering

However, to leave the visionary and return to the very practical, there are two things in which the average car of 1916 is lacking, and two important things—first, the brakes, and, second, the steering. While engineers of all countries have been devoting their time and study to making the automobile go forward, few of them have given much attention to the equally important matter of keeping it under proper control. The car of 1916 is much faster than the car of 1904, yet it is practically no easier to steer or stop.

In designing brakes, the mathematics of the question ought to be considered, and then should be followed by proper tests of brake-surface materials, of details of shoe design, and so on. A brake ought to act smoothly and quietly, and without more than 20 lb. of pressure on the pedal. It ought to remain in perfect condition for at least 10,000 miles of driving, and when adjustment is needed it ought to be made by turning a single thumb-nut. It is possible to make brakes like this, but it is not easy, because so very little is known about the fundamentals of the subject.

Furthermore, it is fundamentally wrong to put all braking restraint on the rear wheels, and since the theory of front wheel-brakes is not too generally understood, it may be permitted to explain this briefly.

When a brake is applied the car as a whole tries to turn around on the axle; so applying a rear-wheel brake puts on a torque which is resisted by the pressure of the front wheels on the ground, they forming the other end of the lever. If the adhesion of the rear wheels is insufficient, so that one of them locks, that wheel is instantly useless for steering, and if the second locks the whole axle cannot be steered.

With front-wheel brakes the tendency of the application is to lift the whole car, so throwing more weight on the front axle and so pressing the wheels harder against the ground, which reduces the liability to lock the wheel, since the adhesion is increased. But—and here comes the whole difficulty—if front-wheel brakes should be applied with sufficient force to lock the wheels, all steering power is lost, and the fact that the two rear wheels are still rolling freely does not help in the least. Thus in theory the ideal arrangement is to link the brakes diagonally; to have a brake on each wheel with the right-hand front interconnected with the left-hand rear and the left front to the right rear wheel. Then apply the brake however fiercely on either axle and there is at least one wheel that is rolling free and able to control the course of the car. Repeated tests both on models and on full-size cars have shown this diagonal system to vindicate the theory completely, the only trouble being in the mechanical layout of the connections for applying brakes in this way. As may be imagined, the linkage is somewhat complicated, and it remains still for some clever engineer to find a way out.

Steering Should Have Castor Action

Steering is faulty on the average car, because it requires too much effort. There is too much power lost in friction; and it also is inefficient because of absence of true castor action. The mathematics of castor steering are not complicated, but they admit plenty of room for discussion. While the front wheel with a central pivot, raked a little fore and aft, is the ideal, there are other ways of obtaining a similar effect; and it only needs to drive a car with perfect steering to appreciate what an enormous amount of additional pleasure it gives.

Few Cars Are Comfortable

Turning to quite the other end of the matter, another point that impressed most strongly at the show was the extremely small number of cars in which the seating was truly comfortable—that is, comfortable for an individual of normal stature. The number of cars in which an average-sized driver can sit at the wheel in an easy attitude when wearing a thick coat is almost to be reckoned on the fingers of two hands. There is a strong tendency to crowd the front seat right up against the cowl board and to stretch out the tonneau till the rear-seat passenger needs a megaphone if he is to be able to speak to anyone in the forward compartment. There has been a great wave of endeavor to make the body better looking from the outside; now it is time to turn to a rearrangement of the interior. That this is commencing is obvious. The cloverleaf body is the logical swing back of the pendulum from the "ballroom" style of tonneau, and it seems likely that the ultimate result will be a happy mean between the two. There were two cloverleaf bodies in New York that were comfortable for four people—and *only* two.

The Question of Wheels

To-day in Europe the wire wheel or the pressed steel wheel is the rule, wood wheels are the other thing, mainly because Europe has not got the right sort of wood. But the introduction of aluminum or celluloid disks to attach to *wire* wheels has led to the adoption of these disks for attachment to pressed-steel wheels also. A wire wheel is hard to clean even though it is mechanically superior to any other kind, and these disks make it into the easiest wheel to clean of any; so it looks just now as though disk wheels would become common in Europe. A disk wheel has many good points in its favor. It is simple to make and can be made very strong, while it can also be cheap to construct. Against it is the popular idea of what a wheel ought to be. Fashion has been conquered so many times that it counts for very little now; so the disk wheel, as a strong, simple and cheap idea, ought to be worth investigating. Probably the wire wheel by virtue of its mechanical excellence is going to be the ruling thing; but whether the disks are the true wheel or merely a wire wheel cover, their advantage when it comes to cleaning is well worthy of consideration.

Springs in Evolution

Another matter of design that seems to be in a doubtful state is that of springs. A year ago we heard all sorts of absurd claims made for the cantilever, rebutted by equally absurd arguments against it. To-day we see all sorts of springs giving just about the same service. The type of spring used on the Marmon and the Moline shows that there is still a possibility of new ideas in spring suspension, so this stands out as one of the things in which uncertainty still obtains. In the Fergus car, shown at New York, we see yet another spring idea that has waited for years to bring forth and is yet the simplest of common sense when you see it. Why not inclose a spring so as to keep it in its original condition of efficiency instead of leaving it open to the attacks of water and grit, which steadily reduce its efficiency, beginning from the first day the car goes on the road? Argued from this viewpoint, you might as well make a transmission with exposed gears as Levassor did for the Panhard company eighteen years ago.

Some Unexploited Possibilities

The subject upon which this paper is based is too large to do more than touch upon at present, but there are a few things beyond the little details already mentioned that are worthy of the engineer's occasional consideration. One possibility almost untouched is the two-stroke engine. The two-stroke seems a rational development, and yet it does not come. To many of us it is an everlasting puzzle to give the reason.

Those idle strokes in a four-stroke engine are poor engineering. It is poor science from the heat-engine theoretical viewpoint. So too is the unscavenged exhaust. The idea of leaving a third of the burnt gas in the cylinder to contaminate the fresh charge is bad from the ideal viewpoint. Yet in twenty years of trial nothing has been done that seems likely to exercise a great effect on automobile engines. There has been no special difficulty in the development of the two-stroke Diesel engine, and the four-stroke Diesel at least does scavenge properly, but the basic principle of the engines that drive the automobiles of 1916 is unimproved from that in use in 1896. If one sits down and ponders this point, the conclusion that we have not done all we might have done is inevitable.

Now, this has little enough to do with the automobiles at the shows, and yet it has everything to do with them, because the reason for mentioning it is that the automobile engines of 1916—the better examples, that is—seem to be very near the limit of efficiency that can be reached by the road we have followed for twenty years. The best engines now made could not be smoother in action, they could not be *much* less trouble to look after, they could not be *much* more durable or *much* more reliable. There are only two criticisms that can be leveled against them, and these are: (1) They could be lighter in proportion to their power; (2) They certainly could have a much higher fuel efficiency.

The second count is divisible into two sections. The present-day engine could utilize a cheaper fuel. If we have reached the limit of smoothness in operation, if we are near the limit in volumetric or in weight efficiency that is commercially possible, are we not also on the edge of what is possible with the carbureter as we know it?

It is easy to argue about reasons for the high price of gasoline, but whether it be due to a real shortage of supply or caused by financial manipulation of the market, the fact remains that we could run our cars much more cheaply if they would burn a heavy grade of kerosene. We have developed the really marvelous automatic carbureters of the day by lavish expenditure, and not a thousandth part of the money has been given to trying to find out how to use heavy oil in small engines. The automobile engine has been developed at such a wonderful pace largely because its fuel was comparatively easy to convert into gas; but we have done next to nothing to develop engines that will use fuels not readily gasified, to develop carbureters or similar devices for making gas from heavy oil. There seems no reason why the problem should be any more difficult of solution than many others automobile engineers have attacked and overcome in the past ten years. Is it not a worthy subject for study and experiment?

Conceive the immense selling argument for a car that would perform as well as those we know to-day and would do it on fuel at a quarter the price, or less, with a practically inexhaustible supply from which to draw. It must be worth while spending millions to achieve the end, and it is impossible to bring forward any fundamental reason why it should not be done.

Maintenance Costs Too High

The greatest point in which the present-day automobile fails in its purpose is that of maintenance cost. It is cheap enough to buy, but it is woefully costly to maintain. In obtaining the high gearability now demanded, the thermal efficiency of the machine as such has been neglected utterly. It was impressive to anyone on the lookout for sales arguments that hardly a stand attendant or salesman had a word to say on the running cost of his car. Nobody seems to be making this a strong point, yet it must be the most important point of all, ultimately.

We are well within sight of the time when the annual model idea will end. It is quite needless, it is wasteful in many ways, and so many manufacturers have broken away from the habit of changing their chassis at a stated time each year that the fiction of yearly series cannot be maintained much longer. Let a manufacturer introduce a new model as often as he likes, by all means; let him produce a new chassis as soon as he finds he can improve substantially upon the old one; but do not force him to make a new car at a fixed date. The novelty idea is almost dead as a sales argument. Cylindricity is ceasing to excite the buyer—this was particularly noticeable at the shows—and some new strong point is needed. Of the choice that offers, low maintenance cost seems to be the greatest, and in working toward this goal engineers will find they have their hands full for a lifetime.

In reducing maintenance cost there are two chief things for which to work, one the reduction of weight, and the other the reduction of frictional loss in transmission. On the weight-reduction scheme we are well started, and shortage of material is going to assist greatly in this direction. On frictional resistance hardly a beginning has been made. Excellent ball bearings and excellent roller bearings are bought and their efficiency thrown away by improper mounting or by careless assembly, and few of use ever pause to consider that a huge amount of power thus runs to waste every day. As a show attraction, it seems there should be a good opportunity to arrange a car in some way that will enable the pressure needed to start it moving to be demonstrated, something after the way in which one car at the 1915 show was exhibited on a scale which showed its actual weight.

The Ideal Car

In conclusion, though progress has been so rapid, we are still a long way from finality. Analyze the requirements of the 1916 buyer. He may not be able to sum up his ideals, but they seem capable of expression in the manner following.

The ideal car should have two pedals and a steering wheel. When power is wanted for starting, for speed, or for hill-climbing, press the power pedal; when it is desired to stop, press the retarding pedal.

At all speeds there should be *no* vibration and *no* sound.

Over all roads the car should roll without shock at any speed.

Its operation and maintenance should require no mechanical knowledge.

It should cost little to buy, and less to run.

If that is truly the ideal, are we not indeed a very long way from satisfying it utterly?

The automobile of the type we know is a wonderfully perfect machine, like the typewriter or the telephone; but like both it is marvelously imperfect, in that it is an immense distance away from what the human mind is capable of desiring it to be.

Government Issues Bulletin on CO Gas

RECENT cases of sickness and death due to carbon monoxide poisoning in mines and in garages has led the Department of the Interior, Bureau of Mines, to publish a pamphlet under the name of Bulletin 74, covering the subject of gasoline locomotives in relation to safety and health.

Important conclusions are reached in this booklet illustrating the relation of proper carbureter adjustment to the amount of carbon monoxide produced, and it has been shown in examining mine engines that the unskilled or careless motorman may use fuel enough to produce noxious gases and obtain about the same power as a skillful motorman obtains from a smaller quantity burned to a much smaller volume of comparatively innocuous gases. To illustrate this fact, a four-cylinder engine 5½ by 5 was made to develop full power at full rated speed and the amount of fuel was increased from 0.74 lb. to 1/18 lb. per brake horsepower hour. The amount of each of the noxious constituents, carbon dioxide and carbon monoxide, of the resulting exhaust gases of each of the several fuel rates, was accurately determined and the CO constituent varied from 2 cu. ft. at 0.74 lb. of fuel per brake horsepower hour to 9.5 cu. ft. at 1.18 lb. of gasoline per brake horsepower hour. The CO_2 constituent ranged from 6.8 cu. ft. at 0.74 lb. of gasoline per brake horsepower hour down to 3.5 cu. ft. at 1/18 lb. of gasoline per brake horsepower hour.

In giving the causes for the formation of carbon monoxide, which is the agent which causes the poisoning as well as suffocation, the bulletin states: "Carbon monoxide is the result of incomplete combustion of fuel. The combustion is affected by the relative quantities of air and gasoline, the completeness of vaporization, and of mixing due to the carbureter and manifold design, the degree to which the exhaust gas is mixed with fresh gas, the degree of compression, the timing of the ignition and speed of the engine, the adjustment of valves, temperature of jackets, lubrication, method of speed control, quality of fuel and probably other variables."

Belgians Build Huge Repair Depot

Factory 2700 by 1800 Ft. Erected and All Belgian Cars Collected For Overhaul and Reconstruction

By W. F. Bradley,

Representative of THE AUTOMOBILE *in Paris*

WITH all but a few square miles of her territory in the hands of the enemy, with all her automobile factories held by the Germans, with her Government established in Allied country, with half her population scattered, it is evident that the task of reorganizing the Belgian army is one that might cause the strongest men to quail. The fact that Belgium has not given up the fight, that she still declines to admit she is beaten, and that she has been and is still preparing to wage war on the invader, is the most heroic feature of the great world conflict.

The automobile section of the Belgian army is the one presenting probably greater difficulties than any other. There are no factories behind the service, and in consequence no more cars can be built and no more spares obtained for the automobiles still in a condition to be repaired. When any other of the warring nations approaches the automobile repair problem they have buildings, machinery, trained staffs and material at their disposal. Belgium has nothing.

Belgians Organize Repair Service

I have just been given an opportunity of seeing how, out of nothing, Belgium has got together an automobile repair service equal to that of any of her Allies or enemies. At a certain French seaport a big plot of ground was turned over to the automobile repair department. On this barren grass land overlooking the sea all the Belgian automobiles which had been abandoned in various parts of the country were brought in on freight trains. When I visited the ground there were two thousand of them, classified according to make, neatly lined up in the muddy field, battered and scarred and scorched and riddled by months of warfare and neglect.

When Belgium was invaded, every kind of automobile was thrown into military service. High-grade Minervas and Pipes and Savas, with bodies by Van den Plas and other artists, were made to carry muddied troopers, wounded men, raw meat, loaves of bread, barbed wire, horseshoes, anything and everything that an army can need in the field. When the cars broke down under the rough work and tremendous strain to which they were subjected, they were abandoned in farmyard or garage, by the roadside or in the ditch. With the reorganization period they were collected, brought to this nameless seaport in France, and entrusted to the repair staff.

Everything on wheels was brought along and made to take its place in the long lines of mechanical derelicts. Under a body which had been splintered by shell, scorched by the sun and rotted by the rain there might be a first class chassis ready for further service after a minimum of labor. Others were down and out. On the edge of the field I noticed an Overland, or what had once been an Overland. For wheels there were a few spokes, one half the rear axle had gone, the frame members were twisted and buckled, two cylinders were missing in the literal, and not the sense usually given to that word; the radiator had ceased to exist—the whole car was junk such as you never saw lying on the junk heap at home.

On that barren plateau overlooking the sea, Belgian soldiers had built huge all wood repair shops. The main building measures 600 by 900 yd., probably the biggest repair department under one roof the world has ever seen. No civilian, whatever his position or influence, was allowed to get within hailing distance of that building unless accompanied by a military officer.

Transport of Derelicts Difficult

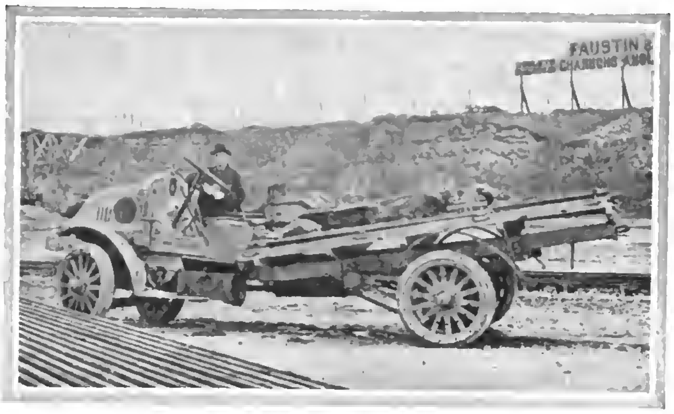
For automobiles to reach those buildings was not an easy task, for no roads existed. At the time of my visit American trucks, most of them 3-ton Kelly-Springfields, were hauling loads of stones from the beach about a mile away, dumping them on the roads which had been mapped out, while gangs of men broke them to suitable size, rolled them in and created a solid road.

Electric power and light had been obtained from the adjoining town. America, France and England had furnished the necessary tools and machinery. Belgium alone provided the labor. While the repair department was housed under one huge roof, the building was divided into bays, each one under a distinct staff and devoted to the repair of one particular type of automobile or truck. Thus, one section dealt with motor bicycles only; another built a standard type of ambulance body and fitted it to a certain make of chassis; another section handled nothing but American trucks; further on only Minerva cars were received and doctored.

American Truck Repairs Easy

The repair of American trucks constituted the least difficult of the many tasks the depot had to undertake, for sufficient spares have been ordered from the American factories and are available by the making out of a requisition form on the stores department. For the benefit of this service, special spare parts lists have been got out for each make of truck; every part has its description in French and carries a number, ordering from the stores being done by number only.

There is not the same simplicity about the repair of Belgian cars, for no factory can be called upon for spares. However, many of the engineers of the leading Belgian factories are available and under their directions most of the commonly required parts for the leading makes of cars are now manufactured.



How a Kelly-Springfield looked after a 60-ton load dropped on it

Engineers Take Charge

The staff is military, but the officers have the assistance of engineers from the home factories. Thus, the highest civilian authority in the shops is an engineer who before the war occupied an important position in the Pipe factory at Brussels. One of the greatest difficulties the Belgian authorities have had to contend with in their reorganization scheme is that of securing adequate skilled labor. Expert mechanics are not going about Europe with their hands in their pockets at the present time. Men not eligible for military service can earn higher wages than at any time in the history of the engineering industry, while those who are under the direction of the army authorities are not allowed to waste their efforts. Belgium has never had the same stringent compulsory military service as France and Germany, very few of her married men even now being obliged to serve in the army. Thus, when the country was invaded, the workers in the engineering trades who escaped to France and to England found plenty of work awaiting them, and are employed at the present time in the factories of these two countries.

The staffs are made up of young mechanics still

Pierce-Arrow traveling repair shop

Getting an Isotta-Fraschini tractor out of a gully on the Italian front

A Lancia standing by an overturned Fiat on the Italian front. The Fiat eventually was raised to the road by a repair crew and, after undergoing a few repairs, was returned to service

eligible for military duty, of engineers and mechanics who volunteered for active service when war broke out and have since been drafted into the army repair department, and of old men for whom the active army has no further service. Even these men, if they are of real value, can only be got by competition with the English and French shops, and as these shops were the first to enlist the skilled refugees it is not an easy matter to get them transferred.

It has been necessary, also, to deal with the younger men of military age, but with no technical experience, who would prefer to be in the workshops rather than in the line regiments. Many of these used whatever influence they possessed to have themselves posted as skilled mechanics, but a few minutes in the shops was sufficient to show that they had everything to learn about mechanics and automobiles. Restrictions have had to be imposed to keep out these young men whose knowledge is based on imagination. A considerable amount of dilution of skilled labor has had to be adopted, a skilled foreman being put in charge of each department, and each skilled mechanic having two or three unskilled or semi-skilled men working under him.

With the completion of her central automobile repair depot the Belgian government will be able to relieve those French and English automobile factories which have for months past been occupied on Belgian repair work. The factories can thus devote all their energies to material for their own armies. The centralization, too, simplifies shipping and control, it being an easier matter to send damaged cars into one central depot within easy reach of the Belgian lines, than to distribute them among a series of automobile factories in various parts of two countries.

Pierce Trucks Make Traveling Shops

By the British army numbers of the Pierce 4-ton trucks have been fitted as traveling workshops for the convoys to which they are attached. No change is made in the chassis, which is fitted with a platform body with permanent top and a separate cab over the driver's seat. One half of each side and rear hinges down so as to extend the floor space and the other half hinges up. Waterproof curtains are fitted to the extension top and can be lowered so as to prevent rain and sun beating in. Each repair shop is regularly fitted with a Douglas two-cylinder opposed motor direct connected to an electric generator. The machinery consists of an electrically driven screw cutting lathe, a heavy electric grinder, an electric overhead drill, a small foot-power speed drill, a substantial work bench, also flexible connections for portable drills, electric light sockets, etc. The usual plan is to supply one of these repair shops to a fleet of forty to forty-five trucks.

Several are working in this way with the anti-aircraft brigades scattered along the British front in France and Belgium. These brigades comprise heavily armored cars equipped with a new type of machine gun.

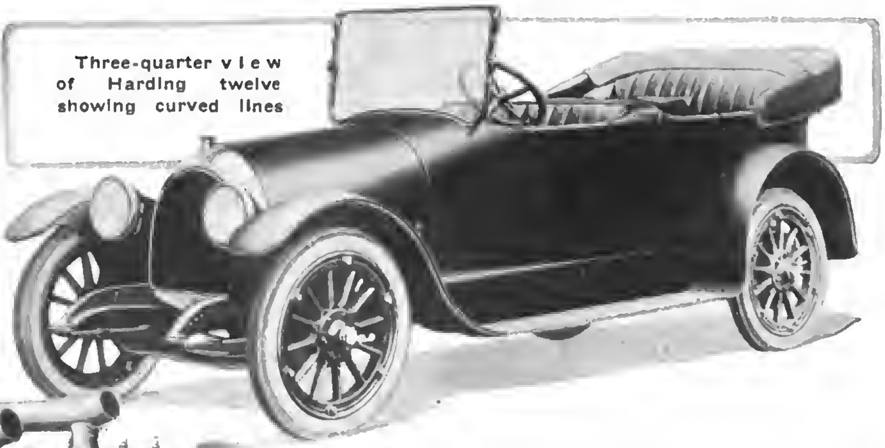
Harding Body Design Distinctive



Three-quarter view of Harding twelve showing curved lines

Side view of Harding twelve motor showing removable heads and the light and starting units

THE latest automobile announcement from Cleveland is the Harding twelve, made by the Harding Motor Car Co. This car is rendered distinctive by its foreign body design. Instead of the straight lines of the streamline type, curves have been used, blending into each other from the radiator through the hood, cowl and body to the rear. The car has a wheelbase of 132 in. and the body a comfortable seating capacity for seven.

The Harding motor is of the twin-six type. Cylinders are cast in two blocks of six each, and mounted on separate crank case at an angle of 60 deg. The cylinder heads are removable. The motor is 2¾ by 5, of the L-head type. A single camshaft with twenty-four integral cams is used. Lubrication is by the pressure system.

1916 Empire Four Now Lists at $935

THE Empire Automobile Co., Indianapolis, Ind., has made a few changes in its four-cylinder car. Known as model 45, it differs from the preceding model especially in its wheelbase, which has been lengthened 4 in. to 116 in., and also in its price, which has been increased from $895 to $935. Another change of importance is the adoption of semi-elliptic rear springs in place of three-quarter elliptics. A new brake arrangement has also been incorporated. There are two sets of brakes, internal expanding and external contracting, operating through an equalizer system. The hand brake is attached to the equalizer by flexible steel cable. The foot brake rod is in two pieces, the first section connecting the pedal to a lever on center cross member with another rod from this lever to the equalizer. By this construction the use of countershaft is made unnecessary and brake rod rattle is eliminated.

The rear drive is of Hotchkiss type, drive being taken through the springs. The rear axle is Weston-Mott full-floating single bearing type. Drive shafts are chrome nickel steel, 1¾ in. in diameter and propeller shafts 1⅝ in. in diameter. Hyatt high-duty bearings are fitted throughout.

The gasoline tank of the new model has been enlarged to carry 17 gal. as against 14 in the preceding model. The streamline body conforms very closely with the Empire Six. Exceptional leg room in both driving compartment and tonneau is a feature. The front seat is 38 in. wide and rear seat is 47 in. The cushioned seats are upholstered in Spanish leather. The doors are full U-type, 21 in. wide with concealed hinges and handles.

The standard body color is autumn brown with wheels and running gear to match. In addition to this any desired color is furnished upon order.

The equipment is complete in every detail. In addition to the two-unit starting and lighting system, there is a Willard three-cell six-volt storage battery, and a one-man top covered with DuPont Rayntite material. A tire pump is furnished at extra charge.

In addition to the foregoing equipment headlights with powerful searchlights for country driving, tail and tonneau lights, rain vision, ventilating windshield, Stewart speedometer, dash carbureter adjustment, etc., are furnished.

Weight Eliminated in Peerless Eight

Unit Power Plant with 90-Degree V-Motor Gives Compact Layout—Reducing Lever Arrangement on Clutch Pedal Gives Easy Throw-Out

IN making the radical change of policy noted in the Peerless line for 1916, the engineers of this company claim that they have produced an eight-cylinder car which has performance qualities equal to the six-cylinder 60-hp. car that was a feature of the line for several years. At the same time the mileage per gallon of gasoline has been doubled and the tire cost is claimed to be but one-third of what it was for this former model.

These two results, greater economy and better performance, mean that there must have been developments along the main line of engineering improvement in motor and chassis design, *i.e.*, lightness. With this thought in mind the Peerless car becomes an interesting engineering study, because it shows the results obtained by a concern which has been building cars since 1902, or fourteen years, with a design of car that is markedly different from previous models yet which, after all, is founded on the experience gained in that time.

The group of drawings shown on this and the next two pages illustrates the model 56 Peerless. The power plant, which is a V-design, has two groups of four cylinders mounted at 90 deg. between the axial planes of the two sets of cylinders. The dimensions of the power plant are 3¼ by 5 in. and the rating is 33.8 hp. The Peerless company claims a horsepower output of 80 at 2700 r.p.m.

Staggered Cylinders Used

The two sets of cylinders which are each cast complete are offset to a sufficient degree to permit of a side-by-side connecting rod mounting on the crankshaft. This arrangement is shown clearly in the part longitudinal section of the motor. As will be noted, the lower connecting rod bearings are independent, and can be adjusted separately if desired. The bearing pressures with this arrangement will not be excessively high, as the comparatively small cylinders will not give an abnormal thrust due to explosion pressure. The main bearings are three in number and are quite long. The bearing bridge supports are hung from the upper part of the crankcase and are of web structure, giving light weight with stiffness and providing a cored passage for the lubricating system.

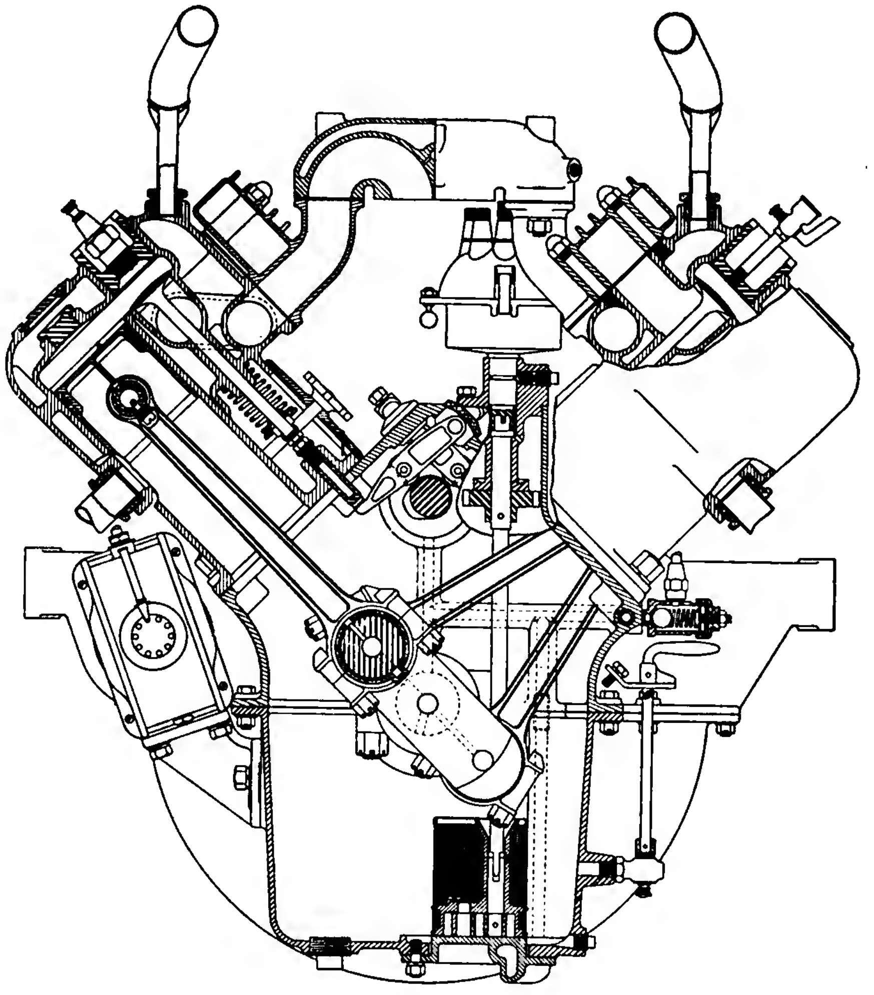
I-beam section connecting rods are used with two-bolt lower ends. The bearings are bronze-backed at the lower end and at the wrist pins the rods operate on phosphor-bronze bushings.

Three bearings are used to support the single camshaft which is located at the upper extremity of the crankcase on the longitudinal center line. There are sixteen cams on the shaft and the valves are operated by finger lifters with roller cam followers. The finger is pinned at one end and has the lifter end at the other extremity, the roller follower being in the center, so that the cam action is approximately multiplied by two, through the finger-lever lifter arrangement. The contour of the cam shows that the valves are given a quick opening, although the cam is not square enough to produce follower hammering. The contour of the cam can be noted in the transverse motor section.

The valves are located in the V, or in inside position, as is natural with the single camshaft arrangement. The individual cylinders are L-head, and the customary arrangement of the standard L-head type has been followed through as far as possible, consistent with eight-cylinder design. Valve stem clearance adjustments are made by lifting a cover plate after removing wheel nuts in the inside of the V.

Oiling System Is Full Pressure

Full force-feed lubrication is employed to carry the oil to all the bearings of the crankshaft and camshaft. Oil is drawn through a cylindrical screen at the lowest point of the crankcase. The oil pump is located in the base of the crankcase and consists of two bronze gears driven from the camshaft. Oil is discharged from the pump into a cored passage which leads to a distributing tube in the upper part of the crankcase, and from the tube independent leads run



Part transverse section through the Peerless eight-cylinder motor for 1916 to each of the bearings, sufficient oil being forced to take care of all the bearing surfaces. The remaining oil passes through the regulating valve which is illustrated in the longitudinal motor section and passes to the timing gear case. Its function here is to lubricate the gears and gear bearings, and, in addition, there is a marked cooling effect on the oil due to its contact with the extended gear case. The passage for the oil to the crankpins is by way of the drilled crankshaft, and after lubricating gears and bearings, the oil returns to the crankcase, where it is strained and recirculated.

A feature of the motor is the ample waterjacket space, and this will be noted over the heads of the cylinders, a point which is sometimes slighted in the endeavor to reduce height and secure compactness. The circulating medium for the water is a double water pump system, which insures equal distribution of the water to both cylinder blocks. Air is drawn through the flat-tube radiator by a six-blade fan and a special provision for free air discharge is made by having ample space between the motor and the sod pan. Cooling ribs are cast on the exterior of the exhaust manifold to cut down the temperature of the metal.

An interesting feature is the mounting of the tire pump which is on a continuation of the fan shaft. The fan shaft is continued back and terminates in a lever-operated clutch which controls the engagement of the single-cylinder, vertical air-cooled pump mounted between the blocks of cylinders in the V. The fan is driven by a train of spur gears which form part of the timing assembly group mounted in the casing at the front end of the motor.

Clutch Has Light Action

In carrying out the general scheme of lightness and compactness, a special study has been made of the clutch and gearset. These parts form, with the motor, a unit powerplant. The clutch part of the unit is a dry multiple disk, faced with fabric on alternate disks. Easy but firm engagement is secured by a double concentric coil spring with a tension control nut for adjustment. The clutch is a small unit and is contained in a housing which is inclosed within the flywheel. When the clutch is disengaged the clutchshaft rests on an aligning ball bearing in the center of the flywheel. Very small pressure is needed to release the clutch, owing to the use of the multiplying levers shown very clearly in the illustration of the pedal assembly.

Behind the clutch, in the same housing, is the three-speed gearset which has the main shaft carried on roller bearings and the secondary shaft on annular ball bearings. A feature which is worthy of favorable comment is the mounting of the shifter lever which instead of being in the exact center of the gearbox coverplate, is mounted at the rear end. This brings the shifter lever closer to the driver's seat and aids in making the car comfortable to drive. The shifter lever is connected at the bottom with a ball rocker mechanism through which the shifts are made. The emergency lever is mounted to the side of the shifter lever. Over the center of the gearbox is an oil hole which is fitted with a breather.

Final drive is through a roller-bearing mounted spiral bevel-drive rear axle of floating design. The shaft is tubular and is equipped with two universal joints. The type of drive is the Hotchkiss, as both torque and propulsion thrusts are taken through the rear springs. The brakes are double concentric working upon a single drum.

The specifications for the standard car give the wheelbase as 125 in. and the wheel size as 34 by 4 in. The tires fitted, are the oversize 35 by 4½ in. straight side cord type. The standard touring car sells for $1,890.

CONDEMNS BODY DESIGN AND CONSTRUCTION—SUGGESTS OTHER IMPORTANT DIMENSIONS—CONSIDERS SUBJECT OF GREATEST IMPORTANCE

Modern Body "Tin and Imitation Hair"

By Finley R. Porter

I HAVE read the article on the subject of "driver's comfort" in THE AUTOMOBILE for Feb. 3 with interest, and my greatest criticism of it is that the cars are numbered instead of mentioning names.

There has never been any one thing in the automobile business, to my notion, that has caused so much expense, dissatisfaction, and has had more to do with the so-called public demand, than this topic of "driver's comfort." I think too, that the word "comfort" should be displaced by "possible operation," since comfort is not in the question at all. Neither does the ability of the different designers enter into it because they all know better, but the main governing factor is price.

This whole subject is to my mind a clear illustration of the fact that you cannot build an automobile for $1.50. What can be done and is being done, is the assembling of the frames with radiator, wheels and axles together with a little tin, imitation hair and leather commonly termed a body, which one can—by resorting to the numerous contortions mentioned by Mr. Schipper—manage to have it propel itself from one place to another, but so far as calling it an automobile and expecting any degree of comfort, I think it is absurd.

All of the magnetic transmissions, electric gearshifts 4½ to 1 gear ratios, and the general feeling that the public cannot be educated to shift gears are the result of this very thing.

The answer does not lie in adding up the different deformities and dividing them by the number of cars built, since the users range in size from the midget to the giant, and anything attempted as a universal fit is just as ridiculous as it would be for a clothing establishment to try to sell one size suit of clothing to all.

As long as the public are satisfied to expect something like this and pay about $1.50 for a dollar's worth, I think it would be wasted effort even to argue about the matter with the idea of getting the people to try and strike a happy medium.

What I think should be done if anything, is to compile a set of figures for the different measurements that would produce driving comfort and easy operation, that would be in a given proportion to actual measurements from an individual taken as an example. These measurements would of course vary with different individuals, but would remain in a constant proportion, so that any man knowing his own measurements could easily eliminate a great many cars from the list of possible purchases by comparing the actual measurements to the different cars if they were published.

Comfort Partly Imaginary

In the case of a man having his own body built, he most always gets a fit to suit himself, but in a great many instances he doesn't know what is needed, but finally accustoms himself to the body he gets and as a rule firmly believes he is realizing extreme comfort while in a great many instances he is about as far from it as it is possible to get, but the fact cannot be charged up to the designer. There is scarcely any possible way of having adjustments to fit the different individuals because any one measurement is about as vital as another.

Some of Mr. Schipper's deductions such as the added life of the car due to perfect operation are very true, and if the public could only be educated to the point that by paying an additional hundred dollars for their car and having it fit them, a material saving would be had, and they would probably see a great improvement so far as comfort in operation goes. The impossibility however of such procedure seems almost certain, in view of the fact that the tremendous productions coming from some of the factories would cost practically twice as much if the cars were made to somewhere near fit the individuals using them.

Left Drive a Fallacy

The question of getting in and out of the left hand drive cars is one of the many things that make me wonder why they still feel they should have the left hand drives. It is the most impossible of all the changes that have come about in the past few years when considered from the points of advantage claimed for it. It is of course just as easy to make a car drive from the left as the right if the only object is to change the position of the driver, but so far as any real advantages that are being claimed and stuffed down the public's throat, my contention is that there is absolutely nothing to it so far as the operator is concerned.

My belief is that to discuss the subject, the car that is under consideration should be named and attention called to the discrepancies found and ask the manufacturer to defend himself. I imagine this line of procedure would produce replies from the people concerned that would have the little incident of Washington and the hatchet discounted.

Pierce Body Dimensions Carefully Chosen

By D. Fergusson,

Chief Engineer, Pierce-Arrow Motor Car Co.

MR. J. E. SCHIPPER'S article in your issue for Feb. 3 deals with a very important subject and is one, as the author stated, that has been given very little consideration by automobile manufacturers. We ourselves have endeavored to give as comfortable a position as is possible, without curtailing the room behind the driver's seat. We are inclosing a sketch showing the room for the driver and the front passenger in our standard touring car. You will notice these conform fairly closely to Mr. Schipper's ideas, with the exception of the distance from the underside of the steering wheel to the top of the cushion. We feel that Mr.

Schipper is wrong in asking for as much room as he does in this location, as we find that our allowance is ample.

It must be remembered that the cushion is quite soft and that the driver sinks into it an inch or more when in position, thus giving one or more inches over that which we give. For the low position that some few drivers desire, an entirely different arrangement of seat is necessary. We are only giving you our standard touring car dimensions.

Suggests Another Dimension

By W. G. Wall

(Chief Engineer National Motor Vehicle Co.)

IN regard to Mr. Schipper's article about driver's discomfort, would say we realize this is a very important subject and that it has not been given the attention it should. At the same time the public do not seem to understand that there is a limit to these dimensions; for instance: the standard tread of rear wheels limits the width of rear seat cushion unless the seat is made very high, and the length of wheel base limits the distance from the back edge of rear door to the front of cowl, this distance having to be divided up into the hood length, the front room for driver and the width of rear door and of course all manufacturers are anxious to keep the wheel base as short as they can get results; whereas an owner wants a car at as low a price as he can get it, one which is very light, has a short turning radius, and in fact everything pertaining to a short wheelbase, whereas he wants the comfort of a long wheelbase.

I do not quite agree with Mr. Schipper, however, in some of the dimensions which he takes as the most important ones. While some of these are the important ones, he does not give the most important. The most important dimension we consider is the one from the back of front seat to the foot pedals. The distance from the front of the front seat to the foot pedals does not give what is wanted, as the depth of front seat might be anywhere from 18 in. to 24 in. Also the distance of the levers should be given from the back of front seat.

Another dimension we think is important is the distance from the back edge of rear door to the back of the front seat. The door itself may be very wide, but if part of it overlaps the front seat, as a great many do, the entering distance would be very narrow.

There is a great difference, however, in what drivers consider comfort. Some think they should sit up high to be comfortable, and others think to sit low is the most comfortable position. Personally the writer would say that something between these two extremes is preferable.

Also the distance that the seat should be set back varies so much with the height of the driver and the length of his legs that we have found the only feasible way was to make the driver's seat adjustable, and even that only remedies part of the trouble.

We think the points Mr. Schipper brings out are very good and are certainly worth regarding by the manufacturer, but, as before stated, there is absolutely no way of securing all that is desired for different drivers without making several of the parts adjustable, which is not always either practical or possible.

Battery Mountings Should Be Accessible

Rigidity Now Generally Secured, but Ease of Access Means Prolonged Life on Average Car

WITH each succeeding year making the battery more the keynote of happiness as far as car ownership and drivership is concerned, the development of accessibility in locating this important unit is assuming a great importance. It must be conceded that the battery is not an ornament, therefore it must be out of sight. It must also be conceded that it is a utility whose efficiency is maintained by attention and therefore it must be located where it can be reached with the least delay. The two circumstances are not at all incompatible and the page of examples shown here are all good, although it must be admitted that some are better than others from the accessibility standpoint.

The designer must remember in laying out car parts that the car, for most people, is an implement of entertainment. It is occupied largely in a spirit of relaxation. Any work that has to be done on it is considered at least by a large percentage of owners, among whom the tired business man is strongly represented, as a great nuisance. Since the work itself is a nuisance, the lifting of seat cushions which are held within quite narrow limits by the steering column and the performing of other similar tasks will often promote a spirit of procrastination that keeps the hydrometer and the bottle of distilled water on the shelf instead of in the hands of the owner.

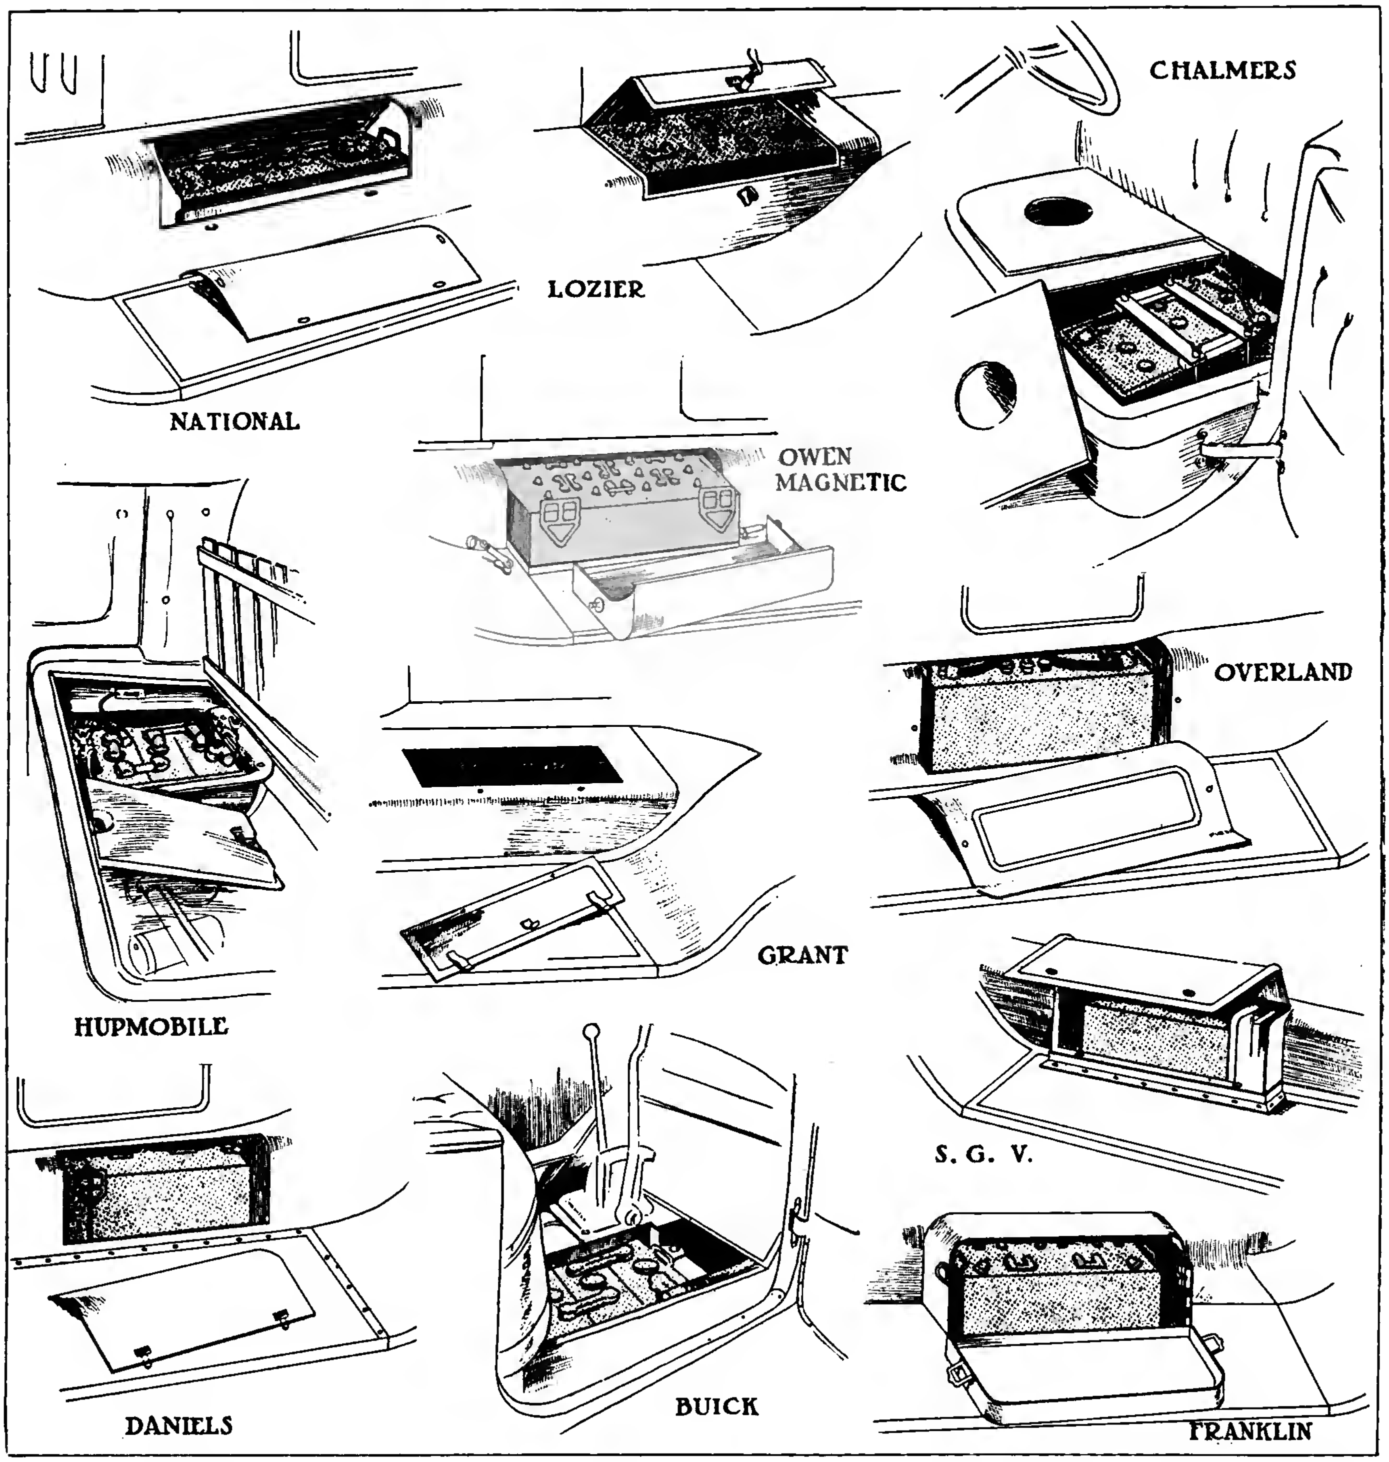
Importance of Detail Care

It has been said that the average American takes his pleasures sadly. If this is a national psychological characteristic, and if the automobile be reckoned among the pleasures, then it behooves the designer to remove as much of the sadness as is possible by turning the searchlight on the little details which help to make the car a comfort. In fact, they cease to be little details if thought is directed to what the results of inaccessibility are. In the case of the battery, the life can be lengthened 100 per cent by careful attention. On the other hand the amount of attention can be reduced immeasurably by having the battery in a place where it is out of reach. The difference in convenience is quite apt to mean the step from satisfaction to the opposite with the electrical service on the car.

Battery makers direct that distilled water should be added to the cells every thirty days. With an inconvenient battery location this will often be stretched to double the time solely on account of the owner's neglect. When the battery plates have gone bad and an adjustment is demanded, the owner will not always be accurate regarding the amount of care that he has spent upon the battery. On the contrary, the fact that he has dug two or three times into the depths of his car and filled the battery will be so impressed upon his mind that he will think he has been over-zealous rather than careless in doing his share toward battery maintenance. If the battery is so located that it can be reached without disturbing any part of the car besides the coverplate, it will be attended to much more frequently.

Mistakes were made quite frequently during the last two years on insufficient rigidity in battery mounting, but that time has about past and the examples of where the battery is apt to shake loose on rough roads are quite scarce. It may be mentioned in passing, though, that there are still a few examples of where the rigidity feature can be given somewhat better attention. The method which has been used with success by many is to employ a metal strap very much like the strap used on magneto mountings. This is fastened by taking up on a nut which pulls the strap tightly over the battery. At the same time the accessibility question as regards removing the battery for repairs is not overlooked. In securing the rigidity it must not be done at the expense of making it a great task to remove the battery from the car.

Miscellaneous 1916 Battery Mountings



Accessibility Made a Study to Promote Care of Battery

THE battery mountings shown above are representative of the practice on 1916 cars. It will be noted that these are a considerable improvement over the methods used in 1912 when it often took as long as 15 min. before the driver could get into such a position that he was even able to see the battery. The filling of the cells with distilled water was often neglected in the older cars simply because it was a difficult task to get to the battery without encountering greasy parts which would destroy any clothing that was not intended to be worn in the workshop.

The installations above show that the subject of accessibility has been made a careful study and the results have been well worth while. The battery is kept out of sight and at the same time it is in such a position that the driver can reach it readily. One of the important considerations in placing the battery is that the wiring is well protected.

The Rostrum

Aluminum Pistons Reduce Inertia Forces

EDITOR THE AUTOMOBILE:—I have a model 79 Overland touring car and am thinking of equipping the motor with aluminum alloy pistons.

1—In general, would you advise this change?

2—Would it materially reduce vibration at the higher car speed, say 25 to 45 m.p.h.?

3—What clearance should the pistons have?

4—Should oilways be provided?

5—Do the wristpins need any particular attention due to the higher thermal capacity of the alloy piston?

6—Will carbon form on alloy pistons as readily as on cast-iron pistons?

7—What compression should the above motor have when in first-class condition?

Massina, N. Y. L. O. V.

—In general aluminum pistons materially reduce the vibration in a four-cylinder motor, especially at the high engine speed.

2—It would be within the speed range you mention that the effect would be noticed.

3—Clearances should be approximately twice those of the present iron piston.

4—Yes.

5—It is possible that the wristpin should be fitted a little more tightly when cold.

6—Provided there is not excessive lubrication the carbon deposits should be less.

7—The model 79 Overland motor when in good condition should show 65 lb. compression on gage.

Tests Must Be Made in Laboratory

Editor THE AUTOMOBILE:—Is there an accurate instrument made for testing water in a radiator to which denatured alcohol has been added to ascertain at what temperature it will freeze? If so, please describe it and how it works.

Washington, D. C. H. M. B.

—This is a straight laboratory test. The devices used are simply a container for the mixture and a thermometer. The temperature is reduced by means of a refrigerating machine until the mixture begins to freeze, when the reading on the thermometer is taken. Hydrometer readings when the mixture is correct give a key to evaporation losses.

Four-Wheel Drive Not for Passenger Cars

Editor THE AUTOMOBILE:—Why do not passenger automobiles use the four-wheel drive and what are its disadvantages?

2—Would it be practical to use a fan on a snow sledge for the main drive? Would there be any loss through slippage?

3—How many miles does an aeroplane go on a gallon of gasoline? B. J.

Wolverton, Minn.

—The purpose of the four-wheel drive is to secure traction at both the front and rear ends of the car. Naturally it is going to call for somewhat more complicated mechanism than the two-wheel drive, where traction is only secured at the rear. Since in the passenger automobile it is desired to keep the vehicle as light as possible, the four-wheel drive would hardly be used; while for heavy trucking work, especially in difficult country, it might be very desirable.

2—It would only be possible to use a fan on a snow sledge for the main drive if the sledge were extremely light and worked over the surface of the snow and not through it. The loss in any case through slippage is enormous, as it is in any form of aerial propeller work.

3—This varies through such an enormous degree with the different types of machine that it is impossible to give you any answer. There are some machines which do not travel over two or three miles to the gallon and others which travel fifteen or twenty. The distance traveled also will vary with the wind, whether the machine is climbing or descending, and a great variety of other disturbing elements.

Fastest Mile Ever Made on Motorcycle

Editor THE AUTOMOBILE:—Reading over your magazine inquiry of C. E. G., Charlottesville, Va., in the Rostrum, dated Dec. 16, 1915, about the fastest mile ever traveled on a motorcycle, I believe the famous Curtiss mile, to my knowledge, is the fastest mile ever made on a motorcycle.

This was an eight-cylinder, 40 hp. Curtiss motorcycle, driven a mile in 26 2/5 sec., by G. H. Curtiss at Ormond Beach, Jan. 23, 1907. FRANK H. LUMPE.

Del Monte, Cal.

Cadillac Eight-Cylinder Firing Order

Editor THE AUTOMOBILE:—How does a Cadillac eight fire?

2—What is meant by 3.750 to 1 and 4.00 to 1 ratio?

3—Can an Overland 80 model go 18 to 20 m.p.h. on first speed?

4—What is the speed of an Overland 80 engine?

5—What is the speed of a Hupp 32 engine?

Camden, W. Va. J. C. C.

—The order of firing of the Cadillac eight is as follows: First No. 1 cylinder on the right, then No. 4 on the left, No. 3 right, No. 2 left, No. 4 right, No. 1 left, No. 2 right, No. 3 left.

2—These ratios indicate that the crankshaft rotates respectively 3¾ and 4 revolutions to 1 revolution of the rear wheels.

3—Yes.

4-5—These speeds depend altogether on the condition of the motor, and vary to such a degree that THE AUTOMOBILE cannot give such figures. The maximum speeds, however, are probably close to 2500 r.p.m.

No Official Ford Consumption Record

Editor THE AUTOMOBILE:—What is the best official record of m.p.g. of gasoline for a Ford car?

2—With what carbureter was this made?

3—Was the claim of 44 miles per gallon of gasoline for a Ford, made by the manufacturer in Detroit recently of an auxiliary air button, substantiated?

4—Why cannot a good modern automatic carbureter give as many miles per gallon without the use of any separate auxiliary air device?

5—With the proper heating of the mixture will a Ford motor run properly and satisfactorily on kerosene, having at first been started on gasoline?

6—It is claimed that the motor will overheat and that the running on a kerosene mixture is otherwise detrimental to the motor. Is this true?

7—Does heating of the gasoline before it enters the carbureter facilitate better combustion—this in addition to taking in heated air? C. C. W.

Huntington, N. Y.

—THE AUTOMOBILE has no knowledge of any official records of gasoline consumption with a Ford car.

2—The standard Ford cars are equipped with Holley and Kingston carbureters, and an average of 20 miles per gallon should be obtained if the carbureter is properly adjusted. It is not uncommon to secure from 25 to 30 miles per gallon on fine adjustments.

3—There is no record of any sanctioned trial by recognized officials on a test of this kind.

4—No doubt the same results could be obtained with any dash control carbureter.

5—Yes, provided proper vaporization is maintained.

6—No.

7—The heated air method is probably more satisfactory without the heated gasoline except after it reaches the carbureter. Care must be taken in pre-heating the fuel not to rarefy the charge.

Cadillac Horsepower Curves Are Similar

Editor THE AUTOMOBILE:—Kindly give me the power curves of the 1915 and 1916 Cadillac eights? H. W. F.

Burlington, Vt.

—The horsepower curves for the 1915 and 1916 Cadillac eights are similar. The curve is shown in Fig. 1. It was incorrectly given in THE AUTOMOBILE of Feb. 10.

Heat Required as an Aid to Carburetion

Editor THE AUTOMOBILE:—Would like to obtain information regarding the adjusting of a Schebler model L carbureter.

2—Would this make of carbureter, being water-jacketed, work better than one which was not a water-jacketed carbureter? R. C. G.

Monroe City, Ind.

—With the present grade of gasoline the more heat that can be applied to the fuel the better results are obtained. It is recommended that you use an exhaust sleeve or drum around the exhaust manifold and flexible tubing running to the air bend of the carbureter. Heat applied at this point gives the best result.

2—Where the carbureter has a hot water jacket it is advisable to tap the exhaust and run a pipe from the exhaust to the jacket of the carbureter. In this way the exhaust heat will warm the carbureter jacket, or, if it is convenient, the hot water can be piped to the carbureter jacket. It is easier, however, to utilize the exhaust heat. With the present grade of fuel it is very necessary to heat the carbureter in the region of the primary nozzle, and it is especially essential that the low speed air be warmed.

Reduction Equals Ratio of Gear Teeth

Editor THE AUTOMOBILE:—Kindly enlighten me how to figure gear ratio of a drive pinion of an auto with twelve teeth and a ring gear with forty-three. As I understand, the answer is 3.58.

Also show me how to figure the gear ratio of a transmission that has twenty-six teeth on the countershaft and twenty-one on the sliding shaft or drive shaft; on the intermediate gear on the low there are twenty teeth on the countershaft and twenty-seven teeth on the sliding gear.

Also inform me how to figure cubic inch displacement of a motor 3⅝ by 4½. I have seen these examples worked in algebra and that is something I know nothing about. Is there any other way to figure it? T. A. E.

San Francisco, Cal.

—The method of figuring the ratio of a train of two or more gears is to take each number of gears that mesh and divide the number of teeth in the driven gear into the number of teeth in the driving gear.

The gear reduction of the whole train is the product of all the ratios of the intermediate gears.

Piston displacement can be easily calculated by arithmetic without the use of algebra. Simply multiply the diameter of the cylinder by itself, then multiply by 0.7854 and multiply again by the length of the stroke. This will give the piston displacement for one cylinder. For the whole engine simply multiply by the number of cylinders.

In the motor you give, the piston displacement would be calculated by the following example: 3⅝ x 3⅝ x 0.7854 x 4½ x the number of cylinders, which you do not mention.

If it is a four-cylinder engine the displacement is 185.8.

Tractive Power Formula Explained

Editor THE AUTOMOBILE:—In the issue of Dec. 16 there appeared this formula for determining tractive power:

$$VC = \frac{8.4 \times n \times b^2 \times S \times R}{D \times W} \times em \times et$$

Where *em* is the efficiency of the motor as compared with the S.A.E. rating as unity, I would like to have this term explained. H. S. J.

Mill Valley, Cal.

The formula given above may be divided into three parts, the fraction, the term *em* and the term *et*. In the fraction it is first presumed that all motors will develop a torque in pounds at 1-in. radius equivalent to that of their N.A.C.C. horsepower rating, assuming that the mean effective cylinder pressure is 90 lb. per square inch, and the piston speed at 1000 ft. per minute. The term *em* gives the correction for any particular car. The average value of *et* × *em* for a large number of cases tried figured out to be 0.95. A more complete discussion of the question may be had by referring to the S.A.E. Bulletin for July, 1915.

Bad Mixture Causes Motor Cough

Editor THE AUTOMOBILE:—I have noticed sort of a coughing sound coming from the exhaust of a Ford motor. It sometimes seems to be between explosions. It is sometimes irregular and sometimes regular. What is the cause of this?

2—What will cause a light irregular knocking or tapping

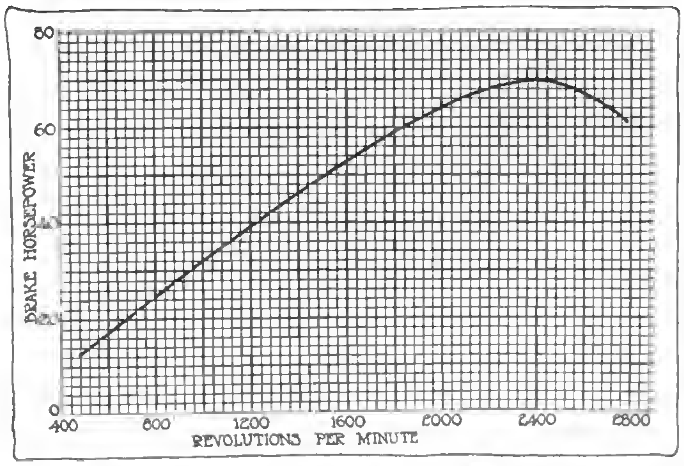


Fig. 1—Horsepower curve for 1915 and 1916 Cadillac eight motors

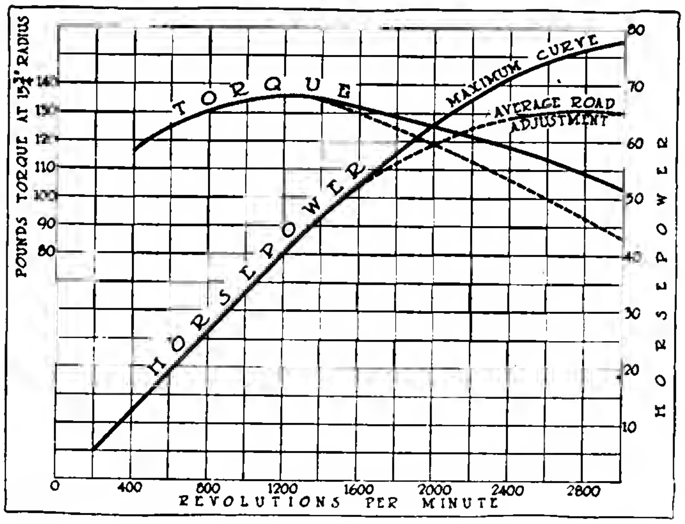

Fig. 2—Horsepower and torque curves of twelve-cylinder National

sound in a Ford engine? The noise is only evident when the engine is well warmed up with the spark in correct position and free from carbon. It is not very noticeable on hard pulls. H. & S.

Brownell, Kan.

—The coughing sound is due to an improper mixture, either too much or too little gasoline being supplied.

2—It is difficult to give the cause of a knock from the information you supply. The trouble, however, may be the result of a valve slap caused by too great clearance between the pushrod and valve stem. It can be remedied by replacing these parts. The cause also may be a loose wristpin.

Horsepower Curve of Twelve Motor

Editor THE AUTOMOBILE:—Will you kindly send me the horsepower curve for one of the following twelve-cylinder engines: Weidely, Enger or National?

Sandusky, O. L. D. D.

—The horsepower curves of the Weidely and Enger twelve-cylinder motors are not available. That of the National twelve-cylinder is given in Fig. 2.

Valve Clearance Set on Closed Valves

Editor THE AUTOMOBILE:—In setting the clearance of valve lifters on a 14-38 Packard can the valves of more than one cylinder be set at one time or do you set them one, two, three and so on?

2—How many explosions take place in one revolution of the crankshaft in a twin six Packard? How many in a 14-38 Packard, and please explain:

3—Do you favor putting denatured alcohol in the petcocks when the motor is hot in order to clean out carbon?

4—What is meant by the tread of a chassis?

5—I find on a cold day after standing a while it is hard for me to shift gears. I use oil in the transmission and differential. What is the cause?

6—Is it harmful to pour a little steamer oil in the radiator to lubricate the water pump?

7—How much alcohol would you put in a radiator holding 6 gal. to keep from freezing?

8—How would you proceed to treat a car that is frozen?

Brooklyn, N. Y. W. C.

—The valve clearances can be set on all the valves that are closed.

2—The explosions per revolution in a four-cycle engine are always half the number of cylinders, therefore, in a Packard twin six there are six explosions per revolution and in a six-cylinder Packard there are three explosions per revolution.

3—Putting denatured alcohol or kerosene in the petcocks of the motor when hot will delay the accumulation of carbon materially.

4—The tread of a chassis is the distance between the points of contact of the rear wheels and the ground measured transversely.

5—This is no doubt due to the stiffening of the oil in the gearbox due to cold weather.

6—Yes.

7—It depends upon the temperature outside. You would put more alcohol in if the weather were 10 deg. below zero than you would if the weather were 20 deg. above zero. To keep the mixture from freezing down to zero degrees Fahrenheit, the mixture should consist of 40 per cent denatured alcohol and 60 per cent water.

8—Simply allow it to thaw out, and if it is not damaged due to the freezing all that will be necessary is an extra allowance of oil in starting. If the motor is damaged due to freezing there is no estimating what it may be necessary to do. Sometimes an entire new radiator and motor is required.

Ford Motor Possible for Marine Use

Editor THE AUTOMOBILE:—I am thinking of using a second-hand automobile motor for a motor boat. What kind of a motor would you suggest? How about a Ford?

2—Also, I wish to make some valve seat reamers and would kindly ask that you give me the diameter and angle of seats. Also, the diameter of valve stems of the following makes: Buick, Overland, Reo, Paige, Cadillac, Chalmers, Packard, Ford, Maxwell and Hudson? I imagine that I will be able to use the same reamer for several different makes, using, of course, different stems.

Would appreciate specifications as mentioned above, or any other make of car. The names of cars are those which we work on most. A. M.

Lawrence, Mass.

—The Ford motor can be used very satisfactorily in a motor boat provided that the boat is of light weight and of such a design that a light duty motor will be satisfactory. In a 20-ft. runabout probably a propeller of 18-in. diameter with two blades will be the most satisfactory to use. On this wheel the pits would be about 22 in.

2—The valve diameters and angle of seats and also the diameter of valve stems of the cars you mention are as follows:

Car	Diameter of Seat at Top	Angle of Seat	Diameter of Stem
Overland 83	1 7/8	45 deg.	0.373 + 0.0005
Overland 86	1 1/2	45 deg.	0.372 + 0.0003
Overland 75	1 9/16	30 deg.	0.373 + 0.0005
Maxwell	1 1/2	30 deg.	0.373 — 0.374
Hudson 6-40	1 1/2	45 deg.	0.375
Buick D-44, D-45	*1 1/4	45 deg.	0.3085 — 0.3100
Buick D-54, D-55	*1 1/2	45 deg.	0.3695 — 0.3710
Reo 1912-13 intake	†1 3/4	30 deg.	0.375
Reo 1912-13 exhaust	†1 3/4	45 deg.	0.375
Reo 1914-15-16 inlet	†1 3/4	30 deg.	0.375
Reo 1914-15-16 exhaust	†1 3/4	45 deg.	0.375
Reo 1915-16 six inlet	†1 3/4	30 deg.	0.375
Reo 1915-16 six exhaust	†1 3/4	50 deg.	0.375
Packard Twin Six	1 1/2	45 deg.	0.250
Paige (Continental)	1 11/16	45 deg.	0.3717 — 0.3723
Paige (Rutenber)	1 7/16	45 deg.	0.3095 — 0.311
Ford	....	45 deg.	0.3125
Cadillac	1 3/4	45 deg.	0.370 — 0.371

*At throat. †Widest opening.

Maxwell Motor Same for 1916

Editor THE AUTOMOBILE:—A and B have made a wager and I am stakeholder. A has a 1915 Maxwell, and B has a 1916 Maxwell. A claims that the motor in his car is more powerful, more convenient and has a higher mileage record per gallon of gasoline. Is the 1916 model better than the 1915 model, speaking of the motor?

Battle Creek, Mich. J. J. H.

—The motors of the 1915 and 1916 Maxwell cars are exactly similar.

The History of the American Automobile Industry—17

Development of the Explosion Type Motor—Lebon d'Humbersin Engine of 1801 Was the Father of the Modern Internal Combustion Motor — American Inventors Take Up the Problem

By David Beecroft

IN this third installment of the development of the internal combustion engine the early efforts in America are outlined, four names standing out prominently in this respect. These are: Isnard 1824, Morey 1826, Ericsson 1833, and Brown 1826. From these dates it will be seen that American enterprise did not begin until a quarter of a century after the real start of the internal combustion engine had been developed abroad. It is an interesting retrospect to recall that while the practical advent of the internal combustion automobile in America dates from 1901, the first essentials of this engine were worked out by a Frenchman, Lebon d'Humbersin, in 1801, exactly 100 years earlier. The Lebon d'Humbersin three-cylinder type of motor is illustrated this week.

Early English Patent Laws

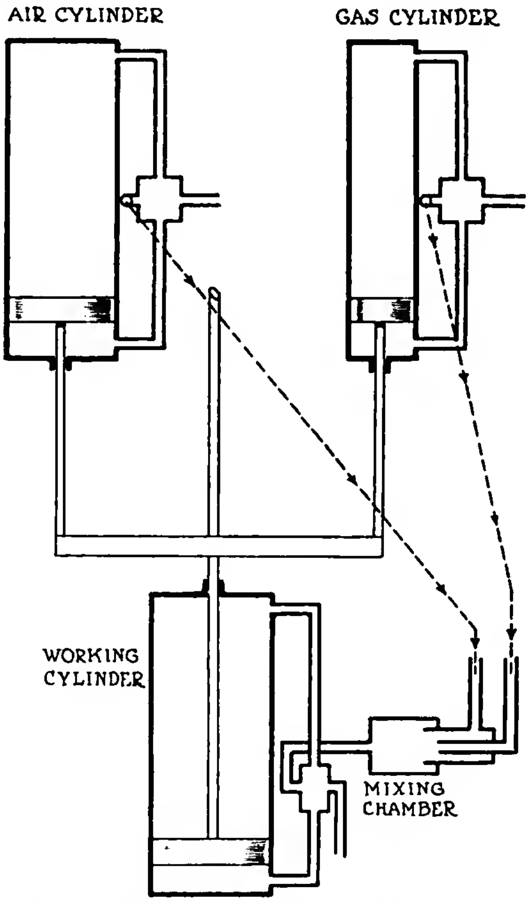
Of course our readers understand that the earlier English patent laws permitted great latitude of description to inventors and that many devices mentioned in a patent may never have been more than ideas. Also that the invention was largely judged from the description rather than confined to the claims, as in United States patents.

Valance Pneumatic Tube System

John Valance, also in England, patented in 1824 a method of travel much faster than any other then known means, viz., the pneumatic tube system. He proposed and described cast-iron tubes 6 ft. in diameter by 12 ft. long, connected by flannel packed joints and having a track inside. He also explained that the power could be furnished by several of the large blowing pumps used for mine ventilation and that doubling the number of pumps would double the speed while such a large car area as proposed would furnish ample thrust even at very low air pressure.

Two More Steam Types

In 1833 Maceroni & Squire, England, built one of the most simple and compact vehicles yet seen, and followed this with another in 1834, one of which afterward went to Paris and the other to Brussels, where they attracted considerable attention. Maceroni continued building steam carriages until as late as 1841.



LEBON D'HUMBERSIN EXPLOSION MOTOR OF 1801

Practically the first explosion type motor was the Lebon d'Humbersin of 1801, which deserves to be classed as the father of the present type of internal combustion motor. This engine was a very close anticipation of the Brayton engine, an American design which figured prominently in the recent Selden patent litigation, and which engine came about 1875, or approximately seventy-five years after the d'Humbersin. The d'Humbersin engine had three cylinders, the two upper ones in the illustration serving for storing air and gas. From these two cylinders the respective air and gas were brought into a mixing chamber and thence into a combustion chamber, where they burned and expanded and were then carried to the working cylinder. This engine, while right in general theory, undoubtedly gave much trouble because of the difficulty of handling and the losses involved in attempting to carry the red hot gases from the combustion chamber through the valves and pipes to the double-acting working piston.

Lebon d'Humbersin's activities in engine development were followed by Sir George Cayley in 1807, who developed a hot-air engine and who in 1837 patented the application of this engine to an automobile. His patents show an engine with two or more cylinders, water-cooling and self-starting so long as the fire was burning.

While these inventors are all foreigners, the same period found American mechanics taking up the problem, as shown by patents to M. Isnard of New York, in December, 1824, and to S. Morey in April, 1826, descriptions of which were lost in a patent office fire. About this latter date John Ericsson, American, began working and in 1833 brought out his hot-air engine, which attracted much attention for the next score of years. This differed somewhat from the Cayley device of 30 years before in that it employed outside heating and, like the Stirling, was dependent upon the durability of the surfaces exposed to the fire. He employed a regenerator or economizer, as it was then called, but instead of passing the air back and forth through this economizer, it had a partition along its central line so that the incoming cool air passed one side of the partition and the outgoing exhaust passed the other side. The heat from the exhaust was carried by the metal through the partition and given up to the incoming cool air on the other side. Like the Cayley device, an air pump was used to force atmospheric air through the economizer and into the head of the working cylinder, which head, being heated, expanded the air in addition to the heat received from the economizer, and drove the working piston, after which the hot air was exhausted as in any steam engine, passing through the economizer on its way out. By the use of the ordinary steam admission valve, the entrance to the working cylinder could be controlled and the air from the air pump cut off at part stroke and used expansively.

Ericsson Used Internal Heating

Probably his most ambitious attempt was a four-cylinder engine installed in an ocean-going steamship at New York, which made several trips with this power. As first made these cylinders were 14 ft. diameter by 8 ft. stroke. Ericsson used external heating and such large volumes of air were impossible to heat quickly. The cylinders were afterward reduced in size and finally the engine was replaced by a steam equipment. Some forms of Ericsson's engines, particularly small ones, with some improvements, were on the market for many years under his name, whereas the Stirling has in recent years been best known as the Rider.

Brown's Combustion Engine

In the same year (1823) that Gurney, England, began his steam carriage work, the internal combustion engine was worked on by Samuel Brown, also an Englishman, whose patents are dated 1823 and 1826. By some, Brown's engine is thought to be an improvement on Cecil's, but it seems rather to have been suggested by Watt's condensing steam engine. He seems to have used atmospheric pressure as his source of power with the air engine exhausting into a vacuum formed by producing a flame in a closed chamber, allowing most of the products to escape and condensing the remainder by a jet of water. Crude as this idea seems to have been, it is said to have been actually used to pump water, drive a boat on the Thames and propel a road vehicle at a reasonably rapid rate of speed.

With this activity in both gas and steam engines it is but natural that compressed air should come in for some attention, and we find a number of inventors working along this line, one of them being William Mann, England, who began work in 1827 and secured a patent in 1829. He advocated using compressed air, which should be compressed by several stages, now recognized as the proper procedure. He also advocated compressions of thirty-two to sixty-four atmospheres (450 to 1000 lb.) and power stations at frequent intervals along the roads. A central station in the colliery districts with the distributing mains along the principal roads, was also advocated by him. At that period tanks of compressed coal gas for lighting purposes were sold much as acetylene is sold at present, and it is likely that his carriage employed these tanks, but filled with compressed air, for the propulsion of his vehicle, built in 1830. About this time a Yankee, Lemuel W. Wright, proposed in connection with compressed air carriages that the air should be heated before using, or used with steam, in order to secure a greater economy. This practice is now quite common where compressed air is used to any considerable extent. At a somewhat later period it was thought to add economy to add compressed and heated air to the steam from boilers and this was quite commonly done.

Compressed Air and Rails

In 1840 A. & T. du Motay, France, applied compressed air to vehicle propulsion, but although designed for road use, the only vehicle constructed ran upon rails. It would carry three passengers, stored the air at about 250 lb. pressure, worked at 50 lb. and its inventors contemplated pressures as high as 900 lb. and heating it before using. They also provided an emergency supply for hill climbing or as a reserve in case the other became exhausted unexpectedly—a provision now commonly fitted in most gasoline tanks.

Another Compressed Air Type

Fifteen years later, 1855, another compressed air carriage was seen upon Paris streets, invented by Mr. Julienne. It weighed about a ton when loaded and carried its air supply at about 400 lb. pressure.

A Twenty-Passenger Vehicle

About 1848 Baron von Rathon ran a 3-ton compressed air vehicle on English roads at 8 to 12 miles per hour, carrying as many as twenty passengers. The air reservoirs were of 75 cu. ft. capacity and filled with air at 750 to 900 lb. pressure. The inventor continued work along this line for 20 or more years. Many other experiments were made with compressed air, but almost wholly without bearing on the solution of the automobile problem, so no further mention need now be made of the compressed air progress.

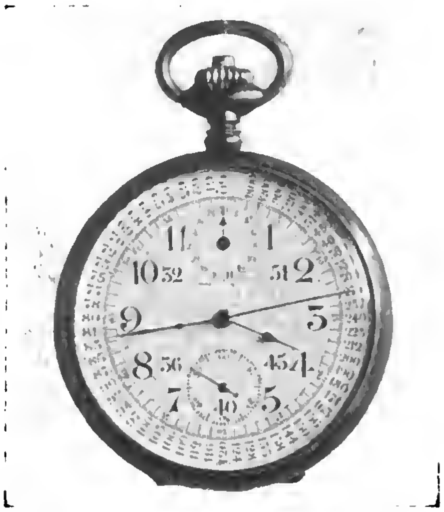
In 1833 L. W. Wright described a non-compression explosion engine working on both sides of the piston, the cylinder being water-jacketed.

ACCESSORIES

Silberberg Master Cronograph

ENGINEERS and manufacturers interested in time and motion studies will find the Master Cronograph of assistance in this work, the instrument having been designed for the purpose. The Cronograph, illustrated herewith, contains a seventeen-jewel timepiece which is extremely accurate, and in addition contains divisions in seconds and fifths for the time study feature. The figures on the outside of the dial designate operations per hour for any operation within 1 min. and the figures on the inside, 51, 45, 40, etc., denote operations per hour for any operation running over 1 min. For instance, if the large black hand were stopped on 13 sec., denoting the completion of an operation, the reading under this hand would show 275, being the number of operations which could be completed in 1 hr. on a basis of one operation taking 13 sec.

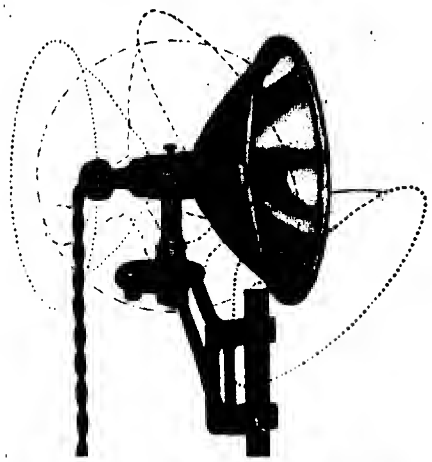
The instrument operates entirely from the crown on the start, stop and fly-back system, the timepiece feature being the same as any modern watch. The works are impervious to magnetism, heat and cold, and are of Swiss manufacture. The case is gun metal.—M. J. Silberberg & Associates, Chicago, Ill.



Silberberg Master Cronograph for use of engineers and manufacturers in motion study work

Kaufman Spot Light

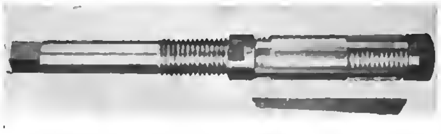
The Kaufman light is provided with a 6-in. reflector and is designed for mounting on the side of the windshield. It is provided with a universal joint which allows moving in any direction and there is a clamp for fastening it in any position desired. It sells for $7.50.—Kaufmann-Williams Lamp Co., Santa Ana, Cal.



Kaufmann light for windshield mounting

Carter Spark Detector

This device is designed for locating a defective spark plug. The plugs are removed from the motor one at a time while the motor continues to operate on the remaining cylinders. The detector is placed against the metal of the plug below the porcelain and the indicator immediately shows whether the plug is operating correctly or not. Price, $1.50.—Carter Spark Plug Detector Co., Detroit, Mich.



Carter detector to locate defective plugs

Malleable Aluminum Alloy

An aluminum alloy which can be die-cast and also sand-cast from which the castings are unusually smooth and free from pin-holes and other surface defects is being put on the market. According to the manufacturers, it is about 25 per cent stronger than ordinary No. 12 aluminum and will stand considerable twisting and bending. The usual drag on tools when it is being machined is noticeably absent and in filing the file is not filled and clogged. A volatile salt in its composition, it is said, gives it these characteristics. It is produced either in castings or pigs, the cost being slightly greater than that of ordinary aluminum alloys.—Pioneer Brass Works, Indianapolis, Ind.

Non-skid truck tire made by the Modern Railway Appliance Co.

Non-Skid Truck Tire

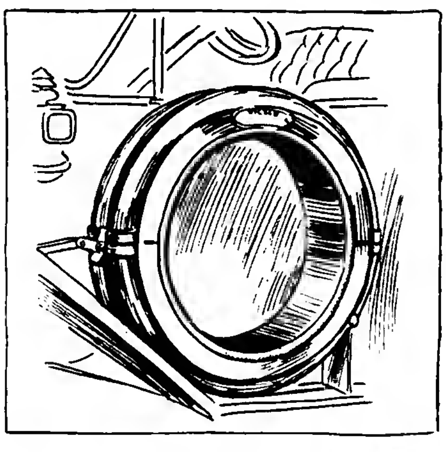
Better traction is said to be obtained by the use of cylindrical rubber blocks held in place by steel forgings. The latter have the same resiliency as the former since they are cushioned with rubber. After the rubber becomes worn, the bolts holding the blocks are loosened and the rubber blocks are turned, giving a new wearing surface. In this way the blocks can be used several times. A 30,000-mile guarantee is given.—Modern Railway Appliance Co., Albany, N. Y.

Victor Tire Holder

This Ford tire holder is made in three sheet steel sections and completely incloses the tires; the holder takes two. The Duplex is another model which is like the Victor except that it incloses only the lower half of the tires. The Simplex is like the Duplex, except that it holds only one tire. The price of the Victor for 30 by 3½ is $10; this does not take demountable rims; the demountable rim type costs $12. The Duplex 31 or 32 by 3½ costs $4.50 and 36, 37, 38 or 40 by 5½, $7. Prices of the Simplex range from $3 to $5.—International Stamping Co., Chicago, Ill.

Wood's Polishing Cream

This cream is designed to preserve the finish and appearance of a car, preventing paint and enamel from checking or cracking. The cream is clean to use and has no bad odor or injurious effect on the hands. A bright, dry, high gloss that does not gum or gather dust can be obtained in from 20 to 30 min. The cream



Victor tire holder, full inclosed type

is put up in 12-oz. bottles in cartons with suitable cloths for application and polishing packed in the top of each carton. A single bottle, if properly used, will keep the finish of a car in the best of condition for a year. The cream is guaranteed on a refund basis. It sells for $1 per bottle by mail to any point in the United States east of Denver, Col.—Wood's Auto Polishing Co., Galesburg, Ill.

Rideover Spring Lubricators

After slightly separating the spring leaves thin strips of Rideover graphite compound are slipped between them, it being unnecessary to disassemble the springs to put them in. When between the leaves the graphite spreads, lubricating the entire contact surface, the compound being designed to stay in place for a long time insuring constant lubrication. The strips are easily handled and sell for $1 per box of sixty.—Avery Portable Light Co., Milwaukee, Wis.

Paco Accelerator for Fords

The throttle of the Ford is actuated by a small pedal which, however, is not attached either to the footboards or to the cylinder head, so that these can be removed without interference. The action of the accelerator is separate from that of the hand throttle. The pedal is so balanced that the weight of the foot is supported, avoiding fatigue when using the accelerator for long periods. The pedal projects through a small opening in the dashboard and connects with the throttle through a steel cable. Price, $1. —Peoria Accessory Co., Peoria, Ill.

Pioneer Searchlight

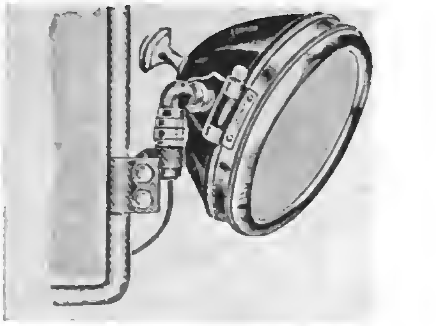
This light clamps to the windshield and may be set at any angle forward or backward, up or down, its motion being practically unrestricted. It is made in three models, the 4½-in. lamp throwing its light 200 ft. and the 7½-in. light 250 ft. The lamps sell for $5.50 and $7.50, respectively, while the 7½ size equipped with a rear view mirror lists at $10.—Pioneer Lamp Co., Chicago, Ill.

Instanto Spark Plug Tester

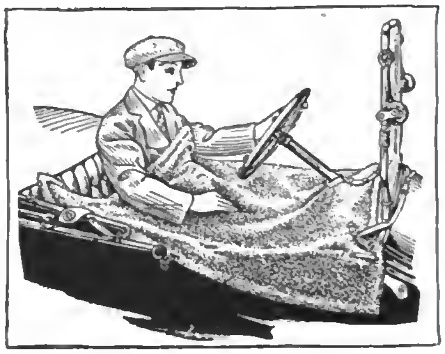
By the use of the Instanto device, a spark plug may be tested without removing it from the motor. The tester, as shown in the illustration, is held so that one point touches the terminal cap, the other contacting with the shell of the plug. If the latter is working correctly a spark appears regularly at the gap between the two points in the tester.—W. Jackson & Co., Chicago, Ill.

Frunt-Seet Robe

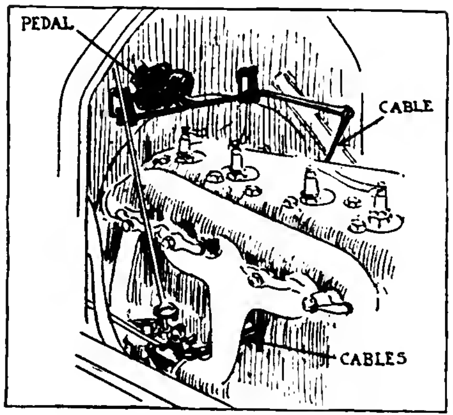
The robe fastens to the side of the body and to the dash and thus keeps the driver warm. A special flap allows it to fit around the steering post. It is made in sizes to fit all cars and comes in black, or green plush, cloth-lined, and is reversible to fit right or left drive. Price, $6.50; rubber, cloth-lined, $5; rubber, khaki-lined, $4.50. Special sizes for Fords finished as above, $5, $4.25 and $3.75 respectively.



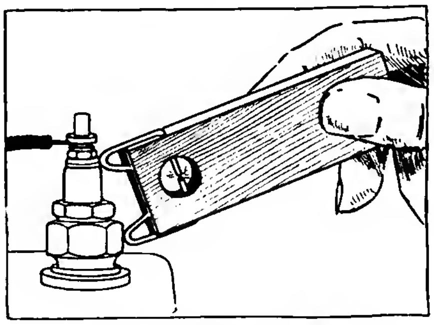
Pioneer searchlight moves in all directions



Frunt-Seet robe for driver's protection



Paco foot accelerator for Fords



Instanto spark plug tester

Special suits for motorists, known as Coverall, are made. They are to protect the clothing and are in one piece. Olive and tan khaki are the colors offered, price, $2.25, $2.75 and $3.25, according to goods.—Automobile Apparel Co., Port Chester, N. Y.

Robbins & Meyers Radiator Ornament

This ornament may be attached to the filler cap of any car and consists of a four-bladed fan which is operated by the air currents caused by the motion of the car. It spins swiftly at the lowest car speeds and the speed of rotation increases rapidly on acceleration. When revolving in the sunshine the highly polished blades produce the effect of a radiant disk. A baked gloss-black enamel finish is applied to the body of the fan and the blades are furnished in nickel or polished-brass finish. The fan weighs about 1 lb. and the diameter of the blades is 4 in. A screw threaded in the base of the fan secures it to the radiator filler cap upon drilling a ¼-in. hole through the latter. If the radiator cap is not shaped conveniently for this mounting a special bracket mounting clamping around the radiator filler tube may be used. With screw in base the fan sells for $1.50.—Robbins & Meyers Co., Springfield, Ohio.

Ona-Moto-Lite Signal

A new device for signaling has been put out under the name of the Ona-Moto-Lite. It works on an arrow indicating principle, giving direction of turning and stop signals. There are no lenses used, the transparent surfaces being red and green glass. The arrow for the left turn is a brilliant green 4½ in. long. The word Stop is a bright red. One of the features is an electric pilot switch which may be placed on the cowl board or other convenient place to show the driver that the signal is operating. It is finished in hard baked glossy black enamel and is placed on the left rear fender or back of the car. The price of the device is $5.—Ona-Moto-Lite Co., Cleveland, Ohio.

2,423,788 Cars and Trucks

ALTHOUGH the increase in the number of automobiles registered in 1915 is 44 per cent higher than the increase shown in 1914 over 1913, there yet remains very large possibilities for increase before the much-discussed saturation point of the country is reached. The error is frequently made of using the total of cars manufactured as the criterion instead of the total registrations in the country. A considerable percentage of automobiles manufactured are exported. This approximated 50,000 for the past year. It will in all probability increase rapidly when normal conditions are restored, when ocean shipping rates are back to normal. America is bound to benefit after the war, in that many of the European countries will not be ready to carry on their export trade as they have done in the past.

The saturation point of the country is yet far off. Take one State, for example. Minnesota has 156,000 farmers. The average farm is 177 acres. The average value per farm is almost $10,000. These farmers have enjoyed two of the most successful years in their career. Of the 156,000 farmers, only 46,000 own automobiles to date. Conservative financial men of that territory say that 100,000 are financially able to own cars. With the present bumper crops and high prices, this number can be increased. To Minnesota add a dozen of the other great agricultural states of the Mississippi Valley. You soon have a total of well over 1,000,000 farmers, located in the most fertile area in the country. These farmers can absorb the entire supply of cars. But when you subtract export figures, and those annually destroyed in wear and tear, you find that the saturation point is not coming so rapidly as many would have you believe. While the saturation point for high-priced cars was looked for a few years ago, it is satisfactory to know that each year sees the boundary of high-price selling zones constantly extended, and at present high-priced cars are being sold in cities and towns where manufacturers thought sales impossible a few years ago. Some of these sales are due to large crops, some to higher livestock prices, others to higher prices for minerals, and others to improved stock prices and general industrial improvements. From year to year varying conditions are going to occur and so with normal advancement the saturation point is being pushed back a little each year and the field of automobile consumption correspondingly extended.

Tractors for Farmers

ONE form of transportation assists another. The more systems of travel, the more travelers and the better the service. The development of trolley systems did not injure railroads, and the automobile has not injured the trolley. Population increases, demands of travel increase, and transportation facilities must increase.

One form of motor power assists another. The automobile is going to hasten the introduction of the agricultural tractor. The automobile has already impressed on hundreds of thousands of farms the utility of the internal combustion motor. The agricultural tractor of to-day is but another adaptation of the automobile motor.

At the start the motor truck was largely an offshoot of the automobile. Later new makers tried to blaze a new highway of truck engineering, but so far as the engine is concerned, the lessons learned in automobile development have applied to trucks. In many other respects the direction of progress in trucks has followed that in automobiles. So may we expect that agricultural tractor development will follow that of automobiles and motor trucks. The reduction of weight is as applicable in one as in the other. The higher motor speeds and lighter motor parts apply equally to automobile, motor truck and agricultural tractor. The inclosing of the driving elements started in the automobile has been taken up in the truck and later will, with equal certainty, be incorporated into the agricultural tractor. The trend of progress in all these is largely alike. Already truck manufacturers are showing commendable judgment in quickly building on the development of the automobile engineer. Those agricultural tractor makers taking advantage of this will succeed, granting that the other aspects of their business are equally capably cared for. Those tractor makers who push aside what the truck and automobile makers have done for them will fail.

Value of Automobile Output Increased 350.3 Per Cent Between 1909 and 1914

Government Statistics Show Value of Output in 1914 Was 181.7 Per Cent Greater Than 5 Years Before—Number of Establishments Increased 0.07 Per Cent

WASHINGTON, D. C., Feb. 17—According to a statement issued by the director of the Bureau of the Census, Department of Commerce, this city, there were in 1914 just 338 establishments manufacturing complete automobiles, their output being 573,114 cars, valued at $465,042,474.

Output Gains 350.3 Per Cent

Comparing the foregoing figures with the 1909 report, the latest issued by the bureau, it is found that though the number of establishments in 1914 has increased only 0.07 per cent during the five years, the number of establishments in 1909 being 315, output, however, showed a large increase—350.3 per cent—the 1909 output being 127,287 cars. The value of the 1914 output was 181.7 per cent greater than that of 1909, which was $165,099,404.

In regard to the 1914 establishments it is stated that thirty-eight of the 338 mentioned were engaged primarily in the manufacture of bodies and parts, agricultural implements, and other products, and reported the manufacture of complete automobiles as a subsidiary product. In addition there were twelve establishments which manufactured twenty cars, either for experimental purposes or for their own use, upon which no market value could be placed.

The fact that the increase in value of the output during the five years was much smaller, relatively, than the increase in number of machines made is accounted for not only by a general reduction in prices, but also by the production of a larger proportion of machines of low-priced makes in the later year as compared with the earlier.

Of the total number of automobiles manufactured during 1914, those operated by gasoline or steam numbered 568,399, and those operated by electricity, 4715, as compared with 123,452 operated by gasoline or steam, and 3835 by electric power, manufactured in 1909. The increase during the five years in the number of gasoline automobile and steam machines manufactured was thus 360.4 per cent, and in the number of electrics, 22.9 per cent.

454,876 Touring Cars

Touring cars were, of course, the principal type manufactured during the two census years. In 1914 the output of this class of vehicle was 454,876, valued at $351,585,518, as compared with 76,189, valued at $113,510,575 in 1909. Of the total production for 1914, the number designed for pleasure or family use was 544,255, compared with 119,190 in 1909. For business purposes and for use as public cabs, omnibuses, ambulances, patrol wagons, fire engines, etc., 24,144 machines were manufactured in 1914, as compared with 4262 in 1909. The output of delivery wagons and trucks was 22,753 in 1914, as compared with 2771 in 1909.

The report also classifies the gasoline and steam automobiles manufactured in 1914 according to their horsepower. The production of vehicles of less than 10 hp. amounted to only 391; of from 10 to 19 hp., to 45,116; of from 20 to 29 hp., to 346,399; of from 30 to 49 hp., to 163,468, and of 50 hp. or more, to 13,025.

These figures do not represent the number of establishments nor the value of products of the entire automobile industry, but only the figures for establishments making complete automobiles.

Comparative statistics of the two years follow:

	1914	1909	Per Cent Increase
Establishments	338	315	.07
Output	573,114	127,287	350.3
Value	$465,042,474	$165,099,404	181.7
No. of Vehicles Made:			
Gasoline and steam*	568,399	123,452	360.4
Family and pleasure	544,255	119,190	356.6
Touring Cars..	454,876	76,189	497.
Value	$351,585,518	$113,510,575	209.
Delivery wagons and trucks	22,753	2,771	721.1
All other	1,391	1,491	6.7†
Electric	4,715	3,835	22.9

*Returns were received from only two establishments making steam automobiles in 1914. The statistics for these companies are consolidated with those manufacturing gasoline automobiles in order to avoid the disclosure of their operations.

†Decrease.

Belden Is Packard Body Engineer

DETROIT, MICH., Feb. 15—E. H. Belden, who has been with the Packard Motor Car Co., for several months, engaged in special research work, has been promoted to body engineer. He is an old-timer in the automobile engineering field.

Goddard Is Dodge Assistant Engineer

DETROIT, MICH., Feb. 15—Chief Engineer Russell Huff of Dodge Bros., has appointed G. E. Goddard assistant chief engineer.

Mr. Goddard recently left the Packard Motor Car Co., where he was body engineer and where, during the six years he was with the engineering department, he worked at various times in most of the different divisions of the department. His stay with Packard was not a continual one. After the first three years he went with the Studebaker Corp., remaining there two years and then returned to the Packard company. Previous to these connections he was for three years chief engineer of the Mora company, Rochester, N. Y.

Crawford and Gunn on Premier Engineering Board

DETROIT, MICH., Feb. 15—The Premier Motor Corp., Indianapolis, Ind., has secured the services of E. G. Gunn, chief engineer of the Northway Motor & Mfg. Co., this city, and C. S. Crawford, chief engineer of the Cole Motor Car Co., Indianapolis. These two men, together with J. L. Yarcan, builder of the Curtiss V-type aviation engine, are to compose the engineering board of the Premier concern.

C. W. Nash, president of the General Motors Co., who is now managing the Northway company, following the resignation of general manager A. F. Knoblock, has made no engineering appointment to fill Mr. Gunn's place.

Page Buggy to Make Front-Wheel-Drive Truck

MARSHALL, MICH., Feb. 9—The Page Buggy Co., which some time ago started to make automobile trailers, will probably also soon start to make a front-wheel-drive truck. It is said that a company having a capital stock of $100,000, the officers and stockholders of which will be largely those of the Page company, is now being formed.

Only Two Scripps-Booth Models

DETROIT, MICH., Feb. 16—The Scripps-Booth Co. has raised the price of its four-cylinder roadster from $775 to $825.

The company also announces that the speedster model shown at the New York and Chicago shows and called the Vitesse is not to be marketed, nor is any form of eight-cylinder roadster to be made. Besides the four, the line will include only one other model, this being an eight-cylinder, four-passenger car selling at $1,175.

44,365 Fords Made in January

DETROIT, MICH., Feb. 12—There were 44,365 cars made by the Ford Motor Co. during the twenty-five working days of January. This is at the rate of better than 1774 cars a day. It is the second largest one month's output of the company, April, 1915, holding the record with 46,510 cars made.

British Imports $37,821,680

Exports for 1915 Still Total Over $12,000,000 or 64% of 1914 Figure

LONDON, ENGLAND, Jan. 26—Automobile import and export statistics just published by the British government are interesting on account of the comparisons they allow between the war and the pre-war periods. For the twelve months ending December, 1915, England has imported a greater number and a greater value of automobiles than in any period of her history. The actual number of complete cars and chassis brought into the country was 20,546, but of these 754 were re-exported, leaving a net import of 19,792. For 1913 the net imports (making the deduction for re-exports) was 12,993; the figure was practically the same for 1912. The value of these imports for the year 1915 is $37,821,680, or $42,065,920 if the re-exported cars are considered. Taking the gross import figures, which includes cars remaining permanently in this country and those re-exported to the colonies or other foreign countries, the increase for the twelve months is 26.29 per cent.

British exports show a loss for the twelve months of 35.69 per cent., the figures dropping from $19,741,715 in 1914 to $12,695,955 in 1915. It is necessary to go back to 1910 to find such a low figure.

The British statistics do not deal with the motor trucks which were thus bought direct by the army authorities in America and elsewhere, and imported by them. They do include those trucks imported by dealers and afterward sold to the government.

The re-export figures are decidedly low, the number of cars and chassis coming into Great Britain for transit to other countries being 754 against 1785 in 1913. This business has dropped back to the position it occupied in 1908. This is explained by the fact that most of the re-exported cars came from France and other Continental countries, and were sent through England in order to get better shipping rates, or because Colonial agencies were held by English firms. This business has been entirely stopped since the outbreak of the war, by reason of all Continental automobile factories being engaged on munitions.

The value of imported parts shows less change than the value of complete cars. This is explained by the fact that while few parts have come from the Continent of Europe, there has been an increase of cheap American cars, such as the Ford, which are brought in a knock-down condition and classed as automobile parts. Since 1913 the authorities differentiate between car parts and tires. Thus in 1913 the value of imported tires was $11,620,775, while in 1915 it had dropped to $7,120,845. If re-exports are included in these figures, the drop is considerably less, for England sent more foreign tires out of the country in 1915 than in 1913. This is doubtless explained by the fact that England received American and French tires and then shipped them to Russia and other countries engaged in the war.

BRITISH AUTOMOBILE IMPORTS

Year	Cars and chassis	Value	Value of parts	Value of cars and parts
1908	6,530	$11,013,110	$7,752,590	$18,769,700
1909	7,747	11,446,570	8,167,335	19,613,905
1910	9,915	13,861,275	9,202,005	23,063,280
1911	11,909	14,902,840	11,661,025	26,563,865
1912	13,164	15,977.580	15,926,135	31,903,715
1913	12,993	15,683,555	17,104,965	32,788,520
1914	12,408	14,714,065	13,167,780	27,881,845
1915	19,792	20,209,690	17,611,990	37,821,680

Re-exports have been deducted from above figures.

BRITISH AUTOMOBILE EXPORTS

Year	Cars and chassis	Value	Value of parts	Value of cars and parts
1908	2,441	$4,383,100	$1,909,695	$6,292,795
1909	2,801	6,188,935	2,629,090	7,818,025

Lee Tire Sales Increase 100 Per Cent

NEW YORK CITY, Feb. 10—Lee Rubber & Tire Co. sales for the month of January of its puncture proof tire increased 100 per cent over the corresponding month in 1915. Sales of the regular pneumatic increased 70 per cent. The output is now 1200 tires a day.

The Lee company reports to the New York Stock Exchange, for the ten months ended Oct. 31, 1915, as follows:

Net Sales	$2,794,025
Cost of sales, including depreciation $51,052	1,991,691
Gross profit	802,333
Profit on materials sold	1,100
Total profits	803,433
Selling, administration and general expenses	364,017
Balance	439,416
Other income	18,498
Total income	457,914
Charges	14,439
Surplus	443,475

Hall Motors, Ltd., to Build Canadian Motor Trucks

TORONTO, ONT., Feb. 11—Hall Motors, Limited, will manufacture purely Canadian trucks. A plant has been secured at Markham, which will be fully equipped with every modern facility. During the current year it is estimated that the output will be between 400 and 500 trucks. E. A. Hall, carbureter and motor expert, under whose management the plant will be conducted, states that quality will be the watch-word of the new industry. Production will begin in March.

Continental 100% Dividend

Capital Increase to $5,900,000—46,000 Motors Produced in 1915—125,000 in 1916

DETROIT, MICH., Feb. 15—At a special meeting of the directors of the Continental Motor Mfg. Co., they recommended that the stockholders approve at a meeting to be held to-morrow, that a stock dividend of 100 per cent be declared; that the capital stock of the company be increased from $2,900,000 to $5,900,000, and that the par value of the shares, which is now $100, be lowered to $10. It is more than likely that these suggestions will be approved.

Under the new plan of reducing the par value of the share, the holder of one share of present common stock will receive ten shares of the new stock and in addition ten shares as his stock dividend.

This is the second 100 per cent stock dividend the Continental company will have declared within the last four months.

Production during 1915 was more than 46,000 motors. For 1916 the company expects to make 125,000 or more, half here and the other half in the plant in Muskegon. Within the next three weeks the average daily output is expected to reach 300 motors at both plants. The total number of men on the pay roll will be about 6000.

Genemotor Price Raised $10

NEW YORK CITY, Feb. 14—In line with the present high cost of materials and the corresponding prediction of higher prices, the General Electric Co. has followed the lead of a few of the automobile makers by advancing its retail price of the Genemotor lighting and starting systems $10 to $85. This change applies to the 1916 shaft drive type.

Coincident with the change in price it is announced that the General Electric Co. has taken out a license to produce the Genemotor under the Coleman starter patents, Nos. 745,157 and 842,827. These patents were declared valid in the Court of Appeals last December after two years of litigation in the local courts.

Surre Continental Rubber Second V.-P.

ERIE, PA., Feb. 11—W. J. Surre, manager of the tire sales department of the Continental Rubber Works, this city, has been elected second vice-president.

Coburn Is Maxwell Advertising Manager

DETROIT, MICH., Feb. 16—Andrew E. Coburn, former advertising manager of the Cleveland Twist Drill Co., has been appointed advertising manager of the Maxwell Motor Co., this city.

Perlman Rim Patents Declared Valid and Infringed in Court of Appeals

Decision of Lower Court Upheld in Suit of Demountable Rim Inventor Against the Standard Welding Co.—History of the Development of Perlman's Invention

NEW YORK CITY, Feb. 15—The United States Circuit Court of Appeals, Second Circuit, has handed down a decision affirming the decision of Justice Hunt, C. J., in the United States District Court, declaring the Perlman demountable rim patent valid and infringed by the Standard Welding Co. of Cleveland, Ohio. An injunction and accounting order against this company was issued last August by the lower court.

The Perlman demountable rim patent case is of more than ordinary interest because it affects the use of demountable rims on nearly all the automobiles made and now in service in this country.

The Perlman demountable rim patents were applied for in 1906, and the patent was finally granted after many years of delay in the Patent Office, on Feb. 4, 1913. Perlman, however, was not behind these delays, for both he and his attorneys were insistent upon a prompt issue of the patent, because tire and rim makers and automobile manufacturers knew of his invention and had boldly appropriated it, pending the issue of his patent.

700,000 Cars Will Use Them

Good judges of the volume of the output of the automobile industry estimate that of the 1,000,000 cars produced during the current year about 700,000 will use demountable rims, and yet the royalty for the use of these rims, as asked for by Mr. Perlman, will be so moderate that it will not add at all to the retail selling price of automobiles. This statement should quiet any apprehension that might be felt regarding any added cost owing to this decision.

The testimony in the lower court showed that in 1903 Perlman completed, and in 1904, in a successful way operated his invention on a Royal car, and that for years, beginning away back in 1900, Perlman was industriously at work upon the repairing of tires, always with a view of inventing means to avoid the relays incident to repairing tires on the road.

Completion of the Device

Later on, in October, 1904, he put his wheels on a Welch car, and then Perlman realized that his methods of mounting the demountable rim and the short stem lug used for securing the tire on the rim, were perfect and complete. Later on in the same month he drove this Welch car to the first Vanderbilt cup race on Long Island.

It is well known that a few foreign and American patents were issued for demountable rims held tight upon their wheel bodies by conical and taper fit or bolts pulling the rim down against the wheel body. Perlman's idea was just the reverse; he, while holding the rim rigidly in place on the wheel, separated them by wedges.

Perlman filed his first patent application May 21, 1906, and on June 29 of the same year he filed a continuation and substitute for it, with some additional details. The idea being to patent, as he then said, "A wheel whose demountable rim is bodily detachable from its fixed rim and felly, means being provided for firmly and rigidly retaining the demountable rim on the fixed rim and felly while is use, such means at the same time being adapted to be manipulated for enabling ready, rapid and easy removal of the demountable rim when desired."

Demountable Rims Abroad

Demountable rims were used abroad on racing cars late in 1906 in the Grand Prix Race, but the difficulty with the styles then used lay in demounting the tire rim from the wheel, the two beveled and inclined faces of the rom and wheel were forced tightly together, and use and rust added to this perplexity.

But these other and older kinds of foreign racing demountable rims were of little use, as shown by Joe Tracey and Camille Jenatzy and others who used them in the 1906 Vanderbilt road races, owing to the fact that the rims became so attached to the wheel bodies that it required much more labor to remove them than to take the tire from the rim in the old way in the days of the common, clincher-type fixed tire rim. The device of Perlman was a practical solution of the problem of replacing a deflated automobile tire in a quick and easy way.

The Idea Develops

Perlman's conception of the demountable rim was really a road inspiration. For years he had been working on pneumatic tires, always with a view to their ready replacement and repair on the road, and his first efforts were confined to the production of tools for replacing and repairing tires, but these ideas he found were merely petty time savers, and the tire repair was still always a road job. One day he was out riding with a friend. They had, of course, the usual punctures which were common in those days, and after they had made a roadside repair of the inner tube, Perlman started to pump up the tire, using the primitive hand pump of the period. While engaged in this work and perspiring under the task he suddenly realized for the first time that all his previous ideas were wrong; what was wanted was a removable rim idea, so that the tire could be put on the rim in the garage or barn, inflated there, and carried on the car as a separate unit just as is done today, and then his only problem was to conceive mechanical ways and means for carrying out the idea practically. This he accomplished after exhaustive, costly, laborious, experimental work, finally adopting the wedge and screw, and the air space between the two rims which prevented the rims from rusting together.

Elements of the Invention

Perlman had already solved the problem by his invention of the separating wedge, the bolt and the nut and the use of the short stem lug and the air space between the rims. Simple enough after it was conceived, and anybody can do it now, but nobody ever did it before Perlman did it, although the history of the demountable rim shows that for more than a decade prior to the Perlman invention, many men had sought to discover an efficient means which could positively and effectively retain the demountable rim in place and present displacement thereof, and at the same time permit quick and easy removal of the rim.

Cornell to Address Indiana S. A. E.

CLEVELAND, OHIO, Feb. 11—F. A. Cornell of the Perfection Spring Service Co., this city, will present a paper at the monthly meeting of the Indiana Section of Automobile Engineers Feb. 25, the subject being "Anticipating Complaints."

Harroun Secures Quarters

DETROIT, MICH., Feb. 15—Ray Harroun, the former chief engineer of the Maxwell Motor Co., who is to build aeroplane motors and a special racing car, has leased part of the Dodge Power Building, Jefferson and Brush Streets, where he will start manufacturing and maintain his offices.

Thirty-Five Per Cent Co. Petitions

NEW YORK CITY, Feb. 16—The Thirty-Five Per Cent Automobile Supply Co., 148 Duane Street, has filed schedules showing liabilities of $83,766 and assets of $40,509.

Ford Plant for Calgary

CALGARY, ALTA., Feb. 11—The Ford Motor Co. will build an assembling plant at Calgary, Alta., next spring. The building will be four stories high, with provision made for increasing the size later. They will employ 150 men.

Columbia Motors Co. Organized

Bayerline-Daly Concern To Build 2500 Sixes at $900 in 1916

DETROIT, MICH., Feb. 16—The new automobile company, which former president J. G. Bayerline and former sales manager W. L. Daly of the King Motor Car Co. launched a few weeks ago, will be known as the Columbia Motors Co. In addition to Bayerline, who is general manager, and Daly, who is vice-president and in charge of sales, other members of the new organization are: A. T. O'Connor, secretary, who was formerly with the Olds, Packard and Abbott companies; F. A. Bollinger, factory manager, who was formerly in the same capacity with the King company; Ray Long, engineer, formerly assistant engineer of the Saxon Motor Co.; John Molerhardt, superintendent, who was also formerly with King. W. E. Metzger, well known in automobile circles, is one of the directors.

It is stated that all of the capital stock has been subscribed and an option on a plant in Detroit has been secured. The first demonstrators of the new car, which is a six, to sell at about $900, will be out about March 1, and dealers' cars are expected to be out by June 1. The output for the first year will be 2500 cars.

Only 19 Automobiles Imported During November, 1915

WASHINGTON, D. C., Feb. 11—Supplementing the November export report in THE AUTOMOBILE for Feb. 3, is the announcement that imports for that month amounted to $33,780, and numbered nineteen cars, compared with $81,647 and sixty-two for the corresponding month in 1914. For the eleven months ending November, automobile imports amounted to $312,256, and numbered 204, as compared with $454,733 and 280 cars in the corresponding period in 1914.

Burke Rejoins Gray & Davis

BOSTON, MASS., Feb. 14—W. W. Burke has rejoined Gray & Davis, Inc. He will assume his former duties in connection with the sales department.

24,000 War Trucks Shipped

U. S. Government Could Get 6200 Trucks in About 30 Days

WASHINGTON, D. C., Feb. 12—It has been ascertained by the War Dept. that in the period between August, 1914, and December, 1915, about 24,000 commercial trucks, valued at $64,250,000 were exported for use by foreign armies.

It is stated by army officers that army quartermasters now are giving much attention to the equipment of army field and divisional trains. The view is expressed that the field trains that accompany troops should be animal-drawn, but that for divisional trains, supply, ammunition and sanitary trains motor trucks should be used.

With that end in view, a canvass has been made as to the resources of the country in that particular. The reports to the quartermaster general by manufacturers of trucks show that in thirty days 6200 trucks could be furnished.

Kansas City's Trade Territory Has a Total Wealth of $772,380,183

1916 Is Looked Upon as Its $500,000,000 Year—Production of Crops, Livestock, Zinc Lead and Oil Estimated as Reaching That Total

KANSAS CITY, MO., Feb. 12—It isn't possible to lump Kansas City and its trade territory into a single word this year. At other times the one thing, "crops," might have sufficed to cover all the resources of this big district, including, as it does, western Missouri, Kansas, northwestern Arkansas, Oklahoma and parts of Texas and Nebraska. But this year its description must be more diversified.

The Kansas City trade territory looks upon this as its half-billion year. The production of farm crops, livestock, zinc and lead, and oil—the chief factors—in the adjacent States reached approximately that sum for the year 1915. Of course, all of it does not represent profit and it is not money that will be expended entirely outside of living and other actual expenses. It does not include the value of the manufactured and jobbing products of such cities as Kansas City, St. Joseph, Springfield, Topeka, Wichita, Hutchinson, Oklahoma City, McAlester and others in the Southwest that count Kansas City as their gateway and have resources not dependent upon any of these things.

Farmers, Oil Men and Miners

The sum does represent, however, the returns to the three large classes of producers in this territory—the farmer, the oil man, and the miner. This much money came into their hands as the result of the business of 1915—it is the value of the raw products originating in those States covered by the Kansas City distributing agencies. Some of this money will be used for paying off mortgages, some to buy flour, meat and groceries, and some to pay labor bills, but that amount went into the Kansas City territory last year and is available for one purpose or another.

Nearly an $800,000,000 Field

Itemizing the various components, eight separate items must be listed to make up the wealth of this territory. They reach the sum of $772,380,183 and were compiled from reports of State and federal officials, showing totals for Jan. 1. The tabulation gives details.

The visitor to the annual automobile show that closed to-day in the Case Building—the largest, by the way, ever held in Kansas City—became impressed quickly with the numerous factors tending to make up the immense buying capacity of this territory. At one booth would be a Missouri zinc miner who is selling his ore this year at $110 a ton whereas a year ago he was getting not to exceed $50, at another would be an Oklahoma oil man who had watched the price of his product jump from 40 cents a barrel to $1.30 within the last six months, and at a third would be a Kansas farmer who had paid off the mortgages on his farm out of the tremendous wheat yield of a year ago and now counted the surplus from his last crops as so much free money to go into the banks or be spent for automobiles, talking machines, etc.

Wealth of Kansas City's Territory

Wheat	$142,330,000
Corn	194,740,000
Oats	35,408,000
Hay	43,672,000
Other crops	75,000,000
Livestock (marketed)	198,191,533
Oil and Gas	55,000,000
Lead and Zinc	28,038,650

But that is not all. There is yet the Missouri farmer to be reckoned with who increased the value of his farm output in 1915 to approximately $219,000,000, the Kansas livestock grower who added $49,000,000 to the value of his livestock last year and, likewise, those men from the country districts who have been shipping every week $1,000,000 worth of horses and mules into the Kansas City market for re-shipment to the warring nations of Europe. Like other sections of the United States, this territory has a greater spending capacity than at any other year in its history. As a witness, the cashier of the Kansas City federal reserve bank is introduced. He said:

"The financial resources of this territory are from 15 to 18 per cent above what they were this time a year ago. Then we thought we were the most prosperous section of the country. Certainly we are to-day."

$41,000,000 for Cars, etc.

Figures for the motor car purchases from the Kansas City distributing and retail agencies in 1915 show a total of $41,000,000 for cars and accessories. They are supplied by E. E. Peake, secretary of the Kansas City Automobile Dealers' Assn., and carry with them a prediction that the 1916 sales will closely approach $50,000,000 of which a fifth will be for tires and accessories.

The number of cars owned in the Kansas City trade territory has shown a steady growth under the stimulus of better cars and more vigorous campaigning by the agencies. Missouri has jumped from 16,387 cars in 1911 to 76,462 for the calendar year of 1915 according to the report of the Secretary of State.

The Kansas growth has been practically the same until now it has reached 74,956 registered cars. Two-thirds of these are owned on the farms and in towns having a population of less than 2500 according to an estimate made by the state secretary.

Oklahoma began registering cars last June and on Feb. 2 had 25,029 passenger cars and trucks registered, owned largely in the smaller cities and country districts.

Huge Crop Resources

To explain the resources of this distributing territory it is necessary to go into detailed figures. The field crops of Kansas as a whole for 1915 were valued at almost exactly $250,000,000, a loss over the 1914 totals of $28,500,000. Wet weather during the summer months cut the wheat yield to practically half of that of the 1914 bumper crop of 181,000,000 bushels. But the farmer, the man who grew the wheat and the man who purchases motor cars to drive back and forth from town, sold his 95,000,000 bushels in 1915 at higher prices. The year before, pressed with debts hanging over from previous lean years, he had to sell at threshing time for prices ranging from 60 to 70 cents. He paid off those debts and when the 1915 harvest came around he decided to hold his crops until late for larger prices. He got them, ranging from 90 cents to $1.10 per bushel, by not selling until November, December and January. Now Kansas is selling wheat in quantities never before recorded in the winter months. And the debts he must pay with that money are few. He will spend it largely for luxuries.

Crop Conditions Similar

Crop conditions in the three States, Missouri, Kansas and Oklahoma were very similar. Wheat production was less than the year before in each. Missouri fell 25 per cent behind, Kansas 50 per cent and Oklahoma 25 per cent.

Corn production was greater, totalling for the three States $263,000,000, an increase of $56,000,000 over the preceding year, thus wiping out a lot of the wheat decrease, which totalled $78,000,000 for the three States.

Hay, dairy, poultry and horticultural products showed an increase in all the States, so much so that the totals make 1915 the second largest crop year in the Kansas City territory this century. The 1914 crops were the only ones larger.

Kansas, Oklahoma, and Missouri at this time have the heaviest bank deposits in their history. Kansas banks have deposits of $224,110,565, an increase of $23,000,000 in a year; Oklahoma has $134,476,292, or about $19,000,000 ahead of 1914 and in Missouri the same ratio is maintained, although exact figures are lacking. As an indication of the same growth Kansas City is pointing proudly to its bank clearings and deposits. The deposits on Dec. 31, 1915, in Kansas City banks alone totalled $180,000,000, a gain of $34,000,000 in a year, and the bank clearings for the year reached the total of $3,835,000,000, a gain of $250,000,000 over 1914.

$600 to $900 Cars Favorites

The Kansas farmer is the heavy buyer of motor cars and the average car sold there is the all-purpose car averaging from $600 to $900. The car used in that State must be one that the farmer can drive to town and utilize in bringing back supplies and provisions; in other words, one that isn't so costly that it demands care and washing. Figures taken from the State assessor's lists but not including all the machines owned in Kansas shows Fords to constitute a third of those in Kansas. Buick and Overland come second and third. The list by makes furnished from the assessor's report is:

Auburn	652
Buick	5,998
Cadillac	855
Chalmers	732
Dodge	551
E. M. F.	699
Ford	25,254
Hudson	879
Hupmobile	755
Jackson	512
Maxwell	3,026
Mitchell	707
Oakland	720
Overland	5,515
Regal	523
Reo	2,389
Saxon	378
Studebaker	3,427
Velie	406

Kansas, also, has not yet started actually to build good roads. Any number of counties have enthusiastic plans for highway improvements but few indeed are those that have borne fruit. This is another factor in the sale of cars in that State. Higher-priced motor cars are not purchased when they have to be driven through mud and slush. Road sentiment has crystallized largely throughout the past year, more so than during other years, and it is reasonable to believe many roads that are now impassable in winter will be macadamed or improved before another twelve-month period has passed.

The sale of cars is nearly equally divided between city and country. Kansas City has 9309, St. Louis has 16,000. The western half of the State, Kansas City territory, contains within it Springfield, Joplin, Carthage, Sedalia, St. Joseph, Webb City, and several other cities in excess of 10,000 population. St. Joseph is as large as any city in Kansas and, of course, there are none to compare in size with Kansas City.

High Prices No Drawback

Electrics are sold freely in all of the cities of Missouri mentioned and in each of them gasoline cars selling up to $2,500 and $3,000 and even higher may be found. The hills of Kansas City are no bar to electrics and one big bakery here recently installed a fleet of twenty-two electric trucks. Joplin has recently opened a public charging station and under the stimulus of the war-time zinc prices the Joplin-Webb City-Carthage buyers no doubt will invest more in electrics and the larger and more costly gasoline passenger cars.

Good progress has been made in the last year in increased distribution of electric cars in the Kansas City territory. Kansas City alone has to-day between 800 and 850 electric passenger cars. The city of St. Louis has approximately 750, but must not be classed in the Kansas territory. For the past six months the sale of electric passenger cars has increased very perceptibly and has been stimulated by the high price of crude oil in the Oklahoma territory and zinc war prices in western Missouri. In the Oklahoma oil territory electrics are becoming relatively common. Manager Clark of the Detroit Electric in Kansas City states that there were sixteen recent sales made in Tulsa, Okla., which is the center of the oil section, three in Bartlesville, which is also in the oil district, and three in Muskogee, another oil center.

During the past few months there has been a wider distribution of electrics and as a result of this the business has more than doubled as compared with a year ago. It is now becoming more general to establish some kind of dealer in all towns of 10,000 population or over and to carry demonstrators in them.

Electric Business Doubles

The influence of general improved conditions in the Kansas territory is reflected in the greater sale of electrics. Joplin, Mo., of zinc fame, has eight electrics. In several towns in Kansas the electric is making headway. Topeka, the capital, is not a leading city, but has four. In Hutchinson there are three. Wichita has proved a particularly good second-hand market, one distributor having sold eleven in the past fall.

In Kansas City there are three electric garages, one operated by the Detroit Electric Car Co., a second by Baker R. and L., and a third by a party not selling cars. Of these 800 electric cars in Kansas City all except 250 are kept in the private garages of the owners. The introduction of a new type of rotary converter for charging purposes, which is very simple to operate, is advanced as one reason for a wider use of electrics in Kansas City.

Such oil centers in Oklahoma as Tulsa, Bartlesville and Muskogee are buying more high-priced cars and electrics than ever before. Oil has made many millionaires within the last six months and development is going on so rapidly that extensive new wells undoubtedly will be brought in. This has come about as a result of the price increase since Aug. 1. At that time crude oil at the wells was selling for 40 cents a barrel and production dropped to a low minimum. Then it began climbing and in twenty days had jumped 25 cents a barrel. At that time it was estimated that a 15-cent increase meant that $50,000 more per day was being brought into the Oklahoma fields. Late in January the last advance brought the price up to $1.30 a barrel, an increase from the low mark of last July that means at least $300,000 more per day going into the Oklahoma fields than was at this time a year ago. That money will go largely into the purchase of motor cars.

Zinc and Lead Output

The zinc and lead mines are not confined entirely to Missouri. A fringe of Kansas counties near Joplin and Webb City has several good producing mines and the mineral belt extends into northern Oklahoma. Production in the Missouri-Kansas-Oklahoma fields went up tremendously last year, totalling $26,000,000, more than double that of the previous year, and estimates based on the present prices and production fix this year's total at $38,000,000.

20,000 See Kansas City's First Tractor Show

KANSAS CITY, MO., Feb. 12—The close of the first tractor show here to-day brought statements from the officers of the Kansas City Tractor Club that paid admissions for the week totalled 20,000, a large majority of whom were farmers who came to Kansas City not from curiosity but from a desire to purchase tractors. Sales were heavy, one firm having contracted more than one hundred machines, another seventy-five, and others from twenty-five to fifty.

A Business Crowd

The attendance was unusual. It was a business crowd. Sightseers composed a very small part of it. The show's location in a tent near the Union Station, the cold weather, and the damp ground made it unattractive to the merely curious. Those who went through the gate were there because they had some good reason —farmers and ranchers desirous of investigation, automobile and implement dealers who wished to take on agencies, and tractor owners who came to see the improvements that had been made since they purchased.

Many of the country motor dealers who were in Kansas City on account of the motor show, held in another place, visited the tractor show and some were appointed agents in their respective territories. Tractor manufacturers who also sold motor cars and accessories appointed a large number of their representatives out of the motor dealers. Old line implement houses that have tractors as a part of their farm machinery did not reach this trade heavily. They seemed content to place their agencies with the implement and hardware men in the various county seats. Motor dealers, however, displayed much enthusiasm at the tractor show and many left Kansas City with agency contracts signed up for both pleasure cars and tractors.

Army Tests Artillery Tractors

LAWTON, OKLA., Feb. 12—The use of tractors for hauling heavy field artillery is being tested by a board of army officers at Fort Sill, near here. The board is composed of Colonel Adams, Captain Bryden, Lieutenant McGlachlin. The tests will continue several days and only preliminary results have been announced. These are to the effect that the tractors show a big advantage over horses in the crossing of railroad bridges with the cannon. This is impossible with horses.

The trucks used at Fort Sill, however, have not yet been pronounced a success but the army officers are agreed that the tractors meet all the requirements for motive power for the maneuvering of big guns.

Plan Empire Fair for 1917

LONDON, ENGLAND, Feb. 3—Plans are being made for a British Empire Fair to be held next year. An exhibition building which, it is said, will be the largest of the kind in the world, will be erected at Willesden Green, in the spring of 1917. A new building will be erected and will be designed to provide accommodation for exhibits from almost every known industry. It will continue three weeks.

Richey with J. Walter Thompson

ANDERSON, IND., Feb. 14—S. Hunter Richey, formerly manager of the local branch of the Russell M. Seeds Co. advertising agency, has resigned, and joined the staff of the J. Walter Thompson Co., New York City.

Bates Tractor Business Gains 400%

LANSING, MICH., Feb. 9—According to M. F. Bates, secretary of the Bates Tractor Co., business in January was 400 per cent ahead of that of the first month in 1915.

K. C. Show Attendance 125,000

This Territory Will Handle Large Volume of Cars This Year—Dealers Optimistic

KANSAS CITY, MO., Feb. 12—The motor show closed here to-night with a final attendance that brought the total for the week to practically 125,000, not including the pass admissions to exhibitors, dealers and press representatives. All exhibitors will be rebated for their space and the surplus left in the treasury of the Kansas City Automobile Dealers' Assn. will be spent on good roads promotion in the territory adjacent to this city.

Both attendance and sales were largely in excess of that of any previous show here and almost without exception the exhibitors spoke of expected sales increases for this year of from 20 to 30 per cent.

Business Is Promising

The results of the show go to prove that this territory will handle a tremendous volume of cars this year. The Buick allotment, largely contracted already, is 5000 cars; Overland will handle 6500 machines in the territory that took 3900 last year; Reo and Grant, handled by the same company over a large section, have contracted about 5000, and Oakland expects to increase largely over 1915. Truck exhibitors likewise were extremely optimistic of the show results, saying almost without exception that the actual sales during show week and the prospects obtained exceeded former weeks.

The older pleasure car agents in this territory contracted few new dealers during the show. Their organization has been pretty well worked up through other years but a tendency was shown to cut down the districts alloted to each dealer, making the district smaller so each dealer would go through it more thoroughly. Many of the manufacturers that had not been well represented in Kansas City have appointed new distributors here or taken over the agency as factory branches and these companies, of course, appointed a large number of new dealers. One firm announced it had practically tripled its representation during the six days of the exhibition.

St. Louis Chevrolet Receives $4,000,000 Body Order

ST. LOUIS, MO., Feb. 11—Russell E. Gardner, president of the Chevrolet Motor Co., this city, received yesterday a contract from the Chevrolet Motor Co. of New York for the manufacture and delivery of 200,000 bodies to be built in one year and costing approximately $4,000,000.

The order will necessitate the erection of several additional buildings and the purchase of much equipment. The plant at Second and Rutger Streets, which now produces twenty-five Chevrolets a day, will be increased so that in thirty days the production will be seventy-five cars a day.

Novel Service Plan Inaugurated by Studebaker

DETROIT, MICH., Feb. 11—Studebaker owners in Detroit who spend their evenings at theaters, clubs, hotels, or lodges need not worry any more about the cars they leave standing outside. A novel extension of the service plan of the Studebaker Detroit retail branch provides for nightly inspection of every Studebaker car in the downtown district.

Twice every night a Studebaker service wagon, fitted out with all sorts of equipment, makes the rounds of Studebaker cars, while the owners are indoors. Those to which any form of service is administered are tagged a card specifying just what was done. Service given is without charge to the owner. The service car operates on a regular schedule and it takes about 2 hr. to make the trip.

If the motor is hard to start, as on a cold night, it is warmed up. If the tires are low, they are either inflated, or in case of a puncture, a new inner tube is put in and the owner is notified to call for his old tube. If lights are weak, the bulbs are replaced, or if necessary, the batteries are changed and the owner is instructed to call for his own next day.

If the motor is missing, new spark plugs are put in and the engine is tuned up generally. If snow or rain started to fall after the owner left his car and the top is down, the service crew raise it. If the gasoline supply is too low, 1 gal. is put in the tank.

Dallas Automobile Dealers to Form Common Defense

DALLAS, TEX., Feb. 11.—Dallas automobile dealers representing factories as distributors over the State of Texas are expecting to meet and form a common defense against the views of Attorney General B. F. Looney on their system of arranging selling contracts in which he charges they violate the Texas Anti-Trust Law.

This belief was freely expressed in Dallas to-day following the filing of another suit against the Hupmobile company at Austin late Tuesday afternoon, and the filing of similar suits two weeks ago against the Houston Motor Car Co. of Houston and the Munger Automobile Co.

Automobile men in Dallas to-day declared emphatically that the automobile industry of Texas centered at Dallas, and, representing the investment of millions of dollars, would be destroyed unless the views of the Attorney General are not changed and he does not pursue some other course. It is also predicted unless something is done that many of the big companies would leave the State instead of building their factories and assembling plants in Texas. At the present time local dealers declare that business is blocked and no contracts are being made. Dallas dealers declare they have agents who work in a prescribed territory, and that contracts can hardly be made otherwise.

Late Wednesday afternoon advices were received in Dallas that the Attorney General had also filed suit against the Studebaker Corp. and the Willys-Overland Automobile Co. This action came a big surprise in Dallas. Both companies had planned to establish branch factories in Dallas. This may alter their plans, as under the present work of the Attorney General automobile men declare that the automobile industry in Texas is doomed. The action of the Attorney General has come to Dallas dealers like a thunderbolt.

U. S. Government Truck Bids Open March 6

WASHINGTON, D. C., Feb. 12—The Secretary of the Treasury, through the general supply committee, has sent out an invitation to gasoline and electric motor truck makers and dealers to submit bids, on March 6, for furnishing the executive departments and independent government establishments in Washington with a quantity of trucks during the next fiscal year, beginning July 1. The gasoline trucks will have a capacity of 1000 lb., 1500 lb., 2000 lb., 3000 lb., 2 tons and 3 tons. The electrics will have the same capacity. Rigid specifications have been drawn for the above mentioned trucks, and bidders will be required to strictly abide by them.

Kleiber Truck to Double Plant

SAN FRANCISCO, Feb. 10—The motor truck industry in California is steadily improving and as a result the business of the Kleiber Truck Co. of San Francisco, builders of the Kleiber truck, has increased to such proportions that the local concern has been forced to seek larger quarters. The factory has purchased a piece of land at Eleventh and Folsom Streets covering an area of 205 ft. on Folsom and 275 ft. on Eleventh Street and will immediately start the erection of a one-story fireproof structure that will enable it to more than double its present output.

The Kleiber company is a local stock corporation headed by N. Kleiber with A. Hammersmith as general manager.

Toledo Show Sales Large

Dealers Estimate Demand of 22,100 Cars Up to July

TOLEDO, OHIO, Feb. 12—The eighth annual Toledo automobile show which closed to-night, was, moderately speaking, at least 100 per cent better from every point of view than any of its predecessors.

Sales as reported by the exhibitors were from 75 to 300 per cent better than in 1915. Retail sales especially were far ahead of what had been done at last year's show and this is directly due to the very large number of farmers and others from the rural districts who came from all over the State and from other States.

It is conservative to estimate that the number of cars which the dealers expect to dispose of by the end of the 1916 selling season, which means next July, is 22,100. This to make it clearer, refers to the total sales of 1916 cars, from the beginning of the season or the middle of 1915.

Out of the 22,100 cars which are expected to be sold 17,100 are credited to eight concerns or distributors, which leaves a total of 7000 to be sold by the other thirty or thirty-five dealers with headquarters here. All told about seventy different makes of passenger and commercial cars are handled in the city.

Agents' Territory Varies

The size of the territory of the local agents varies a great deal. The Blevins Auto Sales Co., for instance, which handles the Studebaker, has nearly all of Ohio, all of West Virginia and Kentucky, part of Michigan, Virginia and Indiana. It is the biggest of all Studebaker distributors and expects to dispose of 5000 cars this season. The Dodge agent, H. W. Lancashire, has only five counties within which to sell the 500 cars he has thus far contracted for. The Maxwell and Jeffery distributor, the Landman-Griffith Co., has twenty-two counties of Ohio and expects to dispose of 2000 or more cars. The Roberts-Toledo Co., Ford agent, has contracted for 4000 cars and has seven counties to sell them.

It is hardly necessary to give some reasons why the local agents expect to sell on an average more then 100 per cent more cars during the season. In their territory just like in that handled by the Cleveland dealers, or the Detroit agents, or those from Minneapolis, or Buffalo, every line of business, every industrial concern, every bank, every farmer, has been doing greater business, has been making more money. There is no such thing as pointing out merely to one or two or half a dozen particular products, whether of the farm or from the factory, which have or are causing this increased automobile business. As H. W. Blevins, the Studebaker distributor, says, it is a general condition all through the country, embracing every business, every industry, and this cannot justly be said to apply for instance to the steel mills, or to the sugar industry, or the munitions industries. It all is interwoven. One has caused the other to grow and thus it concerns all the industrial activities of the country.

Packard to Pay for Employees' Citizenship Papers

DETROIT, MICH., Feb. 11—The Packard Motor Car Co. will pay the fees required of any of its alien employees who may desire to take out first papers toward American citizenship. This follows the announcement made Jan. 31 to the effect that only American citizens, or those of foreign birth who have relinquished their foreign citizenship and who have filed their applications for citizenship, will be given promotions to positions of importance, and that loyalty to the United States is a prerequisite to employment.

The company offers practical help in training foreign-born employees to become citizens. One class in English for foreigners is being conducted several nights a week at the factory, and two more classes are in preparation. Two welfare department men are studying the best methods of teaching English, to be able to qualify as instructors.

Vim Motor Truck Adopts Packard Scheme

PHILADELPHIA, PA., Feb. 12—The Vim Motor Truck Co., this city, has given notice that the Packard anti-hyphen scheme would be put into effect immediately in its plant. It has given notice that it will not advance men who fail to take out naturalization papers and file them with a view of becoming citizens of this country.

Tractor Show for Des Moines

DES MOINES, IOWA, Feb. 12—The Committee on Agriculture of the Des Moines Chamber of Commerce is arranging for the first annual Iowa tractor show to be held here this fall. A 1200-acre tract of land west of the city will be leased for the tractor demonstrations. Des Moines is to be on the midwest circuit of tractor shows. E. T. Meredith, publisher of *Successful Farming*, is chairman of the committee in charge of the arrangements.

Freight Car Shortage Becomes Serious Problem in Detroit and Toledo

Flats and Other Types of Car Are Adapted to Take Automobiles—Dealers Urged to Unload Promptly—January Shipments Break Records

DETROIT, Feb. 12—In spite of a serious handicap due to the shortage of automobile freight cars, Detroit automobile manufacturers managed to ship approximately 58,800 motor cars of the passenger type during January. This figure was obtained by a careful canvass of the concerns here and is a close approximation to the actual number. Yet this rather large shipment would have been much greater had the makers been able to secure all the railroad cars they wanted in which to convey the vehicles to their destinations. Although in many cases the number of automobiles that left the city was greater than ever before in the history of the concerns in question, there are other big producers whose shipments were curtailed as much as 40 per cent by the lack of railroad cars. One big maker, for instance, shipped a little over 3500 automobiles, and would have been able to ship 5000 could the freight cars have been secured.

Yet with this shipping situation and the materials markets troubling them, the car makers nevertheless enjoyed the largest January in the history of the business here, taking the industry collectively. It is an unusual thing for dealers to be crying for cars at this time of the year, and never before have they been so insistent for them when the winter months were on. In fact, so anxious have some of them become for cars that they have actually driven them over the snow-covered roads to their own towns rather than wait for freight shipping.

Number of Carloads

The traffic department of the National Automobile Chamber of Commerce has reported total carload shipments for the whole United States for January to be 18,054. Although in some cases less than five automobiles make up a carload, and in others the number is greater, it seems logical to say that each freight car would average five machines. On that basis, the number of freight carloads leaving Detroit in January was 11,760. This figures to pretty near 65 per cent of the total number.

However, there can be no disguising of the fact that freight conditions are bad. In most cases the automobile freight car is a special type, and while it is of use to other lines of industry as well as to the automobile maker, the latter is not in so good a position, for it is hard for him to utilize the other types of cars. But necessity has forced the traffic departments of the big companies to take whatever railroad equipment they can secure quickly.

Utilizing What They Can Get

As a result it is not uncommon to see big shipments of motor vehicles on flat cars, and in some cases they are even utilizing gondola and other types of coal cars. These they box over and really make very presentable box cars out of them. Some of the makers who have made use of flats are the Studebaker Corp., Maxwell, Paige, the Overland in Toledo and the Velie at Moline, Ill. Wherever possible these flat cars have so far been used only for the shipping of export cars to the coast. That is, the export machines are very tightly boxed and no harm can come to them through open shipment in similar fashion to harvesting machinery, etc. Where the run is comparatively short, Studebaker has been using flats in conjunction with heavy tarpaulins which they use very carefully to cover the cars against any weather conditions. The use of gondola cars is perhaps the most unusual adaptation of whatever can be secured in the way of railroad rolling stock.

According to the traffic bureau statistics, there are in use by the American railroads at the present time 68,235 automobile freight cars, and there is prospect of 10,000 more being added to this equipment in the very near future. This will give an enormous equipment designed for the special service of the automobile industry, which to-day has developed to the point where it is one of the chief sources of freight revenue of the railroads, but even with the added number it is doubtful if the supply will keep pace with motor car production. The railroads seem to be doing all they can to help the movement of motor cars, but they did not anticipate the demand and, although they have hastened to build more equipment, the difficulty of getting material has held up the placing of the additional freight cars in service. As a notable example of what the railroads are doing, it might be mentioned that the Santa Fe and other Western roads are sending trains of empties back to the automobile centers instead of holding them at their destinations for loads to take back.

In line with the endeavors of the railroads, the car makers are instructing their dealers that under no circumstances must they use the freight cars for storage of their machines, but they must unload them immediately on arrival. In the past this has been one cause of delay in getting the cars back, but it is believed that this situation has greatly improved, for the dealers recognize the need of coöperation for the good of all concerned.

A considerable factor in the present dearth of freight cars is the tie-up in the East, according to one of the traffic men here. His concern has sixty-nine carloads tied up in Norfolk, Va., waiting to be loaded on steamers, and doubtless there are many other such instances. There is no place to store the automobiles pending their being put on the ships, and consequently they are letting them lie in the freight cars. This is quite prevalent at all the export points, and is being practised by many of the makers. Due to this and other causes of congestion in the East, the Lake Shore, for instance, has been holding up shipments for eastern points as far back on its lines as Toledo. Then, too, other industries are demanding a great many cars, war shipments are very large, and the whole combination of circumstances at the present time is making it a puzzle to move the output. One day last week, as an instance, there were only fifteen automobile freight cars received in the whole city of Detroit. That, however, was an exceptionally bad day.

Shipping Costs More

A sidelight on the very serious shipping situation is the added cost to the car makers of each car shipped due to the troubles they have to go through in utilizing other than automobile box cars. Whenever flats have to be pressed into service, there is an additional item of expense where tarpaulins are used, for these have to be sent back to the factory. If it is necessary to box in a gondola car, there is a large cost item to be considered. Loading crews must be larger, and this adds to the cost. Taking everything into consideration, one big shipper of cars said that it costs from $2 to $3 more per automobile to ship them than it did when conditions were better and it was easier to get the right sort of freight equipment.

It is indeed deplorable that at a time when it seems impossible to meet the demand for cars, the makers should be handicapped by the shipping trouble. It has meant, and will continue to mean, curtailment of the production of cars to adjust the output to transportation facilities.

Evans Poyer Works Mgr.

MENOMINEE, MICH., Feb. 8—G. M. Evans, formerly with Dodge Bros., Detroit, has been appointed works manager of the D. F. Poyer Co., manufacturers of the Menominee trucks.

Buyer of Chalmers Car on Installment Plan May Have Immediate Delivery

Agricultural Credit Co. Purchases $5,000,000 of Installment Notes—6 Per Cent Interest—Fire and Theft Insurance for a Year Included in Sale of Car

DETROIT, Feb. 11—The Chalmers Motor Co. has made arrangements with the Agricultural Credit Co., Chicago, for the financing for dealers on the time sales of the Model 6-30 Chalmers car. This is the model which was brought out late last year and which sells for $1,050. By the plan which has been worked out the customer is required to pay $450 cash on receipt of the car and $32.50 to cover the cost of insurance for one year and interest. The balance he pays in eight monthly payments of $75. The item of $32.50 covers interest on the notes at 6 per cent and the actual cost of the insurance for a year against fire and theft on 80 per cent of the list price of the car.

The Agricultural Credit Co. buys the notes from the dealer or distributor less a very small brokerage. This concern is a large banking house which has carried on a farmer's credit plan for a number of years, enabling the farmer to finance his farm until revenues from crops came in, and its action in extending its field to cover automobiles is another instance of the recognition which high banking circles are taking of the motor vehicle industry. The directorate and official roster of the Agricultural Credit Co. contain the names of some of the foremost bankers of this country, and recently the directors authorized the purchase of $5,000,000 of installment notes taken on time sales of cars.

Pontiac Drop Forge Purchased by Jackson Capitalists

PONTIAC, MICH., Feb. 9—The Pontiac Drop Forge Co. has been purchased by Jackson capitalists, among them being Paul Leidy, secretary of the Jackson Board of Commerce, and Leigh Lynch, well known in Jackson automobile quarters. The capital stock of the company has been increased to $150,000. It is said that the production facilities will be greatly increased.

Monroe-Chevrolet Merger Denied

FLINT, MICH., Feb. 9—The Monroe Motor Co. will not be absorbed by the Chevrolet Motor Co. as has been rumored for some time. In fact, arrangements have been completed for the production of 10,000 Monroe cars this year and a new light five-passenger model will soon be announced. Its chassis and motor will be similar to those of the present model.

There have been negotiations between the Monroe and the Chevrolet companies concerning a possible consolidation of the two companies, but President R. F. Monroe states that this is a matter of the past and that the Monroe company will from now on become more active than ever before. That part of the plant which last year had been leased by the Chevrolet company is now again occupied by the Monroe company.

Pending the completion of the new Chevrolet axle plant the Monroe company will continue to make axles for the Chevrolet. It was also arranged that the bodies for the new Chevrolet Four-Ninety runabout will be made by the Monroe Body Co. in Pontiac. The Monroe company, which now employs 130 men, expects to have 700 on its payroll by June 1. Mr. Monroe has disposed of his stock in the Chevrolet company to Mr. Durant.

Supreme Court May Consider Price Maintenance Decision

WASHINGTON, D. C., Feb. 12—Accessory manufacturers and dealers will be interested to learn that for the third time the Supreme Court of the United States has been asked to consider the power of manufacturers of patented articles to control the price or conditions on which the public may obtain their product.

Attorneys for a prominent New York department store have filed with the court application for a review of the decision of the New York Federal Court of Appeals holding against its right to sell to the public at cut rates certain talking machines and records.

The problem of the right of patentees to control the resale of their goods to the public has proved one of the most perplexing questions the court has had to deal with in 10 years. First, in 1912, Justices Lurton, McKenna, Holmes, and Van Devanter, then a majority of the court, decided that a mimeograph manufacturer could control the kind of supplies to be used by the public on his machine. Chief Justice White, Hughes and Lamar dissented. Justice Day was absent and there was one vacancy.

About 2 years later Chief Justice White and Justices Day, Hughes, Lamar and Pitney decided a medicine manufacturer could not control the resale price at which the public bought its patented articles. Justices Lurton, McKenna, Holmes and Van Devanter then dissented. Justice McReynolds, who succeeded Justice Lurton, has not participated in any cases of this kind.

The New York store now claims that the principles of the medicine manufacturer case should be applied to "licenses to use" upon the payment of "royalties" because the "licenses" were only a cloak for a sale.

The court's decision will be awaited with interest by the automobile accessory trade.

World's Salesmanship Congress in Detroit July 9-13

DETROIT, MICH., Feb. 14—The World's Salesmanship Congress will be held here July 9 to 13. This was finally decided at the general committee's meeting today.

Bill to Bar Trucks Weighing Over 8 Tons from Maryland

ANNAPOLIS, Md., Feb. 12.—Under the provisions of a bill introduced in the General Assembly here no commercial motor vehicle with capacity of more than 8 tons will be permitted to operate in the State. The bill also proposes to greatly increase the license fees paid by all commercial vehicles. At present all the commercial vehicles in the State pay the flat rate of $3.00 a year. This bill which has been introduced provides that cars of this kind with capacity of not more than 1 ton pay $15 a year; those of more than 1 and less than 2 tons, $20; $25 for those between 2 and 3 tons; $30 between 3 and 4 tons; $35 between 4 and 5 tons; $40 between 5 and 6 tons; $45 between 6 and 7 tons, and $50 between 7 and 8 tons.

Olds Will Not Drop Four

LANSING, MICH., Feb. 9—According to general sales manager J. V. Hall, of the Olds Motor Works, the manufacturing of the Oldsmobile four will continue as long as there is a public demand for these cars and notwithstanding the great demand for the Oldsmobile eight. The statement was brought about on account of rumors that the four will be discontinued.

Elliott Is Mais Manager

INDIANAPOLIS, IND., Feb. 14—E. M. Elliott has been appointed general manager of the Mais Motor Truck Co. division of the Premier Motor Corp., Indianapolis. Plans have been completed to increase the production of the Mais company, and to add to the line of trucks hitherto manufactured.

Assembly Plant for Regina

REGINA, SASK., Feb. 11—The newly amalgamated Willys-Overland Automobile Co. and the Russell Motor Co. have made Regina headquarters for western Canada, and will erect an assembling plant.

To Finance Studebaker Sales

Commercial Investment Trust to Help Dealers on Deferred Payments—⅓ Down

Detroit, Mich., Feb. 11—Arrangements have just been completed by the Commercial Investment Trust, with offices in New York and St. Louis, whereby Studebaker dealers have been placed in an advantageous position to finance the sale of Studebaker cars on deferred payments. On either of the Studebaker models the dealer is able to offer to sell the car to the customer for one-third down and the balance in eight equal monthly payments. The buyer of the car pays the regular list price.

It often develops that an automobile buyer is anxious to get his car immediately but cannot pay the full amount at the time. Because of anticipated income, he can pay part and wishes credit for the balance. The plan of the Commercial Investment Trust enables the dealer to handle such sales without tying up his own capital, and is a particular advantage for the dealer working on limited capital. The notes which the dealer gets from his customers are converted into cash by the Commercial Investment Trust, which collects the notes.

The arrangement with the Commercial Investment Trust is not intended to interfere with local banking arrangements which Studebaker dealers have, but is a provision for more extensive banking facilities, at the option of the dealer.

The Studebaker Corp. states that it has no financial interest whatever in the Commercial Investment Trust, having simply been instrumental in effecting the plan for the benefit of its dealers. The Commercial Investment Trust and the Studebaker dealers handle their banking arrangements independently.

Gasoline Up in West

New York City, Feb. 11—Gasoline prices in this city, which reached the 23-cent-a-gallon mark, wholesale, last week, show no indications as yet of a further rise.

In Oklahoma and Colorado, this fuel has been advanced 1 cent to 22. Prices in Montana have been advanced ½ cent. South Carolina prices have risen 1 cent; now ranging from 24½ to 26½ cents.

In Portland, Ore., gasoline, tank wagon basis, is now selling at an advance of 1 cent to 17½. In Los Angeles the price prevails at 17 cents, just 1 cent higher. Louisville, Ky., gasoline is selling, tank wagon basis, at 21 cents at an advance of 1 cent.

The price of gasoline has been advanced 1 cent a gal., tank wagon basis, to a minimum of 22½ cents and a maximum of 25½ in Arizona, to a minimum of 22 cents and a maximum of 24 cents in Florida, and to a minimum of 22½ and a maximum of 25 in Georgia.

15 Per Cent Dividend Declared by Streator Trustees

Streator, Ill., Feb. 14—Creditors of the defunct Streator Motor Car Co. were notified this week by E. U. Henry, referee in bankruptcy, that the trustees have collected $38,633.61, sufficient to declare a dividend of 15 per cent. A meeting was held on Feb. 16 to ratify this dividend and also to discuss the disposition of the remaining real estate belonging to the bankruptcy estate. This real estate has been appraised at $75,000 but the trustees have been unable to receive any substantial bid for it. It is desired to wind up the concern, as all the assets have been realized upon with the exception of the real estate mentioned.

Market Prices Steady

New York City, Feb. 15—With the exception of a further rise of 2 cents a pound to 56 cents for aluminum and a 10-cent rise in lead, market prices last week were fairly steady with few changes. Rubber was a little higher, though it has not as yet reached the high mark of several months ago. Para rubber is now quoting at 78, while the Ceylon, first latex pale crêpe grade, is quoting at 90. The demand for rubber has increased from the manufacturers. Most of the sales, however, were made on spot.

Though no change has been made in copper prices, the market in that metal is active with the movement of quotations continuing decidedly upward. It has been estimated that domestic consumption is now at the rate of about 150,000,000 lb. a month.

Crude oils have been very steady during the past two weeks, Pennsylvania holding at $2.35 a bbl. and Kansas crude at $1.30. Gasoline still quotes at 23 cents a gal.

Mason Tire & Rubber Co. to Make Capital $1,000,000

Kent, Ohio, Feb. 11—The Mason Tire & Rubber Co. has awarded contracts for nearly $80,000 worth of buildings and equipment. The directors have determined to raise the capitalization if the stockholders approve it.

At a meeting of the board of directors in the company's offices a resolution was passed authorizing an increase in capitalization to $1,000,000, and calling for a general stockholders' meeting within a few weeks to ratify and approve the action.

Studebaker Declares Extra Dividend of 1 Per Cent

South Bend, Ind., Feb. 14—The Studebaker Corp. directors declared the regularly quarterly dividend of 1¾ per cent of preferred stock and a quarterly dividend of 1½ per cent with an additional extra dividend of 1 per cent on common stock. These dividends are payable on March 1, 1916, to stockholders of record at the close of business Feb. 19, 1916.

Johns-Manville Elects Directors

New York City, Feb. 14—At the annual meeting of the H. W. Johns-Manville Co., L. R. Hoff, W. R. Seigle, T. T. Lyman, H. R. Trainer, Harry Gillett, F. B. Smith, J. E. Meek, H. R. Wardell and J. W. Perry were elected members of the board of directors.

M. & A. M. Adds Seven Members

New York City, Feb. 11—At a meeting of the board of directors of the Motor and Accessory Manufacturers, held in the association's offices to-day, the following concerns were elected to membership:

Blanchard Bros. & Lane, manufacturers of patent and enamelled leather, Newark, N. J.; Flint Varnish & Color Wks., manufacturers of varnish, paints, and enamels, Flint, Mich.; Harrison Mfg. Co., Inc., manufacturer of radiators, Lockport, N. Y.; Price Electric Devices Corp., manufacturer of lighting and ignition generators, starting motors and

battery charging outfits; automatic cut-out switches, Waynesboro, Va.; Syracuse Malleable Iron Wks., manufacturers of malleable iron castings, Syracuse, N. Y., and the Walker-Weiss Axle Co., manufacturers of automobile axles, Flint, Mich.

The Driggs-Seabury Ordnance Co., manufacturer of automobile parts, Sharon, Pa., was reinstated to membership.

Detroit-Wyandotte Elects Officers

WYANDOTTE, MICH., Feb. 11—At the annual meeting of the Detroit-Wyandotte Truck Co., which makes the Horner, the following officers were elected: G. A. Horner, president and general manager; Frank Marx, vice-president and treasurer; R. A. Parker, secretary. These officers and Otto Schmidt and M. C. Wick form the board of directors. Because the plant is to be enlarged and production facilities increased, no dividend was authorized.

Dividends Declared

Pratt & Whitney; quarterly, 1½ per cent on preferred, payable Feb. 15 to holders of record Feb. 9.

Maxwell Motor Co.; quarterly of 1¾ per cent upon first preferred, payable April 1 to stockholders of record on March 10.

Recent Capital Increases

TOLEDO, OHIO, Feb. 11—The Pilloid Motor Co. has increased its capital from $50,000 to $100,000.

CLEVELAND, OHIO, Feb. 11—The Ohio Rubber Co. has increased its capital from $250,000 to $300,000.

Security Prices Higher

General Motors Features Automobile Issues with 30-Point Gain—Chevrolet Is Up 4

NEW YORK CITY, Feb. 15—A better tone developed last week in the automobile and accessory issues. A majority of the issues showed substantial gains for the week with General Motors common the feature. This stock has been going steadily down from its high mark of over 500, its bottom price being under 425. Saturday it reached 475, going up 5 points over night and 30 points for the week. Chevrolet went up 4 points to 130. Overland common rose 1 point to 221 after a 19-point rise the previous week.

Deposits of Maxwell Motor warrants for conversion into first preferred stock are being received by the company steadily, and it is expected that a large proportion will have been exchanged by March 10, which is the stock of record date for the April 1 dividend on the first preferred. Holders of warrants must exchange before March 10 to receive this dividend. These warrants were issued in January, in payment of 14½ per cent back dividends on the first preferred stock.

Sales of the International Motor Co. in January increased 36 per cent over those of a year ago. Domestic sales for 1915 increased 20 per cent over 1914.

Activity in the rubber issues was more marked last week. Ajax went up 2¼ points; Goodrich common rose 1½ points, while its preferred went up 1 point; Goodyear common rose 3 points; and U. S. Rubber common and preferred went up 1½ and 1 points respectively. Kelly-Springfield's new common went up 1 point. Ajax reached a new high record of 72 7/8 in the outside market Monday on large sales. An officer of the company announces the completion of arrangements covering its requirements for the year, the largest stocks of crude rubber ever warehoused by that company, all purchased at prices which now protect the company's profits.

Detroit Exchange issues were exceptionally strong last week. Continental, General Motors and Studebaker featured with large gains. Continental, especially, has been a matter of much comment on the Detroit Stock Exchange. Thursday morning, Feb. 10, the stock was quoted at 292. Friday morning it rose to 327½ and at the close of the exchange there were bids at 350 and a few offerings at 360. Less than one month ago the quotation was 247 bid and 255 asked, or a gain of over 100 points.

General Motors Sales $74,000,000 in Six Months

NEW YORK CITY, Feb. 16—Earnings of the General Motors Co. for the six months ending Jan. 31 are reported to be equal to 150 per cent on the common stock. Gross sales increased 100 per cent, amounting to $74,000,000. Undivided profits were $13,000,000, also 100 per cent larger than in the preceding six months. These profits are sufficient to take up within $2,000,000 of the entire outstanding preferred stock of the company.

Corona Grand Prix April 8

Will Be Held Over 300-Mile Course—$12,000 in Prizes

Corona, Cal., Feb. 8—The Corona Grand Prix is to be staged on the Grand Boulevard around the city on April 8. The directors of the Citrus Belt Racing Association, the organization which is guaranteeing the $12,000 purse for the race, announced that it could not stage the race on March 17, as originally planned, when the extent of the damage to the roads caused by the recent storms was made known. Then, when the decision of the Motor Cups Holding Association was published, refusing the International Grand Prix to Corona, the local boosters decided that they had better pass up the race this year. At a special mass meeting of the citizens it was decided to reconsider this action, and the racing association directors met and decided to stage the race on April 8 over a 300-mile course for the original $12,000. The official name of the race is to be decided upon at a later date, but it is almost certain that the event will be known officially as the Corona Grand Prix.

Elgin May Try for Vanderbilt and Grand Prize

Chicago, Ill., Feb. 15—At a meeting of the Elgin Road Racing Association, scheduled for Feb. 23, plans will be made for the annual meet on the Watch City course. There is some talk in the air of Elgin applying for the Vanderbilt cup and Grand Prize and running these two classics at the same time that the Elgin National trophy and the Chicago Automobile Club cup are hung up for competition. If this suggestion is favorably acted upon, Elgin will have a week of road racing, the meet opening and closing on Saturday with events on the intermediate Tuesday and Thursday. The prize money will be the same for each of the four contests, $6,000, and $20,000 of the $24,000 total purse will be raised by the sale of 2000 tickets, listed at $10 each and entitling the holder to admission to all four events.

Maxwell Racing Cars to Have New Bodies

Detroit, Mich., Feb. 8—New bodies, different color scheme, and more speed will characterize the appearance upon the race courses this year of the four Maxwell racing cars now owned by the Prest-O-Lite Co., Indianapolis.

The bodies will be narrower and the driver and mechanic will ride much lower than during the past year. Red and white will be the colors. According to Eddie Rickenbacher, who will be captain of the team, the cars will be capable of going 4 or 5 miles faster per hour, which means 109 to 110 m.p.h. Rickenbacher expects to have two teams, racing pairs alternately at different meetings. Ray Harroun, who designed the cars and supervised their construction, will give advice to Rickenbacher. Whatever improvements or parts for the cars are needed will be built at the plant of the Maxwell Motor Co. here.

Santa Monica Wants Grand Prix and Vanderbilt

Santa Monica, Cal., Feb. 8—There may be a race on the famous Santa Monica road race course in 1916. The Santa Monica Chamber of Commerce has endorsed the movement to secure the International Grand Prix and the Vanderbilt Cup Race for Santa Monica next November. The course is now being put in the best possible condition, with nine months in which to prepare for the speed carnival.

The revival of automobile racing at Santa Monica came as a surprise to the most enthusiastic sportsmen of the beach city. Last year all efforts at arousing interest in racing fell flat. Three times this year, meetings were called for the purpose of stirring up interest in the motor sport, but there was nothing done toward putting on a race. But when the Motor Cups Holding Association refused to grant either the Vanderbilt Cup or Grand Prix for any course less than 8 miles in length, Santa Monica woke up. Two meetings were held and a committee was appointed to make formal application for the two races which were so successfully staged at Santa Monica in 1914.

Sioux City To Buy Cars

Sioux City, Iowa, Feb. 16—E. R. Schultz, manager of the Sioux City speedway, now is negotiating for the purchase of two Duesenberg cars, which will be constructed by Fred Duesenberg of St. Paul and entered in the various speedway events this season under the name of the local racing association. This deal, which is practically closed, will bring the total of speedway-owned cars to twelve. Indianapolis has eight, the four Maxwells, the two Peugeots and the pair of Premier Specials, and New York two Delages, one purchased by Harry Harkness in the fall and the other by Carl Limberg in France this winter.

Continental Needs More Men

Muskegon, Mich., Feb. 10—The shortage of mechanics and other skilled workers is said to be the reason why the Continental Motor & Mfg. Co., this city, is advertising extensively throughout the country for such workers. The business here is growing to such importance that within the next twelve months the company is expected to have 5000 men or more on its payroll which is at least one-third more than at present.

It is said the daily output of motors now averages 175, whereas it should be at least 225 per day. At the former figure and based upon 300 working days the output for the year would be 52,500 motors while at the higher figure or 225 it would be 67,500.

Arrangements and plans are already under way to provide for an average daily output of 400 motors during 1917 which is at the rate of 120,000 for the year.

Wheeler is President of Twin City Motor Speedway Co.

Minneapolis, Minn., Feb. 14—F. H. Wheeler has been elected president of the Twin City Motor Speedway Co. H. E. L. Habighorst was elected vice-president, and E. E. Gates, secretary and general counsel.

It was definitely decided to hold the opening race of the 1916 season May 31 and the 300-mile race July 4. A date for the fall races will be decided upon at a later meeting of the company.

N. Y. City Fines Total $417,299

New York City, Feb. 14—Fines from traffic violations and speeding in 1915 cost automobile owners just $417,299, of which $223,618 was from traffic division and $193,681 from the motorcycle squad.

From the office of Police Commissioner Woods the following statement of the total number of arrests in 1915 and the amount of fines for traffic violations is given:

	Traffic Divisions	Motorcycle Squad
Arrests and summonses .	22,983	13,319
Convictions	22,554	13,119
Fines	$223,618	$193,681

Disbrow to Handle Marmon

Cleveland, Ohio, Feb. 11—Louis Disbrow, the well known racing driver, has quit the racing game for good and has organized the Louis Disbrow Motor Car Sales Co., which will handle the Marmon in Cleveland and nine adjoining counties. The officers of the newly organized company are: Louis Disbrow, president; M. A. Hanna, vice-president; D. B. Hanna, Jr., treasurer and Fred Grabien, secretary.

U-S-L To Add 1150 Men

New York City, Feb. 11—The United States Light & Heating Co., which now has 850 men on its payroll will increase its force within the next two months to at least 2000.

Factory Miscellany

Continental Top Makes Lease—The Continental Auto Top Co., St. Louis, Mo., has leased a building at 818 North Leffingwell Avenue, St. Louis, and will remodel the same for the manufacture of automobile tops.

Knapp Top to Build—The A. C. Knapp Co., manufacturer of automobile tops, has awarded the contract for the construction of a one-story addition to its plant at Detroit, Mich.

Chandler to Add—The Chandler Motor Car. Co., Cleveland, Ohio, will erect an addition to its plant at 300 East 131st Street, to cost $18,000. The addition will be 62 by 162 ft., with foundations sufficiently strong to carry additional stories.

Parish & Bingham to Build—The Parish & Bingham Co., Cleveland, Ohio, is to spend $250,000 on several new factory buildings. Present intentions are to build a fireproof addition, 100 ft. wide, to the main building and a small addition to the power house. Later the company intends to build a service station 80 by 220 ft. and three stories high and a steel storage building 54 by 87 ft., one story high.

Plymouth Motor Castings Plant Increased—The production facilities of the Plymouth Motor Castings Co., Plymouth, Mich., are being increased through the addition of equipment and enlargement of the plant.

Eagle-Macomber Plant in Sandusky—The Eagle-Macomber Motor Car Co. will establish a plant and main office in Sandusky, Ohio. The building formerly occupied by the Suspension Roller Bearing Co. will be used for assembling purposes.

To Make Brass Castings—Gallagher, Hutchinson & Campbell Bros., Muskegon Heights, Mich., have secured a factory at Marshall, Mich., and will remodel it for the manufacture of iron, brass and aluminum castings for automobiles.

Price Electric Devices to Build—The Price Electric Devices Corp., Waynesboro, Va., will establish a plant at Basic, Va., for the manufacture of lighting and ignition systems, starting motors and other automobile equipment.

Light Car Axle to Move—The Light Car Axle Co., successor to the Clark Delivery Car Co., 1035 East Seventy-sixth Street, Chicago, Ill., will move its plant to Kalamazoo, Mich. New equipment will be added.

Auto Trimmings Co. Builds—The American Auto Trimmings Co., Detroit, Mich., is building a five-story reinforced concrete plant at a cost of $45,000.

Long Co. to Add—The Long Mfg. Co., Detroit, Mich., maker of automobile radiators, will build an addition to its plant.

Turner & Moore to Build—The Turner & Moore Mfg. Co., Detroit, Mich., maker of automobile parts, is having plans prepared for a factory, 75 by 300 ft. New machinery will be installed, including power equipment.

Ford Kansas Plant Enlarged—Additions to the assembling plant of the Ford Motor Co., Kansas City, Mo., that have been under construction since last May, practically doubling the capacity, have just been completed and the output has been increased from seventy-five or 100 cars a day to 130. The output will be increased later to 150 cars daily.

The opening of the addition brought with it an increased employment of about one hundred workmen in the Kansas City plant.

The Week in the Industry

Godheart All-Steel Sales Manager—Louis Godheart, who was traveling representative of the Lewis Spring & Axle Co., Jackson, Mich., has been appointed sales manager of the All-Steel Motor Car Co., Macon, Mo.

Pearson Promoted—C. E. Pearson, who for the past 15 years has been electrical engineer of the National Coil Co., Lansing, Mich., has been appointed general manager.

—

Dealers

News Items from Alabama—The Brownell Auto Co., Birmingham, Ala., has secured the agency for the Studebaker. This concern also handles the Ford in that territory. Joe Anderson, who formerly was the Studebaker agent, has acquired the Franklin line.

Willingham Sons' Manufacturing Co., who are the makers of Superior trucks in Atlanta, have established a factory branch at Birmingham, Ala., at 213 Twentieth Street, South. H. R. Leadbetter will have charge.

American Malleables' Detroit Office—The American Malleables Co., with plants in Owosso, Mich., and Lancaster, N. Y., has opened an office in Detroit, in the Kresge building, in charge of assistant sales manager P. G. Smith.

Represents Acme Die Castings—Niedermiller & Ewald, 965 Woodward Avenue, Detroit, Mich., have been appointed Michigan and Ohio representatives for the Acme Die Casting Corp., Brooklyn, N. Y.

Ohio Trade Items—The Columbus branch of the Midgley Tire Co., formerly located at 224 North Fourth Street, has moved to 85 East Gay Street, with E. E. Loeer in charge as manager.

Formal renewal of the contract between the Maxwell Motor Co. and the Everitt Auto Sales Co. of Columbus, by which the latter concern continues as central Ohio distributor for the Maxwell, has been made.

The Lober Art Brass & Specialty Co, Toledo, has occupied its new home at 126 Eleventh Street. The concern makes and repairs radiators and automobile lamps.

Harding Takes Showroom—The new Harding Motor Car Co. has taken a temporary showroom at 1824 Euclid Avenue, Cleveland, Ohio, and expects to close negotiations for its permanent sales quarters and factory site in the near future.

Motor Men in New Roles

Cornell Appointed Cleveland Mgr.—E. J. Cornell has been appointed manager of the automobile tire department of the Haury Hardware Co., which is distributor in Cleveland of Goodyear tires.

Hubbard Promoted—H. H. Hubbard has been appointed assistant manager of the territory west of the Mississippi River by the United States Tire Co., New York City. He has been manager in St. Louis, Mo., for the company for four years, and will continue to make St. Louis his headquarters. O. S. Johnson, who has been Texas manager for that company, succeeds Hubbard at the head of the St. Louis branch.

McKay Joins Cassidy—D. C. McKay has resigned as Detroit factory representative of the H. W. Johns-Manville Co. to represent Edward A. Cassidy, New York City.

Titus Goes to Buffalo—F. E. Titus has been appointed general manager of the Goodrich branches in Buffalo, Rochester and Syracuse, his headquarters being in the first city named. He was for a long time manager of the Pittsburgh branch of the company.

Prey Scripps-Booth Purchasing Agent—H. C. Prey, who was assistant purchasing agent of the Scripps-Booth Co., Detroit, Mich., has been made purchasing agent to succeed A. J. Downey, who will henceforth devote all his energies to the Scripps Motor Co., Detroit.

Harger Succeeds Corman—R. H. Harger is now in charge of the advertising department of the Saxon Motor Car Corp., Detroit, Mich., in place of E. W. Corman, who resigned.

Levey in Accessories Business—W. B. Levey, formerly buyer for Auto Parts Co., Chicago, has formed the Automobile Accessories Co., Chicago.

Hipple Mitchell Merchandising Counsel—G. W. Hipple, recently vice-president and general manager of the Carl H. Page Motors Co., New York City, has been secured by the Mitchell-Lewis Motor Co. to act as general merchandising counsel.

Sherwood Gibney Branch Manager—F. W. Sherwood has been appointed branch manager of the New York City sales and service departments of the Gibney Tire and Rubber Co.

Jenkins Transferred to Detroit—S. S. Jenkins, who was manager of the Indianapolis branch of the Willard Storage Battery Co., during the past 4 years, has been appointed district manager at Detroit. M. G. Hillman, who was in charge of the Detroit branch, has resigned, and his assistant, E. Resser, has been made manager of the Indianapolis branch.

Radford and Block Combine—H. R. Radford, who was vice-president and general manager of the Cartercar Co., Pontiac, Mich., and W. D. Block, who was comptroller, have formed the Radford-Block Co., to handle the Oakland cars in Detroit and vicinity. Headquarters have been opened at 1225 Woodward Avenue.

Dealers

Wisconsin Trade News—The Curtis Automobile Co., Milwaukee, for many years located at 142-144 Eighth Street, has leased the large garage and service station building directly opposite, at 143-147 Eighth Street, occupied by the Ford Motor Co.'s Milwaukee branch until the opening of the new $300,000 assembling plant several weeks ago. The Curtis company is distributor of the Reo cars and trucks.

Harry Kohn, until recently manager of the Wisconsin Auto Exchange, 115-117 Sycamore Street, has organized the Paramount Auto Exchange and established a clearing house for used cars in the garage at 142-144 Eighth Street, Milwaukee, which has just been vacated by the Curtis Automobile Co.

The Dicke Motor Car Co., Manitowoc, Wis., has established a branch garage and service station at Two Rivers, Wis., in the former Hamacheck garage. The business will be operated as the Two Rivers Automobile Co. under the management of Walter Whitney.

The Enger Motor Sales Co., Eleventh and Wells Streets, Milwaukee, organized by R. D. Mitchell and E. A. Glab to act as State distributor of the Enger Twin-Six in Wisconsin, has been appointed State distributor of the Pathfinder Twin-Six.

New York City Items—The Carl H. Page Motor Co., New York City distributor of the Mitchell car, has leased the large point store in the American Circle Bldg. at the junction of Broadway and Central Park West, the north end of Columbus Circle.

C. T. Silver has opened another branch in Yonkers, adjacent to New York. The branch is located at 1 Manor House Square.

December 28, 1915
Patent No. 1165861

Hudson Super-Six

A Small, Light Six Delivers 76 Horsepower

THE Super-Six motor has a cylinder capacity of 288 cubic inches.

This size develops some 85 horsepower. But heretofore, at its best, it delivered 42 horsepower. Some 50 per cent was lost in vibration and friction.

The Super-Six delivers 76 horsepower. In this patented motor only 10 per cent is lost in vibration. Thus friction loss is reduced 80 per cent. And that gives to the motor almost double endurance.

JUST WASTED POWER

This extra 34 horsepower is simply power that heretofore was wasted. We have added no cylinders or size. We have not increased fuel consumption.

All the advantage of the Super-Six lies in its utter smoothness. It shows in bird-like motion. The motor is small and light —same size as the Hudson Six-40. It is very economical because of the saving in friction. Rarely does this motor run at more than half load. And the engine wear is almost eliminated.

NOW SUPREME

It must be conceded that the Super-Six motor makes the Hudson car supreme. It has broken all stock car records.

No other type—Six, Eight or Twelve—can approach the Super-Six in performance.
